as may be, to look like a Jack-in-the-Green. Every branch is thus exposed to the sun and light, and upon every branch there we get pears. We pass now from pears to plums, and from those to grape vines, and on to nut trees, where you must notice the two blossoms, one, the catkins, being the male, which comes out early in January and February. The female is a little red flower, which is overlooked by most people; but I need scarcely say that both males and females must be present in our plantations, or there will be few nuts.

As for plants, I am, like everybody else, a lover of ferns. Fern roots do not like to be soddened in water and do not like to be dry; now you must find the happy medium. They should be never dry, ever moist, and yet neither too dry nor too moist. The best way to manage that is to plant them upon a bank. And what happens? There is always moisture draining through the earth, and the wet is always running away from the roots, and if you plant them in that way you will have as luxuriant specimens as are to be seen anywhere. Now ferns, you know, as a rule like a little shade, not too much however. There are some which will bear the full blaze of the sun. The *Osmunda regalis* and several other ferns bear well the light of the sun, but next in order we come to those delicate ferns which will not bear so much light, and these we must put in another situation. I have never succeeded in growing the fern of Tunbridge Wells, out of doors. It is most delicate, and is altogether a most charming plant. But the way I can manage, with most perfect success, is to bury in the ground a little square box, put in the fern and then put a piece of glass over it; that is sufficient to protect it from the wind and to keep up a continual moisture, and it never gets materially frozen, and so, many of these tender ferns may be grown in perfection. I have grown in this way that wonderful fern which was discovered by Captain Cook in New Zealand, the *Todea superba*; so you will see what may be done by a simple protection of glass. Sometimes we adopt other plans, we make a little pocket for the plant by putting two or three stones round it in a little hole, and so it has the advantage of full light and air and yet is protected. There are many exotic ferns, however, which will grow out of doors as well as the English ferns, but we carry them outward growth to a greater extent by housing some of the delicate ones in the winter and putting them out of doors in the summer. In this way the large tree ferns will grow, and show their forms remarkably well. To go into my fernery in winter when all there is beautiful and green, and then to come out and regard the snow and ice, and naked trees, is an effect which is as remarkable as it is beautiful. Of alpine flowers I have many hundreds. They can be grown with perfect success on one condition, that you allow no one to dig amongst them, and that you leave them carefully alone as soon as they are established. I know of no greater pleasure than to select your flowers on the mountain and bring them home to plant in your garden, and then to see them as reminiscences of the beautiful scenes you have before seen. My alpinery is a very delightful place to me. I always go there to see what flower is out; the last was the Lily of the Field of the Bible. Then there are the Saxifrages, and the Grass of Parnassus, which was thought so beautiful as to be dedicated to the Muses. Then there is another plant in the alpinery which I must notice, the Linnaea borealis. It is the smallest of all the honeysuckles, and that great naturalist, Linnaeus, chose it as a type of himself, because it had so lowly an origin. He obtained permission to use it as his coat of arms. It is a very scarce plant, and I can hardly describe the pleasure I have found in seeing it in a wood in Abergavennyshire. We are not restricted to foreign plants, our very woods and fields are beautiful with flowers. There is no more beautiful plant than the marsh marigold; to see it growing in spring, is a sight not to be forgotten. Its perfection of form renders it a plant which is one of the beauties of our streams. The purple loose-strife which grows by the banks of the Thames renders them a perfect flower garden. When we find the wild digitalis, the wild violet, the wild honeysuckle, and many other plants, we may say there is a beautiful flower garden in our woods. I was never more struck than when I saw some drawings of some wild flowers; I found that we had put aside for our garden flowers others which had higher claims. The time has nearly run out, but am I not to speak of my orchids, my bees, and my flies? Am I not to speak of the man orchid, which looks as though a little man were dangling from the flower? This is to be found within a few miles of London. The curious fly orchid is not far off and must not be forgotten. The dove orchid has in its flower a figure of a dove, spotless as ivory. It is looked upon with considerable superstition by the Spaniards in Central America where it grows. I cannot describe the many plants we grow, and it would take much longer to describe the plants. A garden must ever be a source of pleasure to a man: it helps him over his troubles, soothes his nervous system, and carries his mind from the beautiful things which grow there to the Author and Designer of them all.

[FEB. 3, 1873.]

THE FLOWER-GARDEN

ROSES AND ROSE CULTURE.

BEFORE I continue my catalogue of those roses which I have proved to be the most vigorous in constitution, and which I specially commend to the young rosarian as most likely, from their "staying qualities," to encourage and extend his ambition, I must reply to the inquiries and observations of my friend Mr. Fish (p. 203), concerning certain varieties already noticed and commended. To hold converse with such a congenial spirit must always be to me a happy employment, and it is so more particularly on the present occasion, because I venture to hope that some readers of THE GARDEN may be interested in the discussion of two veteran florists,—

Arcades ambo,
Et cantare pares et responderes
parati,—

may perhaps learn something from our experience, and be induced to communicate their own.

With regard, in the first place, to Souvenir de la Malmaison, of which Mr. Fish complains that, out of doors it is so hard-hearted and unsatisfactory, that he has almost given up growing it, I most earnestly say to him, as *Punch* to persons about to marry, "Don't." Because, although it rarely succeeds at all, and is short-lived at best, upon the briar, and although in a cold or wet summer its first buds are deformed and decayed, it rarely fails when once thoroughly established upon its own roots (in no other form will it prosper continuously) to produce in the later summer, and especially in the

autumn, its lovely roses. Being, like all Bourbons, of tender constitution, it must have a good warm overcoat of farmyard manure put on towards the end of November, and then, though the upper shoots may be blackened by frost, it will come out in force from the roots in spring. Again and again I have cut away in March the dead wood from this ancient stump, until nothing was to be seen above ground; but soon the new growth began to break, like heads of asparagus, around; and, as I stated before, plants purchased and planted in 1846 still continue to yield beautiful roses in our cold Nottinghamshire clay. And I have but three more words to say on this subject to my friend, or to any other brother rosarian,—"Come and see."

In the next place, and with reference to the two Devonianus, *mère et fille*, my good brother not only accuses me of preferring

the daughter to the mother (an infirmity common to man), but, in his enthusiastic admiration of the older variety, he decries and disparages the new. Let me say, that I only passed over Devonianus senior because the list which I am giving in THE GARDEN is restricted to roses which are perfectly hardy; that I quite agree with him that there is nothing lovelier than this variety in its most perfect phase; and that if any eminent composer will prepare a duet in its praise for myself and Mr. Fish, to sing at the next congress or conversazione of the Royal Horticultural Society, I will endeavour to learn my part.

But he is mistaken about the daughter. He can never have seen it, as I and others have grown it, upon the hybrid Bourbon (Céline) stock sixteen feet

in height, and bearing an abundance of roses, quite as beautiful as the parental flower. It is, as he says, too delicate for outdoor cultivation; and yet I still possess upon a wall one of the original trees sent to me by Mr. Curtis, of the Devon Nursery, Torquay. The proper place for Climbing Devonianus is in a rose house, and then, carefully treated, it is, in April, exquisite. Why they who grow flowers for the London market have not cultivated this rose more extensively I am at a loss to know, unless its blooms are too large for the button-hole.

On the the third count I must plead guilty. I did not express myself adequately as to soil. The sentence should have been, "A mellow loam in which, when it has been double dug, a walking-stick may be readily pushed into it up to the handle." His comments are perfectly just upon the remark as it stood, and I correct my error with apologies and thanks.

And now I must conclude my list of weather-proof roses, too few in number, ere the time of planting be past.

S. REYNOLDS HOLE.

Yucca pendula.

best species of the genus, considering its graceful and noble habit simply invaluable in every garden. It grows about six and a half feet high, the leaves being at first erect, and of sea-green colour, afterwards becoming reflexed, and changing to a deep green. Old and well-established plants of it standing alone on the grass are pictures of grace and symmetry, from the lower leaves which sweep the ground to the central ones that point up as straight as a needle. It is amusing to think of people putting tender plants in the open air, and running with sheets to protect them from the cold and rain of early summer and autumn, while perhaps not a good specimen of this fine thing is to be seen in the place. There is no plant more suited for planting between and associating with flower-beds, for isolation or cold groups, on the turf of the pleasure ground, for large vases, and for bold rocky banks.

YUCCA PENDULA.

This is one of the very

DESERTED FAVOURITES.

THE WHITE LILY.

AMONG our grandest "old-fashioned" flowers, no garden favourite ever held higher rank than the White Lily. It has formed the theme of poets, the model of painters, and has been the symbol of spotless purity, and of youth and beauty, from time immemorial. Among garden flowers it is fairest among the beautiful. Matchless in its snowy whiteness and exquisite form, it seems loftily to disdain the aid of the fairest hues. It would, indeed, be as futile "to gild refined gold," as Shakespeare has said, as to "paint the lily"; for, in fact, colour would but detract from the proud chasteness of this stately flower. It is one of those fine old plants with which we have been associated from our youth, and therefore must not be discarded, even to give place to the golden-rayed Lily itself.

How grandly the tall groups of White Lilies used to rise in early summer among the me old border flowers, before they were all uprooted and banished to make way for the monotonous, "ribbon system," or geometric masses of less worthy flowers! How much more interesting than such plants, or such a system of culture, were those great clumps of aspiring Lilies that appeared every successive spring on a well-known spot, and with their upright growth contrasted so finely with the horizontal lines of our old, old terrace walls, relieving their monotony by rising above their upper lines, whose course they interrupt with a mass of floral beauty that made the cold sculpture of the marble vases and their pedestals look poor and pale in comparison with the living forms and dazzling whiteness of the sculpture-like flowers!

One cannot wonder that the Lily became long ago an emblem of purity and beauty; nor that, as Chaucer tells us, St. Cecilia's name was derived from Cœli lily, the Lily of Heaven,—

"First I will to you the name of St. Cecile
Expound, as men may in her story see;
It is to say, in English, Heaven's Lily,
For pure chastenesse of virginity."

Shakespeare, as is well known, took many of his happiest similes from flowers; and in the following might almost appear to have foreseen the neglect and banishment of the Lily from our gardens, when he makes a stranger in his own land exclaim,—

"Like the Lily,
That once was mistress of the field and flourished,
I'll hang my head and perish."

There would be no end to quoting all that poets have said

of the "white-plumed" lilies, as Keats called them; but the lines of Ben Jonson, in which he turns the fair image of the Lily to exceeding good account, must not be passed over,—

"It is not growing like a tree
In bulk: doth make men better be;
Or standing still, as men are hundred year,
To fall a log at last, dry, bald, and scar:
A Lily of the day;
Is fairer far in May;
Altho' it fall and die that night,
It was the flower of light."

Nor can Cowper's happily-conceived characteristics of the Lily be omitted; they are so extremely apt, and so like, that they may be taken as an accurate portrait, though by the hand of an accomplished painter, who always knew how to seize upon the best points of his sitters. It is in his short poem describing the rivalry of the Lily and the Rose that the following lines occur:—

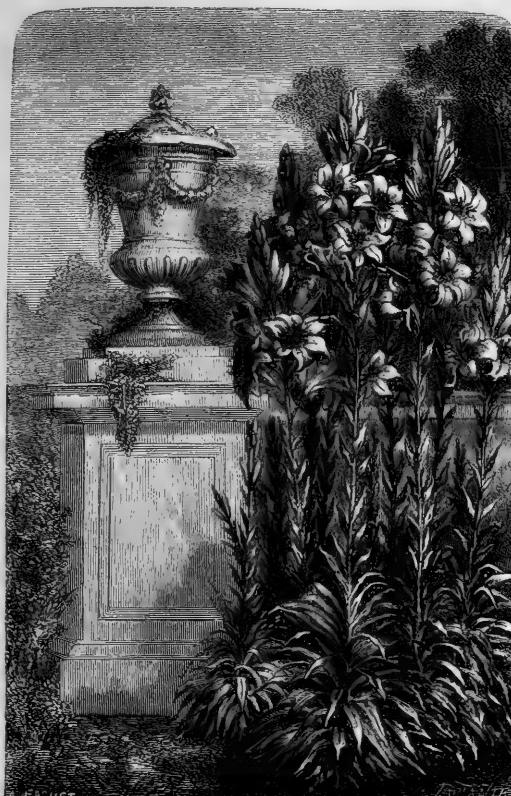

"The Lily's height bespoke command,
A fair imperial flower;
She seemed designed for
Flora's hand,
The sceptre of her power."

Seeing how the most gifted of our flower lovers, our greatest poets themselves, have admired the beauty of the White Lily, we may fairly hope that we will not persist in perversely refusing ducourt, as of old, to the undoubted queen of border flowers; neither neglecting her culture for weedy novelties nor gaudy masses of glaring pelargoniums (which yet have high value in their proper place). Let, then, the lily once more reign supreme in our flower borders, among many other deserted beauties, who must be recalled from banishment to form her court. Let not the shortness of her summer career be deemed a defect—her single month of glory is worth a whole summer's bloom of meaner flowers. There is the month of lilacs and laburnums to precede her reign, and the months of roses to follow, and the noble autumn flowers afterwards. There is something more attaching and interesting in the visits of these plants, that come

and lavish their beauty upon us for a golden month, and then bid us adieu till another summer, than in those flowers that bloom on monotonously month after month, lingering with us till their very presence is unnoticed; while the advent of the first lilacs, the first lilies, the first roses, for their brief stay, mark so delightfully the growth and progress of each garden year, from early spring-tide into the midst of high summer, and on to golden autumn.

FLOS.

Sweet Peas (see p. 162).—It has been our practice for a good many years to sow sweet peas in the open ground in November, at the same time as we put in the first crop of edible peas. It is astonishing how much better they flower; and they are quite as hardy as the hardiest of the edible sorts. To keep up a succession, it is as well to sow again in February and the end of March. In this way, flowers of sweet peas may be had from June to November.—D. T. F.

The White Lily.

THE FLOWER GARDEN FOR FEBRUARY.

BY GEORGE WESTLAND, WITLEY COURT.

In re-arranging flower gardens, hardy evergreen shrubs may be employed with the best results; for in the working out of parterre patterns judiciously disposed groups with graceful outlines, associated with bedding plants, are more effective and desirable than many of the tender subjects now so freely used for such purposes, necessitating as they do the employment of unusual care and fertility of expedients on the part of the cultivator, and often, after all, producing but a small amount of success. One of the most important points in connection with flower garden operations at this season is preparation of the beds and the securing of proper composts; where beds are not planted with spring-flowering things, advantage should be taken of the fallow, so to speak, to which they are subjected to have them deeply worked up and prepared for planting. Upon poor soils, too little attention is often paid to our flower beds, which are kept under crop year after year without taking into consideration that the ground is becoming annually poorer. Flower-beds to be perfectly successful must be treated according to the crop which they are intended to carry. Some things, as for example, Abutilons, Aralias, Cannas, Ferdinandias, Ricinii, Solanums, Wigandias, &c., require a large amount of manure to give them nobility of aspect and perfect leaf development. In preparing beds for these, especially in cold, wet localities, it will be advantageous to place the soil on brick rubble, which will secure good drainage and tend to raise the temperature of the soil a few degrees higher than it otherwise would be. The compost should be used in rather a rough state in order to promote healthy development by gradual decomposition. Hardy Clematises grown as bedding-plants should now have attention; their blooming season may be considerably prolonged by pruning them at three different periods, viz., in autumn, mid-winter, and early in spring. Cut back to the ground, and surface-dress with rich rotten manure. This is especially necessary in order to insure continuity of bloom. Fill up all vacancies which may now occur among spring-blooming plants, and pay every attention to securing neatness and order. If the plan for the bedding out of the flower-garden has not yet been determined upon it should now receive immediate attention, in order that some idea may be formed as to what quantities of different subjects must be secured by means of propagation.

Shrubberies.—This is a good time to re-plant and re-arrange masses of the better kinds of rhododendrons, which, when grouped with taste, are gorgeous in the extreme. Their hardness and luxuriant deep green foliage render them desirable at all seasons; but many, nevertheless, are deterred from growing them from an impression that they do not succeed without peat. No doubt sandy peat is the best soil for them when procurable, but where it cannot be had they will not only grow but luxuriate in a sandy, fibry loam. The most satisfactory plantation of rhododendrons I ever made was one in a sandy loam skinned from an old wood six inches deep! In this the plants grew and flowered with the greatest freedom; and in the absence of good peat I can recommend this as the best material that can be substituted for it, not only for rhododendrons but for all kinds of American plants; it should, however, be rich in decayed vegetable matter. In preparing positions for rhododendrons resting upon calcareous matter it is imperative to success that the whole of the soil in the beds should be above the ground level, otherwise the drainage from the surrounding grounds will penetrate the beds and destroy the plants. In planting, hardy Azaleas must not be overlooked, their brilliancy of flower and delightful fragrance rendering them most desirable. They may be grown in masses by themselves or interspersed with rhododendrons, or used promiscuously in mixed shrubberies. Kalmias are not so much planted as they deserve to be, for they are amongst the most elegant of plants grown, their charmingly delicate blossoms and dark glossy foliage contrasting admirably with most kinds of vegetation with which they may be associated. They grow freely in low situations, and, moreover, the Kalmia is one of the few plants that game will not molest. Attend to previous directions as to planting and pruning. Common Laurels should be cut down, but under no circumstances should specimen Portugal Laurels be pruned now, as the scaring winds we often experience after this time, disfigure the foliage to such an extent as to render it unsightly for months, which late pruning will, in a great measure, obviate.

Pits and Frames.—As soon as plants in these are in a state to furnish cuttings, propagation may be proceeded with in a bottom heat of from 80° to 85°, and a growing temperature at about from 70° to 75°. Shade only to prevent flagging, and give ventilation as the state of the cuttings and other circumstances will admit. Accelerate, too, the growth of such plants as are required to produce cuttings, by placing them in heat. A sure and ready way of

securing a stock of Centaureas is to break out their growing crowns and to lighten the plants of foliage, placing them afterwards in a growing temperature, where free ventilation can be given to prevent "fogging off." Under such circumstances they make shoots quickly which, when fit for handling, should be slipped off with a heel and potted singly in the smallest sized pots; if plunged in bottom heat, they will speedily root and establish themselves. The variegated Polemonium should not be overlooked, and if cuttings are required, bring forward a few plants in heat, which will produce side shoots in abundance that will root freely. Abutilons, Cineraria acanthifolia, Ferdinandias, and Wigandias, &c., should now be incited to grow, pinching out their crowns so as to induce the production of side shoots for propagation. Variegated and flowering Pelargoniums, brought forward in heat, may now be propagated in soil consisting of loam, leaf-mould, and sand, in about equal parts. In the case of scarce sorts, of which the most should be made, take the cuttings progressively, choosing the strongest first. Where the stock of Alternantheras is insufficient, it should have timely attention as to propagation, as they are charming subjects for carpet bedding. The finest varieties are *A. amabilis*, *A. amabilis magnifica*, *A. amoena*, and *A. paronychoides*. A good companion plant for this style of bedding is the trailing Mesembryanthemum cordifolium var. *eratum*, which strikes freely and makes a lovely edging. Seeds should now be sown of *Acacia lophantha*, *Acanthus latifolius*, *Centaurea*, *Cineraria acanthifolia*, *Lobelia*, and *Camass*. The last, however, do not reproduce themselves true from seed, and therefore cannot be depended upon for anything but mixed arrangements. Keep up the heat in dung-frames by hot linings of stable-manure and leaves, and let out damp and steam by slightly raising the sashes. In cold frames, Calceolarias should be gone over, and stopped back; give air freely to such structures according to the state of the weather.

FAMOUS TREES.

THE MONKEY'S BREAD, OR BAOBAB TREE.

(ADANSONIA DIGITATA.)

THE Baobab is so gigantic in its growth, and appears to live to so great an age, that it has been justly considered one of the greatest marvels of the vegetable world. It was unknown to science till the French botanical traveller, Adanson, discovered it in Senegal, in the year 1749. Michael Adanson (of Scottish descent) was born at Aix, in Provence, in 1727, and was educated for the clerical profession. He had, indeed, already entered holy orders and obtained a Cure, when his original predilections for natural science, which had displayed themselves while he was yet a child, broke forth with such force that he quitted the Church as a vocation unsuited to what he felt to be his ruling instincts.

After studying the principles of botany with enthusiasm, and attending the lectures of Jussieu, Beaumar, and other great naturalists of the day, he set about preparing himself for an energetic career in the profound study of nature in all her various forms; and, as the first step, after the completion of his book studies, he determined to travel. Europe having been, as it were, thoroughly ransacked by the researches of former naturalists, he made up his mind to plunge boldly into Africa an untrodden field of scientific discovery; and having finally resolved upon this course of action, he confided his project to his father, and to their friend the Chevalier David, who was at that time chief governor of the French Compagnie des Indes. From this gentleman he obtained an appointment at the French factory (*comptoir*) on the Senegal, and, after having stayed some time on his route at the Canaries, Teneriffe, and Goree, he arrived in the Senegal River in December 1749, and found himself in reach of some of those vast districts of tropical Africa which had filled his imagination with enthusiastic longings.

He describes, in his "Voyage au Sénégal," his first impressions of tropical scenery with graphic power. "I experienced," he says, "an entirely new set of emotions, such as I had never felt before, at the new and strange appearances of nature which were presented to me. Earth, sky, plants, animals, the human race—all bore a strikingly novel aspect which at once riveted my attention and excited my utmost

THE BAOBAB TREE.

curiosity." In fact, he remained spell-bound during five years, discovering and collecting specimens of an almost endless series of wonderful natural products, entirely new to him as the first explorer of that region, and utterly unknown to modern science. It is true that vague reports had reached France, through ordinary and generally ignorant travellers, of vegetable wonders of an extraordinary character which were said to exist in the prolific region of the French possessions on the Senegal, especially rumours of enormous trees bearing gigantic fruit. But such stories were disbelieved in the scientific world, and contemptuously relegated to the domain of fable, from which it was supposed they had sprung.

Adanson was the first to verify some of the most extraordinary of these fascinating rumours, more especially that concerning the giant trees and their singular fruit. His description of this discovery is well worth repeating. At the village of Sor, not very distant from the mouth of the great river, he requested the natives, whose language he had made himself partially acquainted with, to conduct him to some part of the neighbouring forest where there was a good supply of game. After being taken some distance through the jungle, by a narrow path which in places passed through matted underwood, beneath which he was obliged to crawl on all fours, he came at last to a more open space, where he was delighted to behold a herd of beautiful antelopes; but he saw at the same moment another object which at once attracted all his attention, and in an instant the antelopes were forgotten. The object was one of the giant monkey-bread trees, an enormous Baobab. It was not the thing of fable which science had hastily supposed it to be, but a living, growing, wonderful entity. "Je ne crois pas," he exclaims, "qu'on ait rien vu de pareil dans aucune autre partie du monde." "How is it possible," he continues, "that it could remain undescribed by all those who have pretended to give us accounts of Sene-gal? The more especially," says the writer, "as I found it to be one of the commonest trees of that region." In his enthusiasm, he tells us, he at once attempted to measure the girth of the vegetable colossus by means of his fully extended arms. ("J'en fis le tour etendue les bras autant qu'il n'était possible.") He found that it required thirteen times their length to span the great trunk, and calculating the length of the measure thus used at five feet—he being a small man—the girth of the trunk proved to be, at a part as high as he could reach, sixty-five feet, giving a diameter of about twenty-two feet; dimensions which he afterwards found to be correct by means of a string which he borrowed from the negroes. The height of the tree was by no means extraordinary—he estimated it at not more than sixty feet; but its breadth was enormous. He found that the branches, which commenced at a height of about eighteen feet, extended each way full sixty feet before they touched the ground, giving a total breadth of one hundred and twenty feet; and each of these branches, with its lesser ramifications, would have formed, he says, a monstrous tree in any European forest. He afterwards found trees of seventy-six feet in girth and over twenty-five feet in diameter, apparently at the limit of their growth, which he believed to be extremely slow. The leaves of this vegetable giant are five-lobed, very large, and of a fine deep green. The flowers, which measure about eight inches across, are white, and crumpled at the edge, and somewhat resemble a large Hibiscus flower. The fruit is of gourd-like aspect, and about the size of a man's head. It consists of from ten to forty cells, containing several kidney-shaped seeds embedded in pulp. It is eatable, and has a sweet and not disagreeable flavour. The juice is used as a cooling drink in marsh fever, and is found generally useful in allaying feverish symptoms. The ashes of the wood are used by the natives, in conjunction with palm oil, to make a coarse kind of soap.

Adanson afterwards found, near Cape Verd many smaller Baobabs of about six feet in diameter, which, though still in the growing vigour of early youth, must be of great age, as measured by years; for he found carved deeply in their bark the names of some of the earliest explorers of the West Coast in the fourteenth and fifteenth centuries. This fact will give to these youthful Baobabs an age of about four centuries since the names were inscribed, at which time they must have been already trees of considerable size. From these data Adanson

reasonably enough assigns an age to the full-grown trees which stretches back far beyond the dim ages of our earliest historic records.

After his return to Europe the great botanical discoverer read to the Academie des Sciences a detailed description and character of the Baobab, which Cuvier has pronounced a masterpiece. In ingeniously arranged and minute detail the essay is exhaustive, and leaves nothing to desire. But one portion of the essay is hotly disputed by botanists, namely that referring to the age, which he assigns to the largest trees (as calculated by the concentric rings), which he estimates at over 6,000 years,* a period of time so stupendous, that the hesitation of the world of science to accept the calculation may be easily conceived. Yet, if the age of other less wonderful trees is calculated by the number of the concentric rings, and the result is not disputed, why may not the age of the Baobab be calculated, at all events approximately, on the same principle? But this is one of those discrepancies of science which may form the ground of many a good learned fight in the future.

H. N. H.

THE MONTEREY CYPRESS (CUPRESSUS MACROCARPA).—I did not say, as Mr. Barnes makes it appear (see page 220), that out of one thousand of this cypress planted near the sea, 999 died, and that one only was left. What I said was, that of the thousand referred to, "few now remained." The group of *Cupressus macrocarpa* to which I alluded was planted about fifteen years ago in well-prepared ground. The plants were about from two to three feet high, and were intermixed with a good assortment of other trees and shrubs, such as *Pinus austriaca*—which is still doing well—*rhododendrons*, *laurens*, *sweet bay*, *laurels*, &c., all of which acted as nurses. Thus situated, *Cupressus macrocarpa* grew away splendidly for a few years, until 1860-61; they were then about ten or twelve feet high, and the cold, cutting winds of that winter told upon them; they were swept and tossed about till the remnants look like so many broom sticks with the broom uppermost. Of the thousand planted, not a tree died in the first instance, because of the good ground in which they were planted and the good shelter which the other trees and shrubs afforded them. But directly they got beyond this shelter and outgrew it the severe winds were too much for them. For many years past I have been laying out private grounds and public parks, and the Monterey Cypress will always be found therein planted in considerable quantities, but not to "any required extent for shelter," and I repeat my caution as to the use of this cypress for that purpose. Mr. Barnes adds that he could "adduce proofs by the hundred" that *Cupressus macrocarpa* will thrive in an exposed situation. I should feel obliged if he will kindly point out some such localities, giving the number of trees planted, and when. That they will grow nicely for a few years I am well assured; but I am anxious above all things to ascertain where this cypress can be found in any quantity in this country, of, say, fifteen or twenty years' growth, and still showing the characteristics of a tree that we can plant with confidence for "shelter to any required extent."—W.M. BARRON, *Sketty*.

THE ARBORETUM FOR FEBRUARY.

BY JAMES BARNES.

MAKE all possible progress with trenching, planting, fencing, and draining. See to plants already planted; if blown on one side by the late winds, place them in an upright position; such as require stakes should be furnished with them when planted. Single trees in parks, paddocks, &c., not grown out of the reach of cattle, should have their guards repaired, if necessary, and new ones supplied where required. Pruning, thinning, faggotting, and clearing away of all wood, should be attended to for the next six weeks, where game is preserved, in order that there may be no interference or disturbance during the breeding season. It is often said that it is best to plant larch where pheasants are preserved, as they select that tree to roost on, which is true; but, in my opinion, lajoches are the worst of all trees for that purpose, as on them the birds are so fully exposed as to readily see, either by moon or starlight. Spruce firs are much safer trees, and have a nice appearance in the landscape. Seedling conifers and forest trees should now be transplanted on trenched land, and the seeds of last year prepared for sowing. *Picea nobilis*, which is one of the most lovely of coniferous trees at all seasons of the year, I have raised thousands from seed, and planted them out in various plantations and aspects, and a glorious appearance they are now making, and will continue to make, in the landscape, as they

* On the appearance of Adanson's paper, which is to be found in vol. 61 of the *Mémoires de l'Academie des Sciences*, attempts were made to calculate the age of the world by that of the Baobab.

attain age and size. Male catkins make their appearance in March, and female cones in May, the latter of a greyish blue colour. They increase in size quickly, and are full grown by midsummer, when they measure from eight to eleven or twelve inches in length, weighing down the branches. In September the seed gets ripe, which is indicated by extensive swelling, and a portion of a cone here and there bulging and cracking. If not then looked sharply after, they will very soon fall to pieces, and the seeds will get carried away by the wind. The seeds, which are the size of two barleycorns, are very full of turpentine. They should be sown the end of February or beginning of March on a healthy prepared border or quarter, patted firmly down, and covered with open sandy soil three-quarters of an inch deep. If a portion of charcoal is applied, so much the better. The same remarks with regard to the saving and sowing seeds of all *Piceas* hold good; for they all produce their cones in spring, and ripen their seed the same summer.

GARDEN DESTROYERS.

APHIDES: THEIR FRIENDS AND THEIR FOES.

BY EDWARD NEWMAN.

(Continued from page 212.)

THE enemies of aphides are quite as numerous as their friends, and quite as constant in their attentions. The principal—or I might say with greater precision, the better-ascertained—of these belong to four different classes: *Aphidius Rosea*, a minute Ichneumon belonging to the class Hymenoptera; *Syrphus Pyrastri*, hovering two-winged fly belonging to the class Diptera; *Chrysopa perlæ*, the golden-eye, a lace-winged fly belonging to the class Stegoptera; and, lastly, ladybirds, *Coccinella septem-punctata* and *Coccinella bipunctata*—these ladybirds belonging to the class Coleoptera.

The first of these, *Aphidius Rosea*, lays its eggs under the skin of the aphid, and out of the egg proceeds a grub which inhabits the body of the aphid and feeds on its living flesh, consuming the whole until the skin is left a dry husk. This insect parasitism is one of the most distressing phenomena in natural history: only meditate on the state of a living body being devoured, bit by bit, day by day, hour by hour, by a voracious indweller whenever hunger prompts him: only meditate on the fact of this horrible process being purposely and instinctively prolonged by the parasite's avoiding the vital parts, because the living flesh is the only food adapted to its requirements, and because if life once departed decomposition would set in, and the nutritive property of the flesh would be lost: so the victim drags on an enfeebled existence as long as its body has a particle of flesh for its ruthless destroyer to devour. This revolting history is familiar to entomologists; they know that thousands of these indwelling species exist, as if purposely to prevent the too rapid increase of the thousands of species that support them. It has been said that every vegetable-feeding species has a flesh-feeding species to hold it in check, and almost every vegetable-feeding individual contains in the recesses of its body, concealed from all observers, a flesh-feeding individual destined to take its life. The details of this particular instance of parasitism have been carefully observed and ably recorded by the late Mr. Haliday.

The male *Aphidius* may be seen throughout the summer, creeping about the rose leaves or running rapidly over the backs of a thickly packed phalanx of aphides, as if for amusement; his partner is of a less roving disposition, and confines her excursions to the straight path of maternal duty. Finding herself at birth amid the myriads of plant lice which encircle almost every shoot of the rose bush, she is content to remain there; she has no house to build, no stores of food to provide for her future offspring, no care to take of their education—if I may use that term for the exertions so constantly exhibited by mothers in the world of animals. She has only to lay her egg and leave it. With extended antennæ and iridescent wings shivering with desire, she walks sedately and leisurely over the aphid herd, and feels and fondles each with her antennæ until she finds one exactly suited to her purpose; then she stops short at about the length of her own body from the selected victim, and, standing erect on stiffened legs, she bends her abdomen under her breast until its extremity projects beyond her mouth; then, erecting her thorax by depressing the hinder part, she simultaneously makes a lunge forward with her abdomen, which is lengthened out in a most remarkable manner, and then by an instantaneous touch on the under-side of the aphid deposits a single egg. The victim of this treacherous and always fatal stab in the stomach will sometimes kick and plunge like a restive horse trying to throw its rider, but escape is impossible; the aphid is anchored to the rind of the twig or to the surface of the leaf by its sucker, which when once inserted is seldom withdrawn prior to the attack of the *Aphidius*. I advisedly use the word seldom,

admitting the possibility of withdrawing the sucker, for I have seen—who has not?—solitary aphides wandering slowly over leaves and flowers like sheep that have gone astray. Should the *Aphidius* meet with a luckless aphid thus nomadising, she will walk round and round it until a favourable opportunity occurs of taking it in flank, when the dead is done, the fatal stab given.

Mr. Haliday notices the extremely delicate sense of touch vested in the antennæ, which are always used by the *Aphidius* to obtain information whether an egg had previously been laid in an aphid, for one aphid could not support two *Aphidiæ*, and if two eggs were by accident laid in one aphid both the grubs must perish. There is therefore never more than a single egg laid in a single victim; the *Aphidius* ascertains by a touch how the case stands. We may call such knowledge instinctive, or intuitive, or empirical, just as we please—all that we know is, it is infallible; two eggs are never laid in the same individual.

When the parasite has consumed all the interior of its aphid, it may be found full and fat, a white maggot doubled up inside and filling out the skin of its victim, its head being placed nearest the tail of the aphid. When this period has arrived, the aphid withdraws its sucker, and, “like the stricken deer,” leaves the herd, and retires to die in solitude. It will then fasten itself by means of some gummy secretion to the upper surface of a leaf, and there remain, a helpless and hopeless picture of misery. The hardened skin of the aphid forms the only protection of the *Aphidius*, which spins no cocoon or other covering. A few days are sufficient for all its parts to acquire firmness and consistency; and, while the newly-risen sun is yet glittering in the early dewdrops, the now-perfected fly, by a gentle push, detaches two or three terminal segments of the aphid in the form of a lid, and comes out into open day, the separated segments springing back into place after the parasite has departed to make the first essay of his powers of flight, and to renew the circle of his existence. Sometimes a slight variation takes place in the programme, the detached and hardened case, instead of springing back to its place, hangs down like the lid of a tankard; and sometimes a circular hole in the back of the aphid shows where the life-robbler has escaped.

The second enemy of the aphid is the hovering fly to which entomologists have given the name of *Syrphus*. These will remain stationary, but not motionless, for many minutes, as though let down from heaven by an invisible thread, suspended like Mahomet's—but I forbear the comparison; it is worn threadbare. They appear motionless, but are not; their wings move with rapidity, that renders them invisible. Approach them or attempt to catch them, and they disappear, but return almost immediately, to hover again exactly in the same place, or perhaps a yard to the right or a yard to the left. This creature, while thus apparently doing nothing, is surveying the twigs and the leaves in search of a herd of aphides engaged in their life's business of sap-sucking. Having discovered a promising flock, she forthwith descends from her aerial perch and deposits an egg in their midst, leaving chance or nature to provide for its future. In fulness of time this egg becomes a grub of leech-like appearance, and wolf-like disposition. Even while still a baby, he exhibits his murderous propensities; he slays the lambs of the flock, and a rapid digestion enables him to dispose of these with great expedition. He soon attains his full stature, and all the while he is growing he lies lazily among his victims, who never exhibit the slightest fear of their dangerous companion, but continue sap-sucking with the most stolid indifference; or if they have occasion to move—and this is no common occurrence—they walk over his body without betraying the least symptom of distrust, and will even caress him with their antennæ. I believe these aphidions, for so they have been called, are totally blind. Kirby and Spence compare them to the Cyclops groping about for Ulysses and his companions; an apt comparison, for so does this creature, after fixing himself by the tail, feel about with his anterior extremity for his unresisting prey. His mouth is armed with a three-pronged fork, which he thrusts into the aphid up to the hilt, and then lifts high in air, the transfixed victim feebly and unavailing struggling to escape; in this strange position all its juices are extracted, and the empty skin falls on the surface of the leaf or drops to the ground. And these empty skins may be seen by dozens strewn around the scene of slaughter, and attesting in the most unmistakable manner the service which this strange-looking creature renders to the gardener, especially to the rose grower.

When this aphidion is full grown he glues himself to a rose leaf, or the leaf of any tree or shrub where he has been feasting on the plant lice; his body shortens and thickens, his skin becomes hard and firm, and after awhile he turns to a chrysalis, his own skin answering the purpose of a cocoon. A few days suffice for preparing him for the next and last transformation; the new parts—legs, wings, eyes—gradually assume consistency and form, his case-like skin bursts open, and he comes out more completely transformed than any of the subjects of Ovid's “Metamorphoses.”—*Field.*

GARDEN DESTROYERS IN FEBRUARY.

At this season of the year insect life is dormant or in abeyance, but a good deal may, notwithstanding, be done to prevent future mischief, and the gardener has the assurance that anything he does now is like nipping a disease in the bud, and probably is of many times the value of what he can do at a later period when his enemies, if more apparent, are more numerous and more rampant. In digging, he will meet occasionally with brown, long, barrel-shaped chrysalids in the earth from half an inch to an inch in length. These may safely treat as enemies. His friends do not assume this form in passing through the chrysalis stage, and he may find it worth his while to turn up with a fork the earth and moss at the roots of any trees in the neighbourhood of the garden in quest of chrysalids. Let him also search in outhouses and sheltered corners for those chrysalids which are not in the ground. We strongly advise the young gardener to put any he may find aside in a place where he can see them come out, not to make him an adept in entomology, although it would do him no harm to learn a little of that, too, but that he may learn at least the principal forms that come out of the different chrysalids. If he pins a sample or two neatly and puts them away in a box or drawer it will do him no harm, and he may rest assured that the knowledge he thus acquires will not be thrown away. There are always plenty of entomologists in towns who have not the gardener's opportunities, who would be only too glad to exchange information for specimens, and there is really no excuse nowadays for every gardener not being a bit of an entomologist. There is not a gardening periodical which has not entomologists of every kind and every degree—upon its staff or among its supporters, who are always happy to give information to every one who seeks it—and it is a kind of knowledge that pays the trouble of acquiring it by the wonderful ingenuity of the contrivances it disclosed and beauty it displays.

In the chinks of trees—especially fruit trees—many nascent evils now lie hid in the form of eggs, and in orchards where fruit suffers much from that kind of vermin this is the time to go over the branches with a nail-brush and Gishurst soap and water. There is a capital kind of nail-brush now made of fibres of palm (3d. each), strong and durable, which the gardener would do well to patronise, if not for his own, at least for what we may call the skin and nails of his trees, viz., the chinks in which the dust gets and the insects lay their eggs. This is the season in which, too, he ought to look over his fruit and other trees for indications of the various blights, and many a hidden foe may now be disclosed by cutting across a suspicious-looking twig or branchlet, when such disclosures as the beautiful yellow spotted caterpillar of the leopard moth, the large claret-coloured caterpillar of the goat moth, &c., may be met with resting in comfort in their wonderful tunnels.

A. M.

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

Soluble Sulphur.—I use this in spring in large quantities for the destruction of red spider on gooseberry and currant bushes, and prepare it as follows:—I slake some quicklime, and mix it with about half its weight of common flour of sulphur in a heap, with a little water, as in making mortar. After lying a few hours, I boil it for twenty minutes in a large boiler of water, in about the proportion of one gallon to one pound of the mixture. This produces a sulphurous liquid, about the colour of porter, two or three pints of which to a two-gallon bucket of water is strong enough for spraying; but we test the strength, by dipping a spray into the bucket, and get the liquor just strong enough not to damage the leaf. If too strong, the leaf withers in an hour or two.—R. VARDEN, Seaford Grange, Petersfield.

Chickens versus Insects.—We quote the following as conveying a hint which may be useful for other cases of insect damage, besides that of the Plum Curculio of America, to which it individually refers:—"For many years past," says an American paper, "the curculio has so sadly damaged our plum trees that they have had to be cut down as cumberers of the ground, no fruit being obtained from them." A writer in the *Ohio Farmer* says:—"I have a few nice trees still left standing for ornament and shade, and year after year these trees have bloomed and set full, but in spite of every effort until the present season not a quart of fruit was received. While the trees were in full bloom last spring, my wife determined to try an experiment upon one of them, which she did, and it resulted more favourably than could have been expected. Early every morning, while in bloom, corn-meal was strewn over the ground beneath the branches, and the whole flock from the poultry-yard at once set to work to gather up the particles of grain. The ground was daily thoroughly scratched over, and meal, insects, and everything to the fowls edible, gathered up. Later in the season, a brood of chicks were cooped beneath the tree, and the operation of strewing meal continued. This operation was not omitted for a day, from the time of the putting forth of the bloom until the plums were beyond the reach of the little pests. The result was that this tree, and this alone, was loaded with fruit as perfect as could be desired. So heavily, indeed, were the limbs laden, that props had to be used all around

the tree to keep them up. Not a plum matured on any other tree, and all are of the same variety as the one saved." The following from the *American Entomologist*, vol. ii., p. 53, is to the same effect:—"Having occasion to build a new house where a plum tree stood, instead of removing the tree, I enclosed the trunk, and trimmed off the branches to the roof. Result—I have for two years past gathered perfect fruit from the tree, and have not found one specimen stung by any insect. A temporary hen coop constructed under another plum tree the past season partially succeeded, while the trees not so protected lost all their fruit by the curculio." A very noteworthy circumstance to be kept in mind regard to such experiences as this is, that the plum curculio is winged in its perfect state, and both can and does fly, and yet there is no reason to doubt the accuracy of the facts above stated.

Wireworm.—I have had some experience on three-quarters of an acre of garden ground made from old turf land, and I feel sure the remedy which I adopted will answer the end on any land. The first and second years I was dreadfully pestered with wireworm; my potatoes, turnips, carrots, and other roots were pierced through and through with this pest. A thought struck me that the application of spent gas lime would settle my enemies; so I sent for two cartloads from the Dulwich Gas Works, and I had it mixed with six times as much good soil and manure, equal quantities; the manure was chiefly saved just upon which pigs had run. This was spread on the ground in November, and dug in a spade deep; then in the spring I put early and other potatoes and the general crop, with some light stable manure. I had excellent crops that year and afterwards, but not a single wireworm could I detect after that dressing. It is very important not to overload with the gas lime; dilute it well with soil and manure, and it will destroy grubs as well.—T. M., in "Field."

Insects in Winter.—One might suppose that by the end of winter little birds which are solely supported by insect food would find some difficulty in providing for their wants, but I have found the stomachs of the tree creeper and the small titmouse, even in February, quite filled with parts of coleopterous insects, which, by their activity and perseverance, they had been enabled to procure beneath the mosses, on the branches, and from the chinks in the bark of trees, where they had retired in autumn. Small slugs and some insects may be consumed by the severity of winter, but many of them are so constituted as to suffer no injury from the inclemency of the season, but afford during many months provender to other creatures.—*Journal of a Naturalist*.

Destruction of the Woolly, or American, Bug.—Among all the methods recommended for the destruction of the Woolly Bug, brushing, washing with essence of mint, turpentine, alcohol, soft soap, tobacco, potash, various oils, &c., we have found none to be perfectly effectual. We hasten, therefore, to communicate an "infallible remedy," which has been forwarded to us from several quarters. This is simply petroleum or paraffin oil. It is sufficient to brush the trees infested once with a paint-brush dipped in this oil (pure), applying it to all the parts attacked by the insect.

NORTH AND SOUTH.

The charts of the world which have been drawn up by modern science have thrown into a narrow space the expression of a vast amount of knowledge, but I have never yet seen any one pictorial enough to enable the spectator to imagine the kind of contrast in physical character which exists between Northern and Southern countries. We know the differences in detail, but we have not that broad glance and grasp which would enable us to feel them in their fulness. We know that gentians grow on the Alps, and olives on the Apennines; but we do not enough conceive for ourselves that variegated mosaic of the world's surface which a bird sees in its migration, that difference between the district of the gentian and of the olive which the stork and the swallow see far off, as they lean upon the sirocco wind. Let us, for a moment, try to raise ourselves even above the level of their flight, and imagine the Mediterranean lying beneath us like an irregular lake, and all its ancient promontories sleeping in the sun: here and there an angry spot of thunder, a grey stain of storm, moving upon the burning field; and here and there a fixed wreath of white volcano smoke, surrounded by its circle of ashes; but for the most part a great peacefulness of light, Syria and Greece, Italy and Spain, laid like pieces of a golden pavement into the sea-blue, chased, as we stoop nearer to them, with bossy beaten work of mountain chains, and glowing softly with tiered gardens, and flowers heavy with frankincense, mixed among masses of laurel and orange, and plumy palm, that abate with their grey-green shadows the burning of the marble rocks, and of the ledges of porphyry sloping under lucid sand. Then let us pass farther towards the north, until we see the orient colours change gradually into a vast belt of rainy green, where the pastures of Switzerland, and poplar valleys of France, and dark forests of the Danube and Carpathians stretch from the mouths of the Loire to those of the Volga, seen through clefs in grey swirls of rain-cloud and flaky veils of the mist of the brooks, spreading, low along the pasture lands; and then, farther north still, to see the earth heave into mighty masses of leaden rock and heathy moor, bordering with a broad waste of gloomy purple that belt of field and wood, and

splintering into irregular and grisly islands amidst the northern seas beaten by storm, and chilled by ice-drift, and tormented by furious pulses of contending tide, until the roots of the last forests fail from among the hill ravines, and the hunger of the north wind bites their peaks into barrenness; and, at last, the wall of ice, durable like iron, sets, deathlike, its white teeth against us out of the poplar twilight. And, having once traversed in thought this gradation of the zoned iris of the earth in all its material vastness, let us go down nearer to it, and watch the parallel change in the belt of animal life: the multitudes of swift and brilliant creatures that glance in the air and sea, or tread the sands of the southern zone; striped zebras and spotted leopards, glistening serpents, and birds arrayed in purple and scarlet. Let us contrast their delicacy and brilliancy of colour, and swiftness of motion, with the frost-cramped strength, and shaggy covering, and dusky plumage of the northern tribes; contrast the Arabian horse with the Shetland, the tiger and leopard with the wolf and bear, the antelope with the elk, the bird of paradise with the osprey; and then, submissively acknowledging the great laws by which the earth and all that it bears are ruled throughout their being, let us not condemn, but rejoice in the expression by man of his own rest in the statutes of the land that gave him birth. Let us watch him with reverence as he sets side by side the burning gems, and smooths with soft sculpture the jasper pillars, that are to reflect a ceaseless sunshine, and rise into a cloudless sky; but not with less reverence let us stand by him, when, with rough strength and hurried stroke, he smites an uncouth animation out of the rocks which he has torn from among the moss of the moorland, and heaves into the darkened air the pile of iron buttress and rugged wall, instinct with work of an imagination as wild and wayward as the northern sea; creations of ungainly shape and rigid limb, but full of wolfish life; fierce as the winds that beat, and changeable as the clouds that shade them.—John Ruskin.

THE KITCHEN GARDEN.

THE KITCHEN GARDEN FOR FEBRUARY.

BY JAMES BARNES.

KITCHEN GARDENING is now becoming interesting and, if well carried out, profitable. Everything should be planned and executed with foresight and method. Peas should now be sown on open quarters, ten, twelve, or fourteen feet apart, thus inducing them to produce as much again as thickly-sown crops. Planted or sown between the rows may be drills of early Turnips, Spinach, and Radishes, spring-sown young Cabbage, Cauliflowers, early Potatoes, &c., all of which will be off and out of the way by midsummer or sooner, rendering the ground available for Celery. After the Peas are cleared off, the space will be available for successions of Lettuce and Endive, young Coleworts, &c., all of which will be again off before the soil is required for earthing the Celery.

Asparagus.—Continue to get into moderate heat in succession, strong plants of this; let the bottom-heat be moderate and genial, in order to give it plenty of time to put forth strong, robust buds and shoots. Regulate the interior of the frame or pit by methodical airing. If the Asparagus is intended to be of a good flavour and eatable, allow it to colour well, by means of sun and air. Cover the roots lightly at first, then put on three or four inches, or from that to six inches, of well-decayed tan, leaf-mould, or light earth. Water early in the afternoon with tepid water, and shut up if intended to be bleached white. No glass need be used; shutters will do for cover, or it may be placed in a cellar or mushroom shed.

Broccoli coming on, keep a sharp eye on, and protect against frost by doubling the leaves down. Put a wisp of short straw over the heads.

Of Beans, plant this month a full general crop, such as Dwarf Gem, Early Long-pod, Broad Windsor, or any other good variety. Surface-stir on fine days, and dredge with dry dust against severe frosty nights.

Cabbages.—Surface-stir and make up all gaps and deficiencies. Make another planting from reserved transplanted beds, and sow a small quantity in pans or on a warm border. Prick out those sown last month into shallow boxes as soon as they can be handled. Place in shelter, harden off gradually, and prick on warm borders as soon as the season permits. For real usefulness, the small sweet kinds are the most profitable and best appreciated, large, coarse kinds being only fit for cattle.

Cauliflowers.—When well cultivated, this is one of the most valuable of our early spring and summer vegetables, requiring a little care and good culture. Sow small portions in succession, prick out those up in boxes and pans, and surface-stir. Plant out now some of the strongest autumn-sown plants that have been nursed and hardened in pots or frames on to warm borders. Surface-stir,

clear dead leaves, and harden off succession plants. Those nursed under hand-lights, encourage by surface-stirrings, drawing up all round a little earth in order to raise the glasses and form a basin in the centre for the application of manure-water.

Carrots.—Early varieties, such as Horn and Dutch, sow on well-prepared, healthy, warm, borders, in drills; and drill Radishes thinly between them for the last time this season. Shelter with straw or evergreen boughs for a time.

Celery.—Choose dry weather for applying earth to bleach late crops. Sow a pinch in gentle heat, and prick out early into shallow boxes or pans that sown last month to grow on in succession in frames, for early spring use.

Capsicums and Chilies sow in strong heat, and prick off as soon as up an inch apart in pots.

Chervil, curled, sow in small quantities in warm corners.

Lettuce.—Make good all winter crop blanks, and plant out in succession strong plants. Prick off and protect with dry dust small seedlings. Sow in gentle heat, and put a pinch on a healthy warm border, of summer Cos and Cabbage kinds. Beware of birds and mice.

Onions, autumn sown, transplant on well-prepared ground, a foot apart row from row, and six inches in the row, in order to have every other one pulled for early use. Sow in a box or frame, on a slight heat, Spanish, Tripoli, or any favourite variety, in order to have strong plants ready to put out the end of March or beginning of April. Sow thickly on a warm border and protect with a little straw the two-bladed union, for early drawing and "bulbing"; what is left, will be of a beautiful size, shape, and colour for pickling. Plant out Potato onions on firm ground; if on loose soil they are apt to canker, mildew, and rot. This also holds good in the case of Shallots, which should now also be planted above ground, that is, just pressed into firm soil. Garlic also plant now. Remove all old keeping onions into the coldest, draughty, dry place that can be found, in order to subdue growth and prevent exhaustion.

Parsley.—Sow the best curled in drills, one foot apart. Weed out from old beds or rows intended for seed every plant that is not fully up to the mark as regards curled quality.

Pcas.—Sow now some of the best varieties of second crop kinds, both dwarf and tall, such as Advancer, Auvergne, Green Marrow, Climax, Harrison's Glory, Perfection, Napoleon, Nonpareil, Veitch's Perfection, Champion of England, the Prince, &c. Shelter with sticks and a few green boughs in the cold windward side, and dredge with dry dust on dry evenings against frost those now up and growing.

Tomatoes.—Sow now; prick out, pot off into stiffish, poor soil, and harden off in due season those intended for outdoors.

Brussels Sprouts, Borecole, Budakale.—Sow the first portion after the middle of the month, in order to have some strong and fit to produce a heavy autumn and winter crop.

Turnips.—Early varieties, such as American Pink, Stone, Dutch, &c., sow on well-prepared warm borders.

Spinach.—Sow in single drills between peas, stir the surface soil about winter Spinach, which must be kept in a growing condition.

Place in gentle heat or shelter, successions of Tarragon, Mint, Sorrel, &c.

Seakale.—Keep up a good succession of this most appreciated vegetable by placing some on a gentle heat and covering with pots and fermenting materials crowns outdoors.

To Cucumbers in a bearing state keep up a kindly, uniform heat from 72° to 75°, charged with humidity; allowing, on nice, light, sunny days, a rise of 10°. Stop the shoots at every fruit joint. Put in cuttings of favourite kinds shy in the way of seeding. Sow in succession; make a kindly preparation of fermenting materials for those intended for outdoor frames. Do not allow those in fruit-producing order to carry too many at a time, to impoverish, weaken, and disease the vine; thus methodically.

Melons.—Plant out in succession on good holding, healthy soil. Sow now for full crop. Keep a good stock of healthy, sturdy plants in readiness for turning out as pits and frames become vacant. Do not allow overcrowding of the vines; stop seedlings first at third joint, after that at every joint showing fruit.

Potatoes now growing in pits, frames, or houses, under hoops, or other shelter, should have plenty of air to maintain sturdiness. Surface-stir those lately planted. Earth with moderately moist, lightish, healthy soil. Be careful about the application of water; never apply it overhead, but only to the soil. Never water early potatoes in the afternoon and shut them up directly, except you wish to produce disease; if by any accident they are caught in a shower when exposed to the air, leave them night air on and a space back and front of the lights for the moisture to have room to evaporate without settling on the foliage. A full crop of Potatoes should now be planted. Let them consist of early and middle early kinds, which have a better chance of escaping disease than late sorts.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

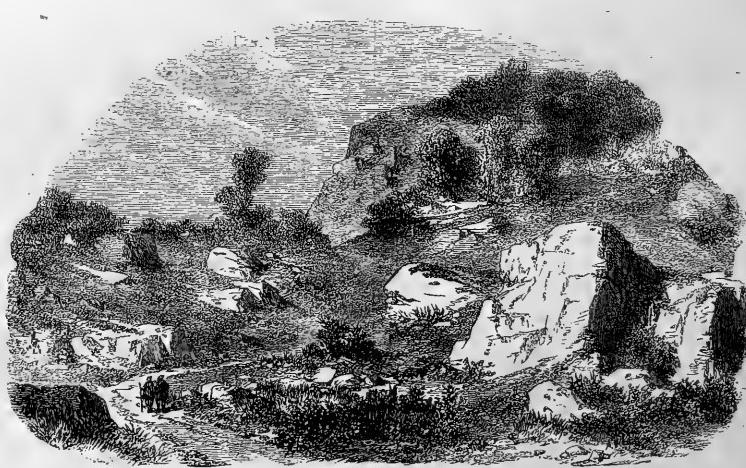

Miniature Mushroom Beds (see p. 207).—I was much interested by Mr. Fish's bold little mushroom-bed propositions in last week's GARDEN. The suggestion for the cook to grow his own mushrooms, by placing his sweet little beds on the kitchen-shelves and under the tables is admirable. It is cheerful, too, to contemplate Mr. or Madame Cook turning from the manipulation of pastry to that of the materials of which mushroom-beds are made, and vice versa. Permit me to add a thought or two to those of your correspondent: a few dozen miniature mushroom-beds would, for example, do nicely in quiet nooks, under our sofas, &c., and two might adorn the sides of each step in our broad staircases. Indeed, it would require a short catalogue to name all the places suitable for this fascinating kind of fungus culture. Why not fill some of the more roomy nooks in the sitting-room with the desired matrix, and have the pleasure of seeing the mushrooms grow under our very eyes? Best of all modes, however, for an imaginative horticultural writer would be to stuff his bolster with a miniature mushroom-bed, and allow the crop to grow forth at the ends. Vigorous mushrooms, however, would poke their heads through the linen. Will your talented correspondent try this, and let us know the result? And then some spring morning, when he opens his eyes, and finds the first half-dozen "buttons" inviting him to cut them for breakfast, I hope the spirit will again

GARDEN DESIGN.

GARDEN ROCKWORK GOOD AND BAD.

GARDEN ROCKWORK, if of a high and artistic kind, must be founded on natural models. The forms, the distribution of the masses, the accidental and divergent levels of the fractured face, as well as the forms, directions, and general character of the fissures, and every other feature of natural rocks, must be carefully studied before artificial garden rockwork, worthy of the name, can be attempted. A well-constructed piece of garden rockwork should be like the rockwork of a first-rate scene-painter—so excellent a device, that a young draughtsman might feel happy to transfer a memorandum of it to his sketch-book as a piece of art worth recollecting.

One of the most curious, and at the same time excellent pieces of artificial rockwork which I remember to have seen, is the work of medieval artists, the massive and yet highly-wrought work of Gothic chisels; and it has been sketched and painted and etched, over and over again, by travelling artists

Out-Cropping Rocks.

move him to encourage us to fresh attempts in this ever-interesting phase of gardening.—AGRIC.

Spawning Mushroom Beds.—Mushroom beds or boxes may be formed and spawned at any season, but decidedly the best times are in the months of September and February; for instance, a bed spawned in September will last through the winter months, and will be succeeded by the February or March bed, which will in its turn give a supply through the summer and early autumn.—B. W.

House Sewage.—Anyone who has a garden, and who wastes the slop-water and sewage from house and stables, wastes manure in a valuable form—this is certain. If to any country house there is a garden and land, all refuse, liquid and solid, should be used either on the garden or on the land. The distribution of sewage, or of any liquid manure, however, should not be by hose and jet; there are other special modes and means of delivering sewage and liquid manures for garden uses; the plants should know nothing of sewage but through the soil by their roots; the leaves should not be touched. I would not even hose and jet grass-land.—ROBERT RAWLINSON.

Broccoli.—London is now receiving large supplies of broccoli from Cornwall—last week about eighty tons; price from 1s. 2d. to 1s. 4d. per dozen heads. The crop is expected to prove a very good one. Bristol, Manchester, Liverpool, Leeds, Sheffield, and two or three other large markets are each receiving many tons weekly.

who have been wonder-struck on coming unexpectedly across this curiously elaborate piece of work. Branches of bramble, laden with berries, trail over it, and stems of ivy cling closely both to face and crevice; while small herbaceous plants fill the interstices with delicate leaf and blossom; and the wonder is that, the plant-work, like the rock itself, is entirely of stone; the whole, rock and plant, being equally the production of the ancient sculptor. These plants of stone are so truly wrought, distributed with such natural grace, thrown athwart the angular masses of rock (equally the work of the chisel) with such artistic boldness, that were they artificially coloured, like the exquisitely moulded plants of Della Robbia ware, they might be mistaken for the living originals, situated as they are in the open air, and first seen from a moderate distance. This singular piece of sculptured rocks and plants forms the entrance to the ancient tombs of the Emperors of Germany at the side of the Cathedral of Spires. It is well worthy the pilgrimage of every lover of art to look upon, and still more especially worthy the study of every would-be maker of artistic rockwork; as it shows plainly

with what patient labour every truly artistic result is attained, and at the same time that, without loving labour and loving thought, nothing great in art can be achieved.

Garden rockwork, however, even of the good kind, is a much more simple matter than the great sculptured mass at Spires. Yet, nevertheless, it cannot be effected without a good deal of trouble and considerable expense, if it is

Face of judiciously-covered, built-up Rockwork.

really intended to be of high character and on a large scale. Without a few bold masses of natural rock of considerable size, for instance, little can be done that is really grand, simple, and effective, and wearing that certain aspect of crispness and breadth which is always present in natural rocks. When such natural masses are not attainable, it is true that smaller pieces may be so built together as to present

Cavern.

the aspect of a continuous face with tolerable success; especially if the top line be well designed. But in such cases a careful design must first be made, and then carefully adhered to; the joints, when not natural-looking, being concealed as in the uppermost engraving. Some of them may be left as open crevices, in which great stars of sedum or masses of golden moss may cling; which, at certain points, may entirely conceal the

offensive joints. A mass of built-up rockwork may, after this manner, be managed with striking effect, if constructed after some good natural model, such as portions of the real rock scene at the commencement of these remarks.

Such is the best that can be done with built-up rockwork; but where large masses can be obtained, or where such crop up naturally out of the soil, the task is much easier, and almost invariably more successful. For instance, by breaking away certain portions, or by piling on others which may be broken off for that purpose, it is easy to produce a cavern, which, to a certain extent, is a purely natural one, and to all appearance entirely so. For instance, an effect similar to the cavern represented might be very easily contrived, and by the establishment of a few ferns and masses of wall Linaria in the crevices, a bold and entirely natural effect would be produced with little labour; the breadth of the naked unbroken surfaces imparting an air of unwrought simplicity analogous to the broad and bold workings of Nature's own hand.

In other somewhat similar cases, where natural rocks occur cropping out of the soil here and there, in suitable parts of the grounds for the creation of a display of rock-work, much may be done by excavation. In all probability, where one or two masses of rock project above the surface, other portions of the same formation occur at a short distance below it, and by judicious digging, following the sinuosities or suddenly irregular turns of the openings

Passage in Rock-garden.

between the masses, and, in some cases, by cutting a way through the stone itself, either in the form of a rude arch, or clear opening at the top, a rocky pass of very real and imposing character may be constructed. In one place it may be light and open, and in another dark and narrow, as shown in the woodcut. In rockwork of this nearly natural kind, it is sometimes difficult to arrange positions in which to establish plants of any considerable size just where they are desirable, and yet cannot be planted. In such cases seeds may be inserted into the smallest crevices with almost certain success; for plants coming up from seed will eventually take better care of themselves, and get a tighter and healthier hold, than things that have been transplanted, however skilfully.

Such are the best methods of producing really *good* rock-work. That which may emphatically be called bad, is generally formed by a heap of flints or glass-house clinker, which under the most favourable circumstances, and even when pretty well covered with creeping plants, produces no more satisfactory effect than that of a rubbish-heap which has been rather dexterously concealed. But when oyster-shells, fancifully disposed, or big lobster claws, or crab-shells, are used as adjuncts, it becomes at once evident that the constructor has not intended to conceal his rubbish-heap, but rather to make it very conspicuous, and we are compelled to wonder at his taste without being able to admire it.

The art of making really picturesque masses of artificial

rock is now so far advanced, as just described, that broad and good effects are produced in places devoid of a particle of natural rock. In numbers of places, however, there are grand rocks hidden or half hidden beneath the surface, which will with less trouble make more effective embellishments. The most remarkable results have been effected in this way in Mr. E. W. Cooke's peculiarly beautiful and interesting garden at Glen Andred, in Sussex.

H. N. H.

BLUE-FLOWERED HYDRANGEAS.

DURING a trip to Jersey last June we observed some magnificent blue Hydrangeas in the terrace gardens of the Royal Hotel. The colour of these was of the finest ultramarine, and wonderfully uniform. We remarked that among the blue-flowered plants there were others with rose-coloured flowers, but the plants which bore these were far less vigorous. The blue colour was always in direct proportion to the strength of the plant. The natural conclusion, therefore, was that the colouring agent also acted as a stimulating manure.

In 1857 Mr. Luscombe exhibited in London some splendid blue Hydrangeas. These had merely been planted in a small pine-wood, in the soil formed by the decomposed leaves of conifers. Now, up to that time, no one had thought that blue flowers could be produced in Hydrangeas, except by means of the following substances, and that, too, in different degrees:—Lime-water, water naturally impregnated with iron, common red sand, free Norwood soil, water in which hot iron had been dipped, alum in solution, iron filings mixed with the soil. To the presence of the iron in solution, of the lime, and of the alum, was attributed the effect of the various substances which we have just named. Now, Professor Solly proved by experiment that lime, alum, or iron, rendered more soluble by the use of hydrochloric acid, or less soluble by means of carbonate of soda, exercised only a moderate influence in the colouration of plants of the genus *Hydrangea*. On the other hand, Mr. Fortune, who could not produce blue Hydrangeas by the application of iron alone, succeeded in doing so by watering them with a solution of alum, or by applying this substance in powder. And yet neither peat soil nor leaf-mould contain any alum. We can only seek for the explanation of the effect of these soils in the tannin which they contain, and which is acted upon by the peroxide of iron which exists in the tissues of the shrub. This might be proved by making the experiment (which Dr. Lindley formerly suggested) of watering the plants first with water mixed with the peroxide of iron, and afterwards with a weak infusion of tannin. This is only one side of the question. In 1861 another Englishman brought forward the fact that blue-flowered Hydrangeas might be obtained by planting them in any soil which had never been previously tilled. He made several experiments with garden soil and virgin peat alternately, and obtained the same results for five consecutive years. Further, a specimen planted in cultivated garden soil, and producing rose-coloured flowers, began to bear blue flowers as soon as its roots reached the virgin soil which had been placed underneath the plant.

On the other hand, it is well known that in granitic, schistose, mica-schistose soils, and generally in soils of igneous formation, Hydrangeas bear blue flowers abundantly. Here the question rested; and the fresh experiments of M. Gris had thrown but little additional light upon it, when M. Eug. Fournier commenced some further investigations, after a discussion on the subject which had taken place before the Botanical Society of France. He watered some Hydrangeas with the following solutions daily, and in equal quantities, from the 1st of May:—

- 1st. 316 grains of ammoniacal alum to 1 7-10ths pint of distilled water (as recommended by Dr. Boisduval).
- 2nd. 316 grains of sulphate of iron (the common recipe).
- 3rd. 316 grains of carbonate of copper (suggested by M. Crochard).
- 4th. Ammonia (in no definite proportion).

By the 15th of June, the plants watered with the solutions of ammonia and the carbonate of copper had perished. Those which had been treated with the sulphate of iron exhibited a moderate degree of vigour and red sepals. The solution of

ammoniacal alum, on the contrary, had produced a luxuriant growth and large flowers of a violet-blue colour. From other experiments of M. Eug. Fournier, which we have not space to report here, the conclusion is that, if iron colours the flowers of *Hydrangea* blue under certain conditions, it is because it excites a more active growth in the same way as does ammoniacal alum. Beyond all doubt, the blue colour in the flowers of *Hydrangeas* is the result of an excess of vegetation artificially produced.

To these experiments we shall only add one observation, which is that, although we have seen in Jersey, and also in Guernsey, that the most vigorous *Hydrangeas* bore blue flowers, while the rest produced rose-coloured ones, we have also often found an exuberant growth of this plant coincident with the production of flowers purely rose-coloured. We need only mention, as an example, the *Hydrangea Otaksa*, which has been not many years introduced, and which is merely a Japanese variety of the common kind. At Versailles we have measured corymbs of it which were more than sixteen inches across, and which were exhibited by M. Duval, in May 1870.—*L'Illustration Horticole.*

Vegetation.—What infinite wonderfulness there is in this vegetation, considered, as indeed it is, the means by which the earth becomes the companion of man—his friend and his teacher! In the conditions which we have traced in its rocks, there could only be seen preparation for his existence; the characters which enable him to live on it safely, and to work with it easily—in all these it has been inanimate and passive; but vegetation is to it as an imperfect soul, given to meet the soul of man. The earth in its depths must remain dead and cold, incapable except of slow crystalline change; but at its surface, which human beings look upon and deal with, it ministers to them through a veil of strange intermediate being; which breathes, but has no voice; moves, but cannot leave its appointed place; passes through life without consciousness, to death without bitterness; wears the beauty of youth, without its passion; and declines to the weakness of age, without its regret. And in this mystery of intermediate being, entirely subordinate to us, with which we can deal as we choose, having just the greater power as we have the less responsibility for our treatment of the unfeeling creature, most of the pleasures which we need from the external world are gathered, and most of the lessons we need are written, all kinds of precious grace and teaching being united in this link between the Earth and Man; wonderful in universal adaptation to his need, desire, and discipline; God's daily preparation of the earth for him, with beautiful means of life. First, a carpet to make it soft for him; then, a coloured fantasy of embroidery thereon; then, tall spreading of foliage to shade him from sun-heat, and shade also the fallen rain, that it may not dry quickly back into the clouds, but stay to nourish the springs among the moss. Stout wood to bear this leafage: easily to be cut, yet tough and light, to make houses for him, or instruments (lance-shaft, or plough-handle, according to his temper); useless it had been, if harder; useless, if less fibrous; useless, if less elastic. Winter comes, and the shade of leafage falls away, to let the sun warm the earth; the strong boughs remain, breaking the strength of winter winds. The seeds which are to prolong the race, innumerable according to the need, are made beautiful and palatable, varied in infinitude of appeal to the fancy of man, or provision for his service: cold juice, or glowing spice, or balm, or incense, softening oil, preserving resin, medicine of styptic, refrigerant, or lulling charm; and all these presented in forms of endless change. Fragility or force, softness and strength, in all degrees and aspects; uncaring uprightness, as of temple pillars, or undivided wandering of feeble tendrils on the ground; mighty resistances of rigid arm and limb to the storms of ages, or wavings to and fro with faintest pulse of summer streamlet. Roots cleaving the strength of rock, or binding the transience of the sand; crests basking in sunshine of the desert, or hiding by dripping spring and lightless cave; foliage far tossing in entangled fields beneath every wave of ocean—clothing with variegated, everlasting films, the peaks of the trackless mountains, or ministering at cottage doors to every gentlest passion and simplest joy of humanity. Being thus prepared for us in all ways, and made beautiful, and good for food, and for building, and for instruments of our hands, this race of plants, deserving boundless affection and admiration from us, become, in proportion to their obtaining it, a nearly perfect test of our being in right temper of mind and way of life; so that no one can be far wrong in either who loves the trees enough, and every one is assuredly wrong in both, who does not love them, if his life has brought them in his way.—*Modern Painters.*

MOLE HUNTING IN GARDENS.

At a happy period of my life when I came into possession of the charming abode assigned to me, by the gracious favour of the Queen, in Richmond Park, I was discussing with the gardener, one fine evening in May, some horticultural operations, when a functionary of the Park was announced and made his appearance. He was the "mole-catcher," and had died his vocation there, he told me, man and boy for upwards of fifty years. He respectfully intimated to me that my predecessor had found it necessary to avail himself of his services in keeping down what would otherwise be a grievous pest to both lawn and flower-bed. I expressed my surprise at the intimation. Rats, I knew, were plentiful about, but moles I had thought were a scarce article in a garden. However, I inquired the "terms," as it was "in part of his regular business to look after the gentlemen's gardens belonging to the Park." My predecessor, it appeared, had subsidised the old expert at a guinea a-year, and I was warranted "never to see a mole twice" in the garden on these terms. The difficulty, it struck me, was as to getting any glimpse at all of the interesting burrower; but it was the mole-heaps old Warps meant; once levelled after the upturner had been trapped, they would not reappear. I hesitated, and pondered on the capabilities of my then limited salary from the Royal College of Surgeons, and its contrast with the probable fortune of my gallant predecessor at Sheen Lodge, and concluded that I must forego the luxury of keeping a mole-catcher.

Next morning I was disturbed at breakfast by my gardener, with the announcement that the moles had been at work; and, by a most curious coincidence in the very part of the kitchen garden where the conference with the mole-catcher had been held on the previous evening. There, sure enough, no fewer than six mole-hills had been raised in that very night, most of them breaking up the rows of the brightly-sprouting peas, on which I had been building flattering hopes of a rarely enjoyed luxury.

It seemed plain to me that moles and fresh-gathered peas were incompatible. I struck my flag: sent for the mole-trapper, and paid him his guinea in advance. I never regretted it. I got more mole-lore out of that old gentleman than I had ever before heard or read of. He always reminded me of a mole himself—a thin, prognathic visage, the nose longer than it was deep, and ending in a red point; the smallest, keenest eyes that ever peered out of sockets.

If at home on the evenings of his professional inspection, I usually ordered a jug of Mortlake ale into the arbour, and went in for mole-gossip. I owe to Warps my first evidence of the vocal powers of *Muscardinus vulgaris*. "You know, sir, these parts of the Park as the servant-galls and people won't go near to, after dark, coz of the screams of the murdered baby as was heard thereabout half the night." "Well, it must have taken a long time to kill," I interposed. "Now I tell you what that was, sir, it were a weasel as got trapped in one of my mole-traps, and I never heard a boast so loud afore. I couldn't 'a' thought such a little critter could 'a' made such a row."

After a long pull at the jug, old Warps grew confidential. "Now, I don't mind showing you, sir, what a mole can do!" And he pulled a live one out of the depths of a capacious pocket in his fustian jacket. "You'd never think to look at him he could run so quick!" And I own I was surprised the first time I witnessed the rate the little short-limbed animal sped along the hard ground till he came to the nearest bed, then with snout and the fore-shovels up flew the soft mould, and he was out of sight in a few seconds. "But, Warps," I exclaimed, "he's got into the carnation-bed, and will have them all up!" "Oh, never fear, sir! I'll have him again tomorrow;" and so he did. Whenever I wanted a mole for anatomical purposes, I had only to send to old Warps and it was forthcoming. No matter at what season, or of what sex, or in what stage of the "interesting condition" of the female. When other monographs now in hand are finished off, I may have leisure to work up my materials, so obtained, for an embryogeny of *Talpa europaea*.

I own to a voluntary blindness to one weakness of Warps, which I had not at first suspected, and to which some of my neighbours were less indulgent. I was making a call on the resident of one of those beautiful villas at Roehampton, just outside the Park wall, and was ushered into my friend's garden. We paced along the noble gravel-walk separated by a well-grown evergreen hedge from the park to the offices. Our chat happened to turn upon moles.

"Do you know," I asked, "how quickly they will run on hard gravel like this?" "Oh yes," said he; "I have seen it, and I can tell you more than that. Did you know, Professor, that a mole can leap?" "No," said I, "that it can't do; its organisation is quite unfit for that mode of motion." "It can, though," replied my

neighbour; "I have seen a mole take a flying leap over that very Portugal laurel" (it was at least eight feet high), "and come down on this very walk. It was then I first saw how fast a mole could run. Mr. So-and-So" (a common acquaintance) "happened to be here with me, and if he had not been quick enough to give the little beast a kick on the ribs before it had buried itself in the flower-bed, I should have believed it to have been a rat. Fancying I heard a footprint in the back walk just before the mole flew over the fence, I called my servant and asked if any one had been that way to the kitchen?" "Only old Warps," he said, "the mole-catcher." "Ah," rejoined my neighbour, "I suspected so. Tell that old rogue when next you see him, that if ever I catch him within fifty yards of my boundary, I'll make him remember it the longest day he has got to live!"

Poor old Warps was not far from his longest and last when he sent the live mole flying over the laurel bushes. About a month after he was laid in mother earth, where he rests quieter than his subjects.—Richard Owen, in "*Blackwood*," for February.

A WINTER GARDEN FOR LONDON.

"When we reflect," says a correspondent of the *Times* of Thursday last, "on the Siberian winter with which we were last year afflicted, and are led necessarily to anticipate something of the same sort for future seasons, we are lost in astonishment that in the whole *enceinte* of this great and magnificent metropolis there should not exist one establishment in which wholesome air and exercise, at a properly regulated temperature, can be obtained. Such a resource would be invaluable during the cruel winter months to those who fear to expose themselves to the chilling blasts of *Aëolus* and *Roraeas*.

"It was for a long time a question whether the transept of the beautiful Exhibition building of 1851, with its lovely fountains and gigantic trees, should not have been allowed to remain permanently on the spot where it stood, for the purpose of forming what is now so much desired, a winter garden. The clamour of a few interested individuals was allowed to overcome the desire of a numerous but unobtrusive public, to many of whom such a resort in the winter months would have been as life to death when compared with the confinement to the heated rooms of their own houses or an expatriation among the expensive inconveniences of a foreign sanatorium. It is really inconceivable that in rich and great London, where hundreds of thousands of pounds are constantly waiting for a profitable investment, no speculator should have thought of employing it in a manner sure to pay so enormously.

"Everybody knows that there was in Paris a few years ago a charming winter garden in the Champs Elysées, which was always kept at a temperature of 63° of Fahr., where hundreds took their daily walk who were afraid of exposure to the open air, for an entrance fee of one franc. It was a beautiful resort, filled with tropical plants, fountains, and all the little amusements for which the French are so famous—bagatelle tables, Chinese shows, shooting galleries, &c., affording pleasure as well as health.

"The writer of these remarks being subject to bronchitis, passed seven years in the immediate vicinity of that garden without having had one attack during that period, as he always had the resource on bad days of taking his exercise in its balmy walks, and he has frequently walked five miles on such occasions. This winter garden ceased to exist only because the demand for building ground became so great in that locality that it was sold at fabulous prices for erecting those palaces which border the Champs Elysées.

"Hundreds of ladies condemned to seclusion at home would drive to such a building every day to take their walks, and it would, without doubt, soon become a place of fashionable resort, as will be evident to everyone who remembers the familiar saying so much in vogue in 1851. 'Meet me at the fountain at five.' In order to the success of the speculation, two points must be kept in view:—First, the situation, which must be one of easy access to those who are best able to support the undertaking—namely, the inhabitants of the West End. The best site would be a small portion of Hyde Park, which her Majesty would not, I am persuaded, refuse. Next to the invalids themselves, the persons most interested in procuring and supporting such a building as this are the physicians of this metropolis, who, instead of finding their best patients deserting them in the month of October, to transfer their fees to foreign M.D.'s, would be enabled conscientiously to permit them to stay at home, and reap the benefit of their fees for their own pockets.

"At Pau during the late severe weather the thermometer stood as low as 17° of Fahr.; and at Arcachon the deluded hunters after southern, sunny climes were shivering in their wooden huts in a temperature of fifteen degrees below the freezing point."

SOCIETIES, EXHIBITIONS, ETC.

Royal Horticultural Society's Show at Birmingham.—The first meeting of the local committee was held on Thursday, the 25th of January, at the Great Western Hotel, under the presidency of the Marquis of Hertford. The hon. secretary (Mr. E. W. Badger), read the resolutions passed at the meeting on the 18th inst. He also read a letter from the Earl of Bradford, accepting the office of President of the committee, and requesting his name to be added to the list of contributors to the special prize fund for the sum of £25. It is intended, we believe, that there shall be a congress during the show week, the details of which will be published as soon as they have been decided upon. In the meantime, all who are willing to read papers, and take part in it, should at once communicate with the hon. secretary, *Midland Counties Herald* office, Birmingham, in order that arrangements may be made accordingly. In the case of those who wish to read papers, it is desirable that they should state the subject of them, and length of time they desire to occupy.

PRINCIPAL FLOWER SHOWS OF THE YEAR.

February.—14th.—Royal Horticultural Society (fortnightly meeting). 20th.—Manchester Botanical and Horticultural Society (monthly meeting).

March.—6th.—Royal Horticultural Society (fortnightly meeting). 13th.—Royal Botanic Society (spring flowers). 19th.—Manchester Botanical and Horticultural Society (monthly meeting). 20th.—Royal Horticultural Society (fortnightly meeting).

April.—3rd.—Royal Horticultural Society (fortnightly meeting). 6th.—Manchester Botanical and Horticultural Society (monthly meeting). 10th.—Royal Botanic Society (spring flowers). 17th.—Royal Horticultural Society (fortnightly meeting). 18th.—Royal Horticultural Society of Ireland (spring flowers). 23rd.—Cambridgeshire Horticultural Society (summer show). 23rd.—Royal Horticultural Society of Ireland (May show). 27th, to June 15th.—Royal Botanic Society (exhibition of American plants).

May.—1st.—Royal Horticultural Society (fortnightly meeting). 8th.—Royal Botanic Society (spring flowers). 11th.—Crystal Palace (great flower show). 15th and 16th.—Royal Horticultural Society (May show). 18th to 27th.—Manchester Botanical and Horticultural Society (grand national exhibition). 22nd and 23rd.—Royal Botanic Society (great summer exhibition). 23rd.—Cambridgeshire Horticultural Society (summer show). 23rd.—Royal Horticultural Society of Ireland (May show). 27th, to June 15th.—Royal Botanic Society (exhibition of American plants).

June.—5th, 6th, and 7th.—Royal Horticultural Society (great summer exhibition at South Kensington). 19th.—Ditto (fortnightly meeting). 19th and 20th.—Royal Botanic Society (great summer exhibition). 22nd.—Crystal Palace (annual rose show). 25th to 29th.—Royal Horticultural Society (great exhibition at Birmingham). 20th.—Bishop Stortford and Hertfordshire Horticultural Society (great summer show). 27th.—Royal Horticultural Society of Ireland (summer show).

July.—3rd.—Royal Horticultural Society (fortnightly meeting). 5th and 6th.—Manchester Botanical and Horticultural Society (roses and fruit). 10th and 11th.—Royal Botanic Society (great summer show). 17th.—Royal Horticultural Society (fortnightly meeting).

August.—4th.—Royal Horticultural Society of Ireland (autumn show). 7th.—Royal Horticultural Society (fortnightly meeting). 21st. Ditto (fortnightly meeting).

September.—4th.—Royal Horticultural Society (fortnightly meeting). 10th.—Manchester Botanical and Horticultural Society (monthly meeting). 18th.—Royal Horticultural Society (fortnightly meeting). 19th.—Cambridgeshire Horticultural Society (first autumn show).

October.—2nd.—Royal Horticultural Society (fortnightly meeting). 8th.—Manchester Botanical and Horticultural Society (monthly meeting). 10th.—Royal Horticultural Society of Ireland (great fruit show).

November.—6th.—Royal Horticultural Society (fortnightly meeting). 14th.—Cambridgeshire Horticultural Society (second autumn show). 19th.—Manchester Botanical and Horticultural Society (monthly meeting).

December.—4th.—Royal Horticultural Society (fortnightly meeting).

Cocoa-nut Groves.—The peninsula of Manabique presents the aspect of one vast grove of cocoa-palms, and affords the traveller an opportunity of seeing these trees in all their majestic beauty; rearing their tufted heads high into the air, while their roots are washed and often undermined by the rolling waves. No other tree ventures so near the water's edge, and dreary beyond description would this uninhabited coast appear, were it not for these littoral plants. The air is filled with a sort of music, produced by the wind, while shaking to and fro the long, sharp-edged leaves, and the wailing, doleful sounds thus brought forth cannot fail to impress the lonely traveller with melancholy thoughts or soothe his restless spirit. Thousands of coco-nuts annually fall into the sea; these, like the apples falling by the road-side, belong to the poor, or to those who take the trouble of picking them up. The coco-nut crop of the whole peninsula is annually sold by the authorities to some trading ship-captain, or to the highest bidder.—*Our Ocean Highways.*

OBITUARY.

M. R. THOMAS OSBORN.

The horticultural and botanical community has lost many of its prominent men of late—some, like Lindley, Hooker, and Paxton, ripe in years; others, like James Veitch and Berthold Seemann, in the prime of life; but not one that will be more regretted by all who knew him than Mr. Thomas Osborn, of Fulham, whose comparatively early and too sudden death it is now our painful duty to record. A principal of one of the oldest and most interesting of London nurseries, in him the commercial spirit was entirely subordinate to the love of plants for their own sake, and his knowledge of botany and horticulture was very great. What are called business' qualities were, however, developed in him in the highest sense, and led to his being appointed trustee of the Gardeners' Royal Benevolent Institution in the room of the late Mr. James Veitch, and to his co-operation being sought in the chief movements of the horticultural world, as, for example, the great exhibition of 1866. Possessed of wide and accurate knowledge of trees and plants of all kinds, and particularly of the harder and nobler subjects, the pleasure of a visit to the ever-interesting Fulham Nursery was always heightened by his cheerful guidance and great plant lore. He died at Fulham, of quinsy, on Sunday last. A day or two before his death, we had a communication from him respecting the weeping Sophora figured in *THE GARDEN* of January 20th, and of which there are two very old specimens in the Fulham Nursery, so rich in rare trees. To us, therefore, his loss has seemed peculiarly sudden, as he always seemed in robust health. Few men have adorned their profession more. No loss can be greater to the gardening community, and especially to London horticulturists.

COVENT GARDEN MARKET.—February 3rd.

Flowers.—These are now sufficiently numerous to give to the western entrance of the central avenue quite the appearance of a spring flower show. Little groups of lovely Tulips meet the eye on every side, supported by charming potfuls of Crocuses and Hyacinths. Then there are Callas, with their great trumpet-shaped white flowers; Spring Heaths; and Chinese Primroses, with blossoms large and richly-coloured. Cyclamens, too, with which everybody is delighted; Camellias and Azaleas; and last, but not least, pretty little bushes of Delphinium gracilis, loaded with blossoms that vie in purity with those of the Snowdrop itself. Among sweet-scented flowers are Lily of the Valley, Violets, Mignonette, and Wallflowers; and among berry-bearing plants, are different sorts of Solanum capicastrum, thickly covered with orange-red fruit, each as large as a good-sized marble. Other things consist of Acacias; Astilbe (*Spiraea*) japonica; Begonias; Christmas Roses; Cinerarias; Narcissus; Snowdrops; Frangipani hyacinths; Pelargoniums; Poinsettias; and Roses.

Prices of Fruit.—Apples, Dessert, 1s. to 3s. per dozen. Cobs, per 100 lbs, 6d. to 6s.—Filberts, per lb., 8d. to 10d.—Grapes, per lb., 4s. to 10s.—Lemons, per 100, 7s. to 10s.—Spanish Water Melons, each, 3s. to 5s.—Oranges, per 100, 6s. to 10s.—Pears, per dozen, 3s. to 8s.—Pine-apples, per lb., 4s. to 10s.—Pomegranates, each, 4d. to 8d.

Prices of Vegetables.—Artichokes, green, each, 6d. to 8d.—Asparagus, per 100, 8s. to 10s.—Beet, per dozen, 1s. to 2s.—Broccoli, purple per bundle, 10d. to 1s.—Brussels Sprouts, per half-sieve, 2s. to 3s.—Cabbages, per dozen, 10d. to 1s.—Cucumbers, per 100, 6d. to 2s.—Carrots, per bunch, 5d. to 7d.—Cauliflowers, per dozen, 2s. to 6s.—Celery, per bundle, 1s. to 2s.—Chillies, per 100, 18. 6d. to 2s.—Cucumbers, each, 1s. to 2s.—French Beans, new, per 100, 3s. to 4s.—Herbs, per bunch, 2d. to 4d.—Horse Radish, per bunch, 3s. to 6s.—Leeks, per bunch, 2d. to 4d.—Lettuces, per score, 1s. 6d. to 2s.—Mushrooms, per pottole, 1s. to 2s. 6d.—Onions, per bunch, 4d. to 9d.—Radishes, per bunch, 2d. to 2s.—Rhubarb, per bundle, 1s. 6d. to 2s.—Salsify, per bundle, 1s. 6d. to 2s. 6d.—Scorzonera, per bundle, 9d. to 1s. 6d.—Spinach, per punnet, 1s. 6d. to 2s. 6d.—Shalots, per lb., 8d.—Tomatoes, per bushel, 3s. to 4s.—Turnips, per small punnet, 9d. to 6d.—

Part I. of THE GARDEN, containing 6 Numbers and upwards of 80 Illustrations and Plans, may now be had, price 2s. Part II. is also now ready, price 1s. 5d., and may be had through all book-sellers and newsagents, and at the railway stalls.

Readers who may find it difficult to procure the numbers regularly through the newsagents or booksellers, may have them sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. THE GARDEN is sent to subscribers by Friday evening's post. All the back numbers of THE GARDEN may be obtained from the office, and through all booksellers and newsagents.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

GARDEN

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

Readers who may find it difficult to procure **THE GARDEN** regularly through the newsagents or booksellers, may have the numbers sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. **THE GARDEN** is sent to subscribers by Friday evening's post, to secure delivery in all parts of the country on Saturday. All the back numbers may be obtained through all booksellers and newsagents, and direct from the office.

THE FLOWER GARDEN.

ROSES AND ROSE CULTURE.

BY S. REYNOLDS HOLE.

ELECTING for beginners in rose growing a few varieties which are really winter proof, I find myself engaged in an enterprise which requires great nerve. I almost shut my eyes, and shiver at my own hardihood, as I pass over roses exquisite in beauty, but more or less delicate in constitution. I almost believe (for I am very superstitious about the sentient powers of plants)

that they feel a strong resentment, and that they go as far in opprobrious epithets as delicate ladies can with reference to my wretched taste; "I was in his forty-eight at Kensington;" "and I in his thirty-six at the Palace;" "and he made no end of a fuss about me at Birmingham;" methinks I hear them say; "and now we must give place to these coarse, vulgar wenches, just because, like tramps and gipsies, they've acquired the habit of living out-o'-doors in the winter."

And all this is harder to bear, because I am loyal and loving as ever to those who thus upbraid, and am only suggesting the harder varieties as harbingers and pioneers, knowing well that if the young rosarian is not discouraged and disappointed at first, he must have all roses beautiful, be they robust or sickly. But it's no good offering explanations, you know, to the feminine mind in a fume; and, therefore, let us on with our list.

From the son to the father, from John Hopper to his sire, Jules Margottin; the mamma being Madame Vidot. And as I write the name Jules Margottin, I am reminded to give a hint, *en passant*, not so much to new rose purchasers as to purchasers of new roses, always to buy the article which bears the maker's name—the rose called after its raiser.

As Mr. Ward named his glorious seedling after his friend (I have seen it referred to by the reporter to a London daily newspaper as "the John Hopper," under the impression, I suppose, that it took its title from some insect of the grasshopper family), so the French rosarians append to their best roses the appellation of persons or places dear to them (I will mention as examples, Jules Margottin, Victor Verdier, Mlle. Eugenie Verdier, Francois Lacharme, Marie Beaumann, &c.), and have given to second-best roses the names of first-rate English rosists, such as Thomas Rivers, Charles Turner, Madame W. Paul, John Keynes, &c., the only exception which occurs to my memory being the lovely Mrs. Rivers.

Jules Margottin should be one of the first roses ordered by the novice, hardy as handsome, and of the few perpetuums

which deserve the name, as being sure to bloom again in autumn.

La Ville de St. Denis is another constant and beautiful rose (quite good enough for exhibition in its best form), which, upon its own roots, has been in my garden for some twenty years. It withstood the fiercest ordeal through which roses have passed in my experience—the winter of 1860-61.

If Madame Boutin in the flesh resembles Madame Boutin in the flower, I offer my hearty congratulation to Monsieur as being of Benedicts Benedictissimus; for age cannot wither her; and be the seasons sunny or clouded, damp or dry, she is faithful and beautiful for ever.

To Mesdames Boll, and Caillat, and Clemence Joyneaux, and Domage, and Rivers, I must hurriedly pay a similar compliment, and then fly for my life, lest those inconstant beauties, Mesdames Furtado, Vidot, and many others, fascinating but frail, should fasten their thorns in my cheek. Whither shall I fly? From the boudoir to the barracks, to Maréchal Vaillant, the hero of a hundred rose fights? I know of no rose, unless it be Gloire de Dijon, which is more reliable than this. It never fails in my garden to produce abundantly its symmetrical rich crimson flowers.

And Marquise de Castellane will, I believe, prove to be hereafter as laudable for her generosity and endurance as she has already shown herself for her beauty.

Paul Neron is handsome, and strong as Hercules, and looks as though, in time, he could grow a stem which might make that demigod club.

I have the pleasure of knowing a goodly number of members of Parliament, but the one whom I most admire and believe in is pre-eminently Senator Vaisse. His rooted attachment to the land of his adoption, his faithful adhesion to his colours (his beautiful colours of crimson and scarlet!), his upright habit, his sweet beneficence in beautifying the homes of the poor, while he is equally welcome and gracious in his visits to the peer—all these good qualities are his; and I counsel those who do not know him to cultivate his friendship at once.

May they be more successful in cultivating the friendship of the rose than I was some years ago in an attempt to cultivate the friendship of a rosarian, whose name is borne by my last selection, Victor Verdier. I called upon him in the year 1861, and, supposing that he knew a little English, and that I knew a little French, I anticipated a gush of fraternal sympathy and sweet communion of kindred spirits. The gush did not take place. We could not understand each other in the least; and I do not suppose that two large men ever looked, or felt themselves to be, so small. I fled to my wife (I was on my wedding tour), and the Frenchman, I doubt not, betook himself to Madame Victor Verdier (her namesake is one of the most beautiful, but not one of the most hardy, of roses), and told her of his interview with a strange Englishman, gigantic in stature, but weak in intellect.

The Englishman has, nevertheless, sufficient intellect to admire the rose, though he failed to make himself intelligible to the rosarian; and he advises all young amateurs to include it in their first order. It is one of the grandest and most constant of roses.

I have only to append, in its completion, the little list of very hardy roses for beginners, to be planted immediately in soil well drained, and dry, and manured, away from trees, but not in a bleak, exposed position.—

Gloire de Dijon, Noisette	Comte de Nanteuil, do.	Madame Clemence Joigneaux, do.
Souvenir de la Malmaison	General Jacqueminot, do.	John Hopper, do.
Parbomber	John Margottin, do.	Mesdames Rivers, do.
Alfred Colomb, Hybrid	Jules Margottin, do.	Maréchal Vaillant, do.
Perpetual	La Ville de St. Denis, do.	Senateur Vaisse, do.
Baroness Rothschild, do.	Madame Boutin, do.	Victor Verdier, do.
Baronne Prévost, do.	Madame Boll, do.	Blairi No. 2, Hybrid China
Caroline de Sansales, do.	Madame Caillat, do.	Charles Lawson, Hybrid China

I omitted the last rose, when speaking of those which bloom only once; but he has pleaded with me for admission every time I have passed through my rose garden, reminding me how many years he has faithfully served me with large and beautiful roses, and at last convincing me that I should do an injustice to him, to myself, and to the young amateur, if I did not include him in my list.

CLIMBING DEVONIENSIS ROSE.

YOUR correspondent "D. T. F." says this is the tenderest of all tea roses; he also says it will not do upon a wall without being thatched over. Four years ago we planted, against a twelve-foot wall facing due east, a plant of the Climbing Devoniensis, budded upon a dwarf briar. The first season, owing to its having been cut rather closely for buds, it did not flower much; but the following spring it threw out one shoot eighteen feet long, with thickness in proportion, and several others of less dimensions. That season we had a few blooms which were very fine, but there were not many of them. Last season, however, the display was magnificent, as many as thirty beautifully-formed, half-open buds, with a quantity of others in various stages of development, being all visible at one time—the admiration of all who saw them. This tree withstood the severity of the winter of 1870-1871 without being in any way injured. It was neither thatched nor protected in any shape. Against the same wall we have, on three successive seasons, lost plants of Maréchal Niel, on the Manetti stock. We have also standards of Climbing Devoniensis, which did well last winter, planted upon a piece of ground facing due north; but we cannot say as much for several other teas planted in the same situation, such as Madame Falcot, Madame Margotin, Madame Willermoz, and others, all of which have been cut down to the buds. C. W.

White Cross Nurseries, Hereford.

A HEREFORDSHIRE COTTAGE GARDEN.

A PLEASANT garden, with plenty of large and fine pansies, some roses, and great promise of more. It is extremely neat, clean and finely kept, and it is the pride of the mistress that she takes the entire care of it herself; as we walk, she has her scissors in her hand, and cuts flowers; and when we are seated in a curious little arbour of clipped yew, where she had left her "work" when she came in to see us, she arranges nosegays and presents them to us. The house is small; the walls are of plain red brick; the roof of slate, with but moderate pitch; the chimneys and windows of the usual simple American country-house form and size. There is no porch, verandah, gable or dormer, upon the garden side, yet the house has a very pleasing and tasteful aspect, and does not at all disfigure the lovely landscape of distant woody hills, against which we see it. Five shillings' worth of material from a nursery, half-a-day's labour of a man, and some recreative work of our fair and healthy hostess' own hands, have done it vastly better than a carpenter or mason could at a thousand times the cost. Three large evergreen trees have grown near the end of the house, so that instead of the plain, straight, ugly red corner, you see a beautiful, irregular, natural, tufty tower of verdure; myrtle and jessamine clamber gracefully upon a slight trellis of laths over the door; roses are trained up about one of the lower windows, honeysuckle about another, while all the others, above and below, are deeply draped and festooned with the ivy, which, starting from a few slips thrust one day into the soil by the mistress, near the corner opposite the evergreens, has already covered two-thirds of the bare brick wall on this side, found its way over the top of the tall yew-hedge, round the corner, climbed the gable-end, and is now creeping along the ridge-pole and up the kitchen chimney—which, before speaking only of boiled bacon and potatoes, now suggests happy holly-hangings of the fireside and grateful harvest's home, hides all the formal lines and angles, breaks all the stiff rules of art, dances lightly over the grave precision of human handiwork, softens, shades, and shelters all under a gorgeous vesture of Heaven's own weaving.—*Olmsted's Walks of an American Farmer in England.*

A NEW GRASS (ERIANTHUS MOUSTIERII).

THE plant to which we have given this name, in remembrance of its introducer, M. le Comte A. de Moustier, is not only new, but probably unknown in Europe. It is a native of Mount Olympus, near the town of Broussa, where M. de Moustier met with it growing amongst shrubs, in a perfectly wild locality, during his journey through Asia Minor about the year 1861. These details are authentic, having been furnished by M. Vilcet, gardener to M. le Comte de Moustier, at La Chapelle-sur-Creey (Seine-et-Marne), in a letter which he wrote to us November 22, 1871, and from which we extract the following:—

"This species grows much taller than our tallest *Gynuriums*. M. de Moustier, when gathering the seeds, was obliged to stand upright in his stirrups, being on horseback at the time. The stems which sent me were almost as white as those of the *Gynurium*, but not nearly so strong; they were very silky and flexible."

"I sowed the seeds in March 1863 in a seed-pan, which I placed in a temperate house; they began to vegetate in about a month's time. At this stage of their growth the plants were so like *Gynuriums* that, but for their label, I should hardly have been able to know the difference. About May I potted them off into three-inch pots, and then successively into six-inch and ten-inch pots. During the winter of 1863-64 I put them in a temperate house, where they remained until May 1864, when I planted them out in the open air. It was only then that I perceived that the leaves had a white stripe running down the centre. At the present date the only two plants which I have left stand on a shady knoll; they have as yet given no signs of flowering."

Having ourselves possessed this plant for two years (M. le Comte de Moustier having had the kindness to send us a strong specimen in the spring of 1869), we are enabled to describe it:—It is a cespitose plant, not running at the root, but with a very stout rhizome, from which issue numerous closely-set shoots. The leaves are very long, comparatively narrow (almost rushlike), very flexible, arching forwards in a graceful curve, and having in the centre a prominent rounded midrib, the top of which is concave and marked with a white line; the edges of the leaves are very finely toothed, but do not cut like those of *Gynurium*; the underside (and particularly the leaf-stalk) is covered with white silky hairs. From the centre of the principal leaf-stalks issues a jointed flower-stem, sheathed for a great part of its length by the enveloping and villose base of the leaves. This flower-stem attains a height of nearly ten feet or even more, and bears the inflorescence at its summit.

We are not certain that this plant belongs to the genus *Erianthus*. If we have placed it there, it is because of its resemblance to that genus, of which it appears to possess all the characteristics. But even if it should hereafter have to be transferred to the allied genus *Saccharum*, it should still be allowed to retain the appellative *Moustierii*, in memory of its introducer the Count de Moustier.—*Ed. Carrière, in "Revue Horticole,"*

NOTES ON BEDDING PLANTS.

LOBELIA SPECIOSA.—Many raise their stock of this from seed sown in heat in spring; but a much better plan is to sow it in October. Our seedlings of it, sown last October, and placed on a shelf near the glass in a cool house, are now strong and healthy, and ready to prick off; when established, they will be moved to a cold pit. There is no comparison between dwarf, bushy, autumn-sown plants of this *Lobelia* and those raised in heat in spring. When the stock is kept true, and carefully selected, seedlings will generally hold their own against cuttings. Nevertheless, with particular kinds, and for certain positions, we always raise a part of our stock from cuttings.

LOBELIA FUMILA GRANDIFLORA.—This has a dense dwarf habit and bright blue colour. Planted rather closely, I have no hesitation in saying that it makes a very beautiful bed.

SPOTTED DEAD-NETTLE (LAMÍUM MACULATUM).—Without seeing this in a mass, it is impossible to form an opinion as to its beauty and usefulness in the flower-garden. Either for winter, spring, or summer decoration, it always looks fresh. It does beautifully for covering the edges of raised beds, or for forming undergrowth in beds of *Dracmas* and similar plants. It is, also, especially useful for softening and toning down bright colours.

ABUTILON THOMPSONII.—This beautiful variegated greenhouse plant is a great acquisition in the flower garden, either for massing, or as single specimens, or in mixed beds of foliage plants, or as a front plant in an ornamental shrubbery. It will bear several degrees of frost without injury, and, if carefully lifted in autumn, and potted, it will be found useful in the conservatory. We have several plants of it which were potted up from the borders last autumn that have been in flower ever since, and that will continue in that condition through the winter. Young shoots strike freely in spring in a hot-bed.

ACER NEGUNDO VARIEGATUM.—All who have seen this beautiful Maple in Battersea Park will require no further inducement to plant it. Dwarf plants of it make a striking bed; standards or half standards succeed beautifully, and look well in the centres of large beds. They have, also, a fine appearance in shrubberies, brightening up, as they do, in an astonishing degree dark masses of evergreens in summer.

CENTAUREA RAGUSINA.—This, I need scarcely say, is one of the best and most useful white-leaved plants for the flower garden yet introduced, and it is easily propagated in a cold pit in September. Last autumn, after our September stock was in, we found that we required nearly a thousand more cuttings. These were put in the first week in November, and from them we shall obtain, at least, nine hundred plants. Anyone, too, who has a few old plants may easily increase them in the spring in this way: cut off the soft growth down to where the shoots are rather firm; place the plants near the glass, in a temperature of 55°; plenty of young shoots will soon push from the stems; and when an inch or an inch and half long, will strike in a hot-bed as easily as verbenas, and make nice plants by May.

E. HODAY, *Ramsey Abbey*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Perpetual Red or Pink Climbing Roses.—May I ask Mr. Reynolds Hole to be kind enough to furnish me with the names of eight or ten good red or pink climbing roses, for either the wall of a house or for a veranda? I have twelve columns of a veranda, on which I wish to plant alternate colours of roses. Of the yellow, white, &c., there can be no want; but the difficulty is in finding good sorts of perpetual red roses for either pillars or walls. I may mention that it is for a place in Kent, with a dry, sandy soil.—**CONSTANT SUBSCRIBER.**—“To the above Mr. Hole has kindly furnished the following reply:—‘I grieve to inform your correspondent that climbing roses in bloom perpetual, and in colour red or pink, are hopes, but not realities, to us rosarians. They are visions of beauty which we see through our rose-coloured spectacles, to be verified hereafter, as I firmly believe, to those organs which Mr. Weller has described as ‘our worry eyes.’ In kindly soil General Jacquemint and Climbing Giant des Batailles would, I think, satisfy your correspondent’s requirements, and there is a Climbing Victor Verdier, raised by Mr. George Paul, of Cheshunt, which seemed to me full of promise; but I know of no other red or pink perpetual climber, which can enlarge this trio into a quartet. There are reliable varieties which flower but once, such as the Crimson Boursault and several of the Hybrid Bourbon and Hybrid China families; but these are not what your correspondent wants.’”

The Rose-Tree of Hildesheim.—The oldest rose-tree known is said to be that which covers a wall of the Cathedral of Hildesheim, in Germany. It is a thousand years old. From the main stem, which is a foot in diameter, extend six branches, fifteen feet high. In the Middle Ages it was afforded a shed roof, as a protection from the vicissitudes of the weather.

Cheap Roses.—“Y.” (p. 204) says we can have roses at threepence each. One can hardly manage them for that at home—I mean standards—though we have learned the art of buying the briars in the cheapest market, and growing and working them in a wholesale way in out-of-the-way places. I confess I have never been very successful, except with Teas, Chinas, &c., and it is rather galling to one who likes dwarf roses best of all on their own roots to throw away thousands of shoots of Perpetuals every winter, if they really can be made to strike like willows, under certain treatment. Will “Y.” kindly inform us what this treatment is? for I see no prospect of roses at 3s. per dozen, unless we strike and grow our own. Neither will this hurt the growers, for all must go to them for new varieties, and new rose growers by the thousand are cropping up afresh every year. It is, too, a most extraordinary fact that the more roses we work, the more we buy.—D. T. F.—[Other correspondents write for information on this subject. “Y.” says he does not like to part with his secret.]

Vervenas for Bedding Purposes.—Will you kindly name a few good varieties suitable for beds?—K. J.—[Mr. Westland says the best bedding verbena, taking habit and continuity of bloom into consideration, are Aristo Improved, rich mulberry; Crimson King, a compact and good bedder; La Grande Boule de Neige, a fine white; Purple King, the best purple; Perfection, pink; Venosa, a hardy variety, producing a charming effect when planted in masses or grouped, coming true from seed; Celestial Blue, a good and distinct sort; Firefly, very bright scarlet; Melindris splendens, vivid scarlet, well adapted to form a ground work for other plants, very desirable; Snowflake, white; Annie, rosy pink, striped with white; and Blondin, magenta, very compact.]

Santolina incana.—This has proved a good acquisition to our flower gardens in summer; it is perfectly hardy, forms a neat edging plant for beds or borders, and is equally valuable for carpet-bedding purposes. It never exceeds nine inches in height; if required it can be pinched down to within one inch of the ground; it will stand three or four years. As soon as the flowers appear in spring, clip it down to the required height; it will soon recover and assume its beautiful silver appearance. The best method of propagating the Santolina is to lift a few plants in autumn, cut them close down and pot them; store away in a cold pit or frame, and remove them, say about the beginning of February, to a propagating pit or house. As soon as the young growths have attained an inch in length, take the cuttings off; guard against injuring the cuttings, a sharp knife being essential to prepare them; insert them in pots or pans, prepared in precisely the same manner as for verbenae cuttings. It is a waste of labour to attempt to strike the Santolina in pots in autumn; then they will strike inserted in a shady situation in the open ground. They ought to be hardened off by the beginning of May, when they may be taken from the store pots, and planted out about four inches apart; they will form a beautiful edge, and amply reward the cultivator for any trouble bestowed upon them. This Santolina is also a neat and attractive rock-plant.—*H. W., Bury St. Edmunds.*

Bambusa edulis.—Of the numerous species of bamboos which are hardy in our gardens, and which have been introduced within the last ten years from China, Cochin China, and other regions of the distant East, none has exhibited a more vigorous growth than *Bambusa edulis*. We have seen it produce in two years shoots over nine feet long, and as thick as a man’s wrist at the base. These giant pseudo-araceae did not begin to branch until they had reached their full length. One might “see them grow,” as the gardeners say. We have not yet tried to eat the young shoots, which are said to be nutritious, and we are now only urging the ornamental value of this fine plant in moist soils and on the margin of pieces of water.—*Ed. André, in L’Illustration Horticole.*

GARDEN DESTROYERS.

APHIDES: THEIR FRIENDS AND THEIR FOES.
BY EDWARD NEWMAN.

(Continued from page 243.)

A WORD must be said about the “golden-eyes,” the “lace-winged flies,” whose larvae are also called aphishions, and well deserve the name, for they spend the whole of their existence—I mean the whole of the larval portion of their existence—in gorging themselves with aphides. In many particulars of their lives the two kinds of aphides resemble each other, but in others they are decidedly different. The golden-eyes fly in the evening only, unless disturbed; the Syrphi fly only in the sunshine, or at any rate in the hottest and brightest hours of the day. Then the mode of flight is different; the golden-eyes have a very uniform fluttering, and feeble flight, and never suspend themselves seemingly motionless in mid air, or dart off with lightning speed, as do the Syrphi. Their mode of egg-laying is essentially different; seven or eight eggs constitute the whole of one laying. I have seen ten in one instance, but this is very unusual. Almost every entomologist with whom I am acquainted has described these eggs as attached to the disk or surface of the leaf, but I have commonly found them attached to the edges. The female stands on the edge of the leaf, and with the tip of her body just touches it, emitting at the same time a small quantity of liquid glue. Then, still holding the leaf with her legs, she draws her body away from the leaf, at the same time discharging this liquid glue in the form of a hair, which almost immediately hardens, assuming the appearance of a real hair; at the extremity of this seeming hair, which does not usually exceed half an inch in length, she leaves a long oval egg; she repeats the same process with a second, third, and so on, up to seven or eight. The eggs thus deposited have a most singular appearance. When the inclosed larva is ready for exclusion, he pushes off the top of the egg, and pops out his head like Jack-in-the-Box. He then comes deliberately down the seeming hair which supports the egg, and at once finds himself surrounded by his living food. But I must dwell for a moment on the empty egg-shell, which is a most beautiful object. It resembles a hair-ball on its long footstalk, or still more nearly those pretty campanulate aquatic zoophytes which our microscopists delight to contemplate, and our natural history artists to portray.

When full fed, the larva leaves the scene of slaughter, and retires to a neighbouring crack or other place of concealment, and there spins a little round cocoon, so very small that it is difficult to conceive how it can hold the large lace-winged fly which has to come out of it. There is so great a discrepancy between the size of the cocoon and the fly that I could not for a long while trust the evidence of my own eyes, and thought I must have made some mistake, but repeated observation convinced me I was right. There is something equally strange about the fabrication of this cocoon. It is spun not from a silken thread proceeding from the mouth, but from silk produced at the other end of the body. This strange creature is furnished with little nipple-like warts, very small, and quite invisible to the naked eye, situated just where we observe the spinnerets of a spider, and from these issues the silk necessary for constructing the pea-like cocoon in which the creature chooses to imprison itself. And here I cannot resist the temptation to invite the attention of naturalists to the almost exact accordance of these spider-like larvae of aphishes, and antlions as well, with the true spiders in their full grown and adult condition. The food is exactly the same, the mode of seizing it with the jaws the same, the mode of extracting its juices for nutriment the same, the absence of all mastication the same, the consequent rejection of all the solid parts the same, the mode of producing silk from the extremity of its body the same, and finally the cocoon of the golden-eye so exactly resembles the egg bag of a spider that, with fifty years’ experience, I am even now unable to distinguish some of them without opening; but then the resemblance is at an end—the spider’s cocoon contains eggs; that of the aphision contains itself, and nothing more.

With regard to the perfect golden-eye, a few words may suffice to describe it. It has two eyes of the most glorious gold-colour—indeed, more golden than the precious metal itself—no burnished gold can compare with the beauty and lustre of these eyes. Several entomologists have tried to account for the extraordinary beauty of these eyes by the presence of a peculiar varnish which is spread all over them, and say that this varnish catches the light in some peculiar manner, and thus acquires its intense brilliancy; but this is purely imaginary, and we can only admire without explaining. The wings are four in number, beautifully reticulated and exactly alike, and the body and legs are green. Altogether it is one of the most attractive-looking insects that our gardens produce; but the attraction lessens when you handle it. Catch it, and hold it for

examination between your finger and thumb, and it will emit a stench so intolerable that you are glad to release it instantly, and wash your hands to rid yourself of the contamination.

What shall I say of the ladybirds? We know that they are the favourites of children, who delight to pick them off the leaves by the wayside, to let them crawl up to the tips of their fingers, to watch them open their coral wing-cases, spread their gauzy wings, and launch themselves on the summer air. The little ones will then advise their pets to return to their homes, on account of a domestic calamity, a conflagration, to which it is necessary they should attend at once, because their children are still under the paternal roof, which is becoming a prey to the devouring element. We know also that they are the most serviceable of insects, and seem, like the Aphidii and the aphishins, to have been expressly created by an Allwise Ruler to hold in check the aphides, those scourges of farm and garden against which man, with all his power and all his experience, is utterly defenceless. All this we know, but very little more. I will relate a little, a very little, of their life-history.

The female, wandering over the aphides, and making a meal of two or three, as her inclination prompts—hunger is out of the question with such an abundant table spread before her as the succulent shoot of a rose bush smothered with a serried phalanx of aphides—will now and then pause from a feeling of repulsion, and lay a few yellow eggs wherever she can introduce her ovipositor among her victims. These hatch, and produce little hexaped, lizard-like larvae, and these, being born amidst their food, begin killing and eating in their very babyhood, and continue killing and eating until arrived at their full stature, when they fix themselves by the tail end of their body to the surface of the leaf; and, after a time, sundry movements show that, although thus securely moored, a locomotive instinct is at work within. This exhibits itself more and more decidedly until the skin parts at the head end, is gradually shuffled downwards towards the other extremity, and remains just round the tail, pucker'd and fold'd like a stocking pushed down to the ankle and left there, the foot still remaining covered. The object that has thus wriggled itself out of its skin, or almost out of its skin, is a chrysalis of very curious form; its head is bent under its breast, its back is rounded or humped, and notched like a saw, and the two wing cases, or what are destined to become the wing cases, hang down beneath the body like the flippers of a seal. They do not touch any part of the back, which in a few days they are destined completely to cover and protect; as a thatched roof covers and protects a cottage, overhanging it all round. This chrysalis exhibits an impatient, angry disposition if you touch it, and jerks itself from side to side in futile efforts to escape, which is rendered impossible by the secure manner in which the creature has fastened itself by the tail. The chrysalis state lasts ten or twelve days, and then the perfected ladybird emerges, clothed in black-spotted scarlet. In this state, like the golden-eye, it has the power of emitting a fetid fluid which communicates its disagreeable odour to everything it touches. This seems the inherent property of all aphidivorous insects, and it may possibly be a wise provision for their safety, for neither bird, beast, nor insect would be likely to enjoy so disgusting a morsel.

There has been considerable discussion on the question whether ladybirds, confine themselves strictly to an aphis diet; but I can assert positively that they do not. A ladybird may often be found secreted in the hollow of a plum or pear when thoroughly ripe—indeed, these fruits rarely exhibit cavities until they are thoroughly ripe—and the fact of the insect being taken in the act, as it were, has often been regarded as positive evidence that it was the excavator; but truth is on the other side. The cavity was made by a wasp, or a slug, or a snail, and, being made, the ladybird crept into it, and while in has actually so far departed from its usual custom as to nibble at the luscious pulp. The fact makes itself manifest by watching a ladybird when engaged on a plum. Its mandibles may be seen in motion under a lens of moderate power, and the diminution of the pulp after a time becomes very evident. But even in this matter the ladybird is guiltless of doing us an injury, for it only takes the leavings of others—fallen or decaying fruit, which we leave on the ground as useless.

Let me conclude by entreating my readers to spare and to protect these aphis-eaters wherever they may be found, and not to condemn the aphides, their friends and their foes, to indiscriminate slaughter.—*Field.*

CATERPILLARS AND CAULIFLOWERS.

DURING an excursion last September, near the town of Meaux, I observed in a bed of cauliflowers several rows of elder branches, planted about three feet from each other, and still retaining their faded leaves. On making inquiry as to the use and purpose of these,

the owner replied, "Some years since, one of my neighbours had several rows of cauliflowers planted near a hedge of young elders, and further on—in the same field and on the same day—he had planted another lot. These last, which were as carefully attended to as the others, and from which the caterpillars were constantly picked, were very much injured by them, and the crop was scanty, and, from its wretched appearance, hardly fit to offer for sale. The most careful picking could not dislodge the caterpillars from the hearts of the plants. On the other hand, the few rows which had been planted near the elder hedge were perfectly uninjured—not a caterpillar had touched them. The explanation of this curious fact is that the butterflies preferred laying their eggs on the leaves of the elders, which were completely devoured by their caterpillars." Ever since that time, the people of this neighbourhood stick branches of young elders among their cauliflowers, and, later on, when the caterpillars on these have reached a certain stage of growth, some cool morning before sunrise they pluck up the elder branches, throw them in a heap, which they cover with straw or dry grass, and set them on fire. As the cauliflowers are not yet fully grown, fresh elder branches are placed amongst them."

As it is natural to conclude that other cruciferous plants might be protected from caterpillars in this way, a supply of elder branches will be a desideratum. This might be supplied by planting a piece of waste ground with elder, at a distance of a yard apart, heading them down close to the ground like osiers. The result would largely repay the trouble in the saving of time which is lost in caterpillar picking, a process which cannot, moreover, always be relied upon from the difficulty of performing the operation thoroughly and efficiently.—*Correspondent of "Revue Horticole."*

EFFECTS OF A ROOKERY ON VEGETATION.

If there were not some compensating influence at work, it is quite plain that trees would show far greater evidence of suffering from the friction of the feet of such a multitude of birds of no small size than is observable in most of our rookeries. But the excrement dropped by the birds, and washed into the earth by rain or drawn in by worms at night, does in fact greatly stimulate vegetation, and not least that of the lofty trees themselves.

Of the effect on the humbler growth, the following instance seems worth recording. I have a grove of tall horse-chestnuts, sycamores, and Spanish chestnuts, with here and there an oak. The upper soil is a light, dry, and weakly humus, of a blackish colour, and no great thickness; whilst beneath lies a yellow ferruginous rubble of sand and clay, intermixed with carboniferous freestone. Neither soil nor subsoil are such as can be described of even average fertility; and were it not that the trees had the benefit of two very favourable conditions, they could not have reached their present timber-like stature, though more than one hundred and fifty years old. They stand on a hillside, always a friendly site for timber, and the aspect is cool and northerly, another great aid where the soil is light and hungry.

Some twenty years ago, before the rooks had established themselves, so exceedingly poor and hungry was the ground, that no one native plant, save a little struggling and almost invisible dog's mercury, showed itself. Nothing but dead leaves lay on the surface, and repeated attempts to establish periwinkle, London pride, and common bramble (growing luxuriantly close by) altogether failed. I should add that no cattle or sheep had access to fertilise the surface.

At the present time, after twenty years of a moderately stocked rookery overhead (but no admission of more air by thinning of the timber), the ground is covered knee-deep by brambles, intermingled with periwinkle, grasses, stachys, nettles, &c., and the old trees are quite as thriving, if not more so. In another quarter an avenue of tall beeches is the scene of clamorous nidification. The soil and subsoil are here deep and good, but the site high, exposed to every wind, and very dry. Formerly the grass was poor and scanty under these beeches. Though the nests have never been numerous here, the airy avenue is a favourite trysting place of swarthy hosts from neighbouring localities on a fine morning, which come to sun themselves.

Under these trees there was last summer the finest growth of coltsfoot and fox-tail grass that I ever saw under beeches anywhere, and the tall summits overhead show no signs of harm or scathe from being the scene of so many loquacious parliaments.

By the way, on these tall beeches a curious approximation and fraternisation of rooks and guinea fowls used to take place; for it pleased the latter birds, at roosting time on mild evenings of April and May, to mount aloft very high, quite near to the rook nests; and there sat the two incongruous European and African groups, within a

yard or two of each other, vying with each other in discordant clamour, yet evidently recognising a certain mutual allegiance and respectful good neighbourhood. So they passed the nights for many weeks in spring, and it was very stormy weather indeed that would compel the guinea fowls to sit lower than their friends.—R. Carr Ellison, Dunstan Hill, Durham, in "Field."

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

Hairy Caterpillars.—These, almost without exception, are free from the attacks of birds, and, what may perhaps be an indirect consequence of their instinctive knowledge of this immunity, there are no caterpillars that so freely expose themselves to view. The cuckoo is almost the only bird that takes them. And even it does not feed upon all indiscriminately; for M. Grette de Pailleur states that he has never found, in all his examinations, any caterpillars of *Liparis chrysorrhoea* in the stomachs of any bird.

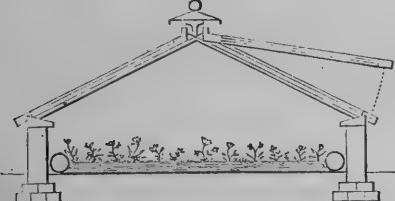

Lymexylon navale.—This is common in oak forests in the north of Europe, where it does much injury, by perforating the solid timber, and is occasionally so abundant in the dockyards there as to do much mischief. Linnaeus, who studied the life history of the insect, ascertained the period at which it made its appearance in the perfect state and when it laid its eggs, and recommended that the oak timber in the dockyards in Sweden should be sunk under water at that period. This was done with perfect success. The insect, therefore, has always had a certain interest of its own for the entomologist, which is not diminished by its being rarer in other districts than in those infested. It is rare in this country, and used to be rare in the neighbourhood of Paris; but it is curious, as showing how rapidly an insect scourge may be invited by producing abundance of pabulum, that this year it has ceased to be so, it having been taken in great quantities in the dead oak left lying in the forests, which had been cut down by the Prussians. The dead oak timber has apparently served as an attraction to bring it from distant quarters.

Worms on Lawns.—Will some of your readers kindly inform me what are the best means of destroying worms on lawns? I have a bowling-green, consisting of 3,000 square yards, which is infested with them; I have killed thousands with corrosive sublimate, but thousands more seem to come to the funeral of those that are dead. At the present time, while the ground is damp, the worms form innumerable little mounds of earth on the surface of the green, which, when the roller goes over them, are flattened on the grass, completely spoiling the green. Last season, being a wet one, I had great trouble from these worms, and used a large quantity of sublimate. Can anyone give me a better remedy?—J.B.

GARDEN STRUCTURES.

A WARM FRAME.

I THINK all interested in horticulture would be pleased to see two new frames which I have built, one hundred feet long by eight feet wide. By a simple piece of machinery the ridges are lifted, though so long, with the greatest ease, thus giving air without the trouble of opening the lights. A four-inch pipe goes round each frame, connected with a hothouse, and fitted with a valve. Each light is hung on pegs of iron dropping into a hook, so that they can be lifted off to paint. The lights open as if connected by hinges; their being movable is a great advantage. The bottom of the frame

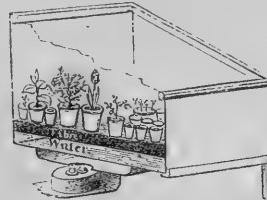

is filled with cocoa fibre refuse, in which the pots are plunged. Now for its, or rather their, advantage, for I was so pleased with the first, built in 1868, that I built another in 1869. They are ventilated in a few seconds, without cold wind playing on the plants. There are no hinges to get fast with rust or to break. They are safe from frost. The plants are near the glass. There is room for a man on his knees to work inside plunging plants when the lights are down. The pots being plunged in cocoa fibre refuse (which is clean, pleasant to handle, and free from insects and snails), there is little or no evaporation from the sides of the pots, and the plants seldom want watering. These frames are filled with seedling geraniums and tricolor

geraniums; and all who have seen them are pleased and surprised at their appearance. They look as if growing in an open bed in summer weather. Now, if these plants had been kept in greenhouses, they would have required watering every few days; but the frames have only been looked over once a week, and the plants have not been watered once a fortnight, except the row nearest the pipes. In watering, say, 5,000 plants, the difference between the labour required to do it once a fortnight and six times is something considerable. But this is not all; the plants are not chilled, the goodness of the soil is not washed out by such frequent waterings; and again, the cocoa fibre refuse being so perfect a non-conductor, the roots are kept in a more equable temperature than by any means with which I am acquainted. I shall be glad to show these frames to anyone.—J. R. Pearson, Notts, in "Field."

A GOOD AND SIMPLE HEATED PLANT CASE.

We have much pleasure in calling attention to a plant case invented by Mr. Peter Barr, which is most effective in raising seedlings and growing plants which require a genial warmth. Our illustration saves us the necessity of describing it. Below the "fibre" and the "water" the section shows a hollow chamber, and below that a little stand supports a lamp, the heat from which enters the chamber and escapes through small perforations in its sides. This lamp works

very well, simply requiring trimming night and morning, and replenishing with oil; the best colza oil is used. There are two patterns of this case—one rather deep, in which small stove plants, &c., may be grown; the other shallow, and more suitable for seedlings, cuttings, and other dwarf subjects, which are thus brought much nearer the glass. They are manufactured in several sizes. These cases will be found very useful by persons who wish to raise seedlings or grow tender plants in a dwelling-house, or in a cool greenhouse, orchard-house, or conservatory. This is a modification of an improvement on the Waltonian case.

THE PROPAGATOR.

RAISING SEEDS OF HARDY AND TENDER PLANTS.

Good seeds are of great importance towards the success and enjoyment of a garden, but to have a clear idea of the best and simplest way of raising them is very much more so. The seedsmen may have a good deal to answer for, but in the great majority of cases the blame is wrongly laid on their shoulders. The "bad seed" of the amateur very often means mismanaged seed.

The first thing the sower should do is to classify his seeds—at least, in all cases where there is a variety of tender and hardy plants to be sown. They should be classified according to the positions in which it is intended to raise them—in the hotbed, frame, open air, or as the case may be. Then each packet should have a wooden label written for it, and affixed to the packet by a kind of matting. This will save a good deal of trouble when a favourable time for sowing comes, as the sower will not have to cease his sowing every moment to write a label. Mistakes are also less likely to occur when the proper writing of the labels forms an operation by itself.

The following rules may prove useful to the inexperienced in the sowing of seeds in pots:—

1. All pots and pans used for seed sowing should be well drained in the ordinary way; and, as fine soil is much employed in seed sowing, a layer of dry moss or of roughish soil should separate the drainage from the fine soil above.

2. The soil on the top surface of all pans, pots, &c., used for seed sowing should be finely pulverised by sifting, not only to allow the seeds a medium in which to root readily and freely, but also one in which they may be divided with little injury to the roots.

3. Good sandy loam may be taken as the base of most soils used for seed sowing, but it should always have nearly half its bulk of finely pulverised leaf-mould, peat, or some vegetable soil in it, and

fully one-fourth of the whole should be of sand. Where vegetable soil is abundant, it may be employed almost exclusively, always however with the addition of fine sand.

4. The soil should be made perfectly firm and level in the pots, particularly in the case of small seeds. This is most important:

5. All small seeds should be sown very much thinner than is customary. Very often they are sown so thickly that the poor little plants can do nothing but illustrate the "struggle for life," and, when drawn up and stiolted in this way, the whole batch often perish from mould. Sow thin enough to permit of every plant having room to unfold its leaves when it peeps above the ground. In nine cases out of ten one thousand seeds are sown where one hundred would have sufficed.

6. It is a usual plan to cover all seeds with a covering of soil about equal to their own size; but in the case of large seeds, like those of the castor-oil plant, for example, little nicety as to covering need be observed, as they will push up through a much greater depth of soil than we can give them in pots or pans. It is with the small seeds that the care is required. In their case a perfectly level firm surface is, above all things, necessary, and very finely sifted sandy soil; for very small seeds it may be nearly all sand. In the case of the most minute class of seeds, of which the calceolaria is an example, it is better not to cover at all, but, having made the soil perfectly firm and level with the bottom of a smooth pot, or circular piece of wood with handle attached, water it with a fine rose; and, as soon as the water has disappeared, sow the seeds on the surface. Many very small seeds do not start from being too deeply covered, and, even some not very small ones often fail to vegetate from the same cause—the Chinese primula, for example.

7. All seeds sown in pits, frames, or houses require shading during sunshine; and it is particularly necessary in the case of the finer kinds of seeds sown on the surface. As these must first put forth their delicate little rootlets on the surface, an hour's strong sun would completely say the life out of them. For frames, tiffany, thin canvas, or mats will serve. For a few dozen pots of seeds sown in a hothouse, there is nothing better than a newspaper spread over the pots, and supported by their labels. Where a number of different kinds of seeds are sown together in a frame, many kinds will be an inch above the surface, and with perfectly developed leaves, before others have shown at all. It is desirable to frequently remove and harden off those that are well up; as by doing so we are enabled to leave the frame, or pit, or handlight, in the darkened condition that is desirable for the seeds not up.

8. Do not water seeds immediately after being sown, but when they begin to come freely they will be very thankful for a good watering of a fine morning when dry. As a rule, water them with tepid water from a fine rose. Of course, this applies to indoor seeds only.

Next let us take the various classes of flower seeds, hardy, half-hardy, perennial, biennial, stove, and greenhouse seeds.

Hardy annuals usually flourish in any ordinary garden soil, and merely require a slight covering, according to their size. Half an inch suffices for the largest kinds, such as the lupins—that is, half an inch over the seeds; whereas the smaller kinds, such as viciaeas, &c., require but a mere sprinkling. We usually have a barrowful of sifted potting refuse, or some other not over precious fine, free, and sandy earth at hand for covering them; though, if carefully and neatly covered with a little of the ordinary earth, they are quite safe. But the quickest, simplest, and best way is to have some sifted earth at hand, and then the depth of covering required by each may be regulated with ease. It is best to take this fine earth up in handfuls, and scatter it broadcast over the seeds, or to put some in a convenient sized flower-pot, and then scatter it with the hand. Of course, a nice mild day should be chosen for this and all similar operations, and the soil should be dry and friable, that the sowing may be made with comfort and facility. These and all seeds should be sown in lines or rings, not in broadcast patches, because when sown in line the difference between the plants and weeds can be seen in a moment, when both come up thick after a few weeks; whereas, if sown broadcast, all come up together, and unless an experienced hand familiar with the youngest aspects of the plants, you may not be able to distinguish them from the weeds. Garden ground is generally full of the seeds of weeds, and these usually come up freely among flower seeds sown in the open air. They should be removed from among the annuals as soon as observed. When once the annuals get a little start of the weeds, the rudest garden workman may distinguish them. Hardy annuals are like grass. They may be sown in the open ground at any time without fear of failure. It is, however, needless to sow them at any other time than in autumn or spring—chiefly in September and March—and early or late in spring or autumn, as the bloom may be required. Hardy annuals are in most instances, however, improved by being sown in

autumn. For example, there is as much difference between a bed of the bluebottle or corn-flower (*Centaurea Cyanus*) sown in autumn and one sown in spring, as if they were two different plants, the advantage being all in favour of the autumn sown subjects. The same is true of the sweet pea and many other plants.

Biennials, among which are some of the prettiest plants used for spring gardening, generally are best sown in June and July, but particular requirements or soils may make it desirable to modify this. They should be sown in some spare spots in the kitchen garden, and in autumn transplanted to the places in which they are to bloom the following spring or summer. It is a class worthy of much more attention than it usually receives, and includes not a few fine old garden flowers, like the Sweet William. This, however, and a good many others of the class, may be sown in nursery beds in spring.

Half-hardy annuals form an important class, and with them may be sown such bedding plants as are usually raised from seed. A gentle hotbed is the best place for the generality of these, and if the bed be covered with fine soil, and the seeds sown directly upon it, so much the better. The greater number of half-hardy annuals will succeed perfectly if sown in pots in a cold frame or pit, with the lights kept close and shaded till the seeds germinate. No matter how they are raised, they should be gradually exposed to the open air, so as to be quite inured to it before the end of May, or, in the case of the quickest growing and hardest things, long before that time. In the case of those sown directly on the soil of a gentle hotbed, the lights may be removed. Some of this class may be sown in the open air when the earth becomes sufficiently warm—say about the beginning of May—but many people lose them by sowing earlier.

Tender annuals are a small class which require to be sown in a warm frame; a melon or cucumber frame, or nice warm stove, will do admirably. Give them and all other indoor seeds plenty of light when once up; in other words, keep them near the glass to prevent their being drawn.

Hardy perennials.—Some of the finer and rarer sorts, slow-growing alpine plants, &c., should be sown in pots or pans, and carefully looked after till strong. The month of March is, generally speaking, the best time for sowing these. The gentians, many North American plants, some anemones, paeonies, cyclamens, and various other perennials are slow to germinate, and should be waited for, keeping the pots clear of weeds and in a cold frame during summer. The hardiest kinds may be raised abundantly on a bed of fine earth in the open air—say, on a favourably situated border. Sow in April, or, indeed, at any time that the seeds come to hand or become ripe. By having a little nursery of young plants of this kind, vacancies may be filled up on new plantings made at any time. Many of the finer spring flowers come into this class, as well as the showy summer border flowers. Hardy perennials may be sown in autumn, with great advantage, or, indeed, at any time during the summer, when the seed is ripe. Cover, as usual, in proportion to size, and sow in little drills—say half an inch deep—made by laying the straight handle of a rake or hoe across the bed, and then gently and evenly pressing it down. Do not sow perennials in the place in which they are destined to flower, but plant them from the seed beds into such positions.

The taste for sub-tropical plants, palms, &c., that is now arising is likely to cause many to take an interest in the raising of plants requiring a warm temperature. Their name is legion, and they differ much in size, from palm seeds as big as eggs to minute ones requiring scarcely any covering. All stove seeds should be sown in spring, at any time from January to the end of April, but if obtained in early summer it will be better to sow them at once than lose another season. They should rarely be sown in autumn, except where there are very good appliances, as otherwise they are apt to die off in winter. One of the most important points in the raising of seeds of stove plants is keeping them near the glass from the moment they have appeared above the earth, and they should be potted off when very young. A few day's neglect of these points may spoil them. There is not, nor is there ever likely to be, a better position for raising seedlings of stove plants than the old-fashioned hotbed or pit heated by stable manure or leaves. The stove with a tan bed is also excellent, and they may also be raised in the ordinary plant stove. In it, however, we have always found ants great enemies to seeds, eating every grain of some kinds in a single night.

Greenhouse seeds are at present required by a larger class than the preceding, and are, as a rule, much better started in the places recommended for the stove seeds than in the greenhouse; and, failing a stove, a good hotbed suits them to perfection. If they must be sown in the greenhouse proper, it would be wise to plunge the pots in moss or cocoa fibre, so as to counteract the effect of the dry air common to greenhouses. There are palms for the greenhouse

as well as the stove. We have just seen a list of twenty-eight kinds of palm seeds in a seedsman's catalogue, but everyone of these we should place in a brisk hotbed, and give them a vigorous start. A gentle hotbed will prove an agreeable starting-place for seedlings of pelargoniums and plants of that type. Cinerarias should be sown towards the end of summer in a cool frame or pit, and with them the handsome herbaceous calceolarias.

With stove and greenhouse, as well as many other seeds, it is often necessary to have a good deal of patience. Nothing is commoner than for people to throw away pots of seeds, under the impression that they are dead because they have not come up as soon, or nearly as soon, as soft and vigorous kinds, while all the time the seeds are as sound as can be. Some subjects take a long time to germinate; and some, that naturally start immediately after they fall from their pods in autumn, seem to become hardened by being kept over the winter in drawers, as our convenience requires. Therefore, we should always satisfy ourselves that seeds are dead before throwing them away.

R.

THE ART OF GRAFTING.

(Continued from p. 234.)

PLANTING.—A young, compact, well-rooted plant should be selected. If more than one year old, it should have been transplanted. Before planting it is dressed, that is, its roots and branches are pruned and cleaned. The stem should be cut down to about ten inches from the collar, if the graft is to be low down, and about four inches in cases of cleft and crown grafting. The side branches should be cut away, or rather shortened. Evergreens and certain kinds with hollow wood, as the sweet and horse chestnuts, the walnut, and the tulip tree, should not be topped. The trees should be planted in rows, so that those of each successive row may be opposite the spaces of the preceding one, and at distances calculated according to the future size of the subjects. A space of twenty inches between the plants, and thirty inches between the rows, is the average in well-kept nurseries. This may be increased or diminished as the plant is likely to branch much or not, and in proportion to the length of time it is to remain in the nursery. The planting is done with a dibble or spade. If it is carried on slowly, or in a time of great heat, the roots of all the plants should be dipped in mud, or in a mixture of soft clay and cow-dung, which will prevent them from suffering by being kept out of the ground. The soil should be well pressed down after planting. Watering will generally be necessary the first year only, and then chiefly at the commencement of vegetation.

CUTTING DOWN THE STEM.—During the first year we confine ourselves to the culture and care of the plant. We will suppose that it is intended for a standard for a tall stock: we shall speak further on of low stocks. After the first year of growth, or before the second commences, the plant intended for a standard is cut down to within two inches from the surface of the soil. This operation should not be performed until the month of February or March, when the sap is at rest and the winter frosts are no longer to be feared. During the summer we select the finest shoot which has sprung from the stump, and bend and tie it up to the stump so as to give it a vertical position. All the other shoots are cut away; and in autumn the stump itself is cut away. Should it be found difficult to fasten the shoot properly to the stump, a stake may be used instead. The following year the young tree will be allowed to grow on. If it should turn out badly, it must be cut down a second time, or else grafted at the base with a vigorous kind, which, when it has grown sufficiently, will furnish a suitable stock. This cutting down is, of course, unnecessary in the case of fine, stout, vigorous, and straight stocks; but with doubtful subjects it is better to practice it.

TRIMMING THE YOUNG STOCK.—This consists in cutting off the useless branches. In general, the strong ones are removed altogether, being cut close to the stem; the medium-sized are shortened, and the weak ones left as they are. The shortened branches may be left from two to ten inches long, always retaining some of the eyes. It should not be forgotten that cutting the branches weakens a tree, and that retaining them has the opposite effect. In this operation therefore, the healthy growth, as well as the form of the stock, should be

considered. When the stem is strong, it will not suffer from the removal of the lateral branches from the neck up to the place intended for the graft. In short, strong stems should be cut closely, weakly ones only partially, and poor ones as little as possible. In cutting away a branch entirely, it is well to leave a small portion with a bud on it at the base. In making the cut, the direction of the pruning-knife should be from below upwards, as it requires very great skill to make a clean cut in the other direction, and avoid tearing the wood. To prevent the growth of useless thick branches near the terminal shoot, the buds on that part should be pinched off in the spring. The young leading shoot should be trimmed moderately; its branches being shortened where they are too long, and the others left as they are. It should not be topped until it has grown at least a foot beyond the height intended for the graft.

PREPARATION OF THE STOCK FOR GRAFTING.—Whether the stock shall be headed down or not will depend on the mode of grafting employed. The removal of the head, indispensable in crown-grafting, is effected at the moment of commencing the operation, as the wound is then not likely to become inflamed, being covered immediately with the grafting-wax as soon as the graft is in position. However, when large trees are grafted, they should be cut some weeks beforehand; and the same may be said of all kinds of grafting which are done at the time when the sap begins to flow, and which require the stock to be cut in this way. During the dead season, after the heavy frosts have passed, the head of the stock should be cut down to within about four inches above the place where it is intended to insert the graft. At the time of grafting it is cut finally, or else the wound is simply trimmed by slightly reducing the length of the stock, so that the graft may be placed in contact with a living and healthy part. Side-grafting does not require the removal of the head of the stock. It is sufficient that the part which is to receive the graft should be clear, and that the shoots for four inches above and below it be cut away. The upper branches will then continue to draw up the sap, and the lower ones will promote the growth of the stock. In summer graftings, the stocks should be trimmed a month beforehand. The flow of the sap, which is diminished by this operation, will then have had time to recover its activity, and will contribute to the success of the graft. But cutting off superfluous branches a week or so before grafting, would be followed by a check in the flow of the sap at that time, which would be very detrimental to the uniting of the parts of the graft. It would be better not to cut them till the moment of grafting, as the junction would be complete before the vegetation had suffered much abatement. These operations should be performed with keen-edged tools, and by a skilful workman, who would neither bruise the stock nor leave stumps full of supplemental buds. Resinous trees do not require this preparatory treatment. With the exception of bushy kinds, stocks grafted low down the first year of their planting have seldom any branches to be removed. It is sufficient to wipe with the hand or a rag the place which is to receive the graft. Usually grafting is performed on the low stem, which has been shortened down to ten inches at the time of planting. In grafting briars, any prickles that are in the way should be removed, as well as any buds of the stock that might come under the bandage. This is done at the time of grafting. If, from any cause, the flow of the sap is arrested in mid-summer, vegetation should be excited by liquid-manure waterings, moving the soil about the roots, and a mulching of old hot-bed manure.

SELECTION OF THE SCION.—The tree, branch, or shoot which is grafted on the stock, and which it is desired to propagate, is termed the scion or a graft. The plant from which it is taken is called the parent plant or tree. The scion should be of good quality, healthy, hardy, and of sound constitution. An unsound scion propagates whatever defect it possesses, and a bad selection repeated for several generations leads to a degeneration of the variety, which is, however, local and not general. The proof of this is furnished by the sub-varieties of trees with variegated leaves. The variegation is propagated by grafting, yet the type remains none the less exempt from the disease which produces it. Though the defect is not always visible as in the case of variegation, propagation with inferior scions is

sure to lead to degeneration; one should be very cautious about taking scions from a tree of unknown quality. In nurseries great importance is very properly attached to the vigorous condition and true name of the parent trees. These, while supplying scions, are also carefully trained. They are pruned in order to obtain a greater number of branches, but care is taken to reserve, from one year to another, some branches uncut, if it is desired to have scions that will arrive at maturity more speedily. The shoots which are developed on the upper part of an uncut branch ripen their wood sooner than any others. When a growing tree is to be grafted into another, it should be planted for at least a year beforehand, near the subject on which it is proposed to graft it. The scion should be cut from the parent tree just before it is used. For grafting during the dead season, the scions may be cut some time beforehand, but not until the sap has gone to rest. They may be kept in good condition until they are wanted by burying the ends about four inches in the ground, in the shade of a house or evergreen tree. Long branches should be buried deeper and laid in a slanting position in the trench. They will keep much longer if placed in an ice cellar, buried horizontally in fine sandy gravel such as is used for walks. Graft buds should be taken from the branch which produces them just before they are used. A scion should never be allowed to suffer by long exposure to the air or dampness. The cactus family furnishes individuals from which scions may be detached and exposed to the sun for several months without the least injury; but we are now occupied with woody plants, and not with hothouse or herbaceous kinds. Scions with the leaves removed may easily be sent considerable distances during the repose of the sap, provided they are kept cool. They should be wrapped in moss, and the end of each stuck into a potato, artichoke, &c. When they arrive at the end of their journey, they should be put into water for a few hours, and then laid in a shady place. If the bark is wrinkled, they should be entirely covered with soil in a trench and left thus buried for two or three weeks. The same precautions should be taken with shoots sent, during the time of vegetation, either by post or other mode of speedy transport.

C. BALLET'S "l'Art de Greffer."

(To be continued.)

Beauty of Mountains.—The best image which the world can give of Paradise is in the slope of the meadows, orchards, and corn-fields on the sides of a great Aip, with its purple rocks and eternal snows above; this excellence not being in any wise a matter referable to feeling, or individual preferences, but demonstrable by calm enumeration of the number of lovely colours on the rocks, the varied grouping of the trees, and quantity of noble incidents in stream, crag, or cloud, presented to the eye at any given moment.—*Ruskin.*

The Elephant's Foot Plant.

THE INDOOR GARDEN.

THE ELEPHANT'S FOOT PLANT.

(*TESTUDINARIA ELEPHANTIPES.*)

THIS curious plant is a native of the Cape of Good Hope, where it is locally known by the name of "Elephant's Foot," owing to the fancied resemblance of its singular root-stock to the foot of that animal. It is known also in this country as the tortoise plant, the shell-plated covering of that animal

having suggested its generic name, *Testudinaria*. Root stocks of a large size are sometimes brought to this country, ranging from one to three or four feet in diameter, the exterior portion being cracked into angular protuberances, as shown in the figure. After they arrive a good plan is to place them on charcoal, broken small, and keep them free from water until the stems begin to grow, after which they may be freely watered while the growth of stem continues. It sometimes happens that they begin to grow at once after being placed in the greenhouse, but they oftener remain from one to three years before they push forth stems. The stem is of annual growth, and, after flowering, it dies down like the stems of ordinary herbaceous plants. When this takes place, the root-stock should be kept dry until it again begins to produce a fresh growth the following season. An ordinary warm greenhouse or conservatory is the proper place for growing it, and also for keeping the plants during their resting period. When put in a dry stove the growth is generally weak, and the root-stock soon gets covered over with plant scale insects. If trained as represented in our woodcut, large plants produce a very pretty effect during the summer months. The flowers are inconspicuous, of a greenish colour, and hang in short racemes. Very light, sandy soil should be used to grow the plant in. M.

Eucharis grandiflora.—This is one of the most useful of stove plants, and particularly easy of cultivation. Under the following management, it may be had in flower six or eight times in one year:

Pot the plants in any rich light sandy loam, and drain well, placing them in bottom heat, if possible, close to the glass, and expose them to the sun well when out of flower, in a temperature of from 65° to 85°, syringing them three or four times a day in bright weather, and giving a good supply of water at all times, and liquid manure occasionally. Mr. James Tapling, of New Jersey, has flowered some plants nine times this last year in ten months. The flowers may be kept in a cool state for a fortnight in water in a cold place. They are rather large for hand bouquets, but particularly useful for table decoration, head flowers, wreaths, churches, &c. *Eucharis candida* is very similar, but smaller.—W. HOWARD, *Balsam*.

Lily of the Valley.—I have grown this as recommended at page 168, and my plants never show any symptoms of blooming in the autumn. I have some coming into blossom now which have been treated exactly as stated in the article to which reference has been made.—C. P.

VANILLA CULTURE.

BY E. BENNETT, ENVILLE HALL, STOURBRIDGE.

As a stove climber the vanilla may safely be asserted to be one of the most interesting; its green, fleshy leaves, singular Cattleyan-like flowers, delightfully fragrant fruit, and great length of roots, make it particularly well worth attention. When properly treated it is a plant of very rapid growth. A cutting placed in one of the pine pits here in August 1870, has made upwards of 240 feet of growth, and I look forward to its producing fruit this season. It grows freely in a mixture of peat, charcoal, and mortar rubbish. It may be trained in any form, and will attach itself to rough walls, wood, or iron. Having naturally little tendency to branch, I frequently stop my plants in order to make them throw out sideshoots, and in that way secure a greater amount of fruit-bearing wood. When at Osberton I tried several experiments with the vanilla, in order to find out the different temperatures in which the plants would fruit, and I came to the conclusion that for this purpose it is not requisite to keep up a high temperature. The largest plant at Osberton was planted out at the back of a succession pine stove, the temperature of which ranged from 50° to 65°, and sometimes much lower; this plant fruited freely every year. Indeed, one season I gathered off it upwards of 300 ripe pods, for which I obtained five first-class prizes. A second plant was planted in a fruiting pine stove, the temperature of which ranged from 60° to 85°; this also grew vigorously, and fruited well. A third was planted out in a house used for miscellaneous plants, the temperature of which ranged from 45° to 55°. This did not grow freely, but nevertheless bore fruit. I have therefore come to the conclusion that a temperature ranging from 50° to 70° is most suitable for the vanilla.

Major Trevor Clark has stated that the vanilla is a difficult plant to fruit; but failure doubtless occurs in many cases through want of knowledge of the art of fertilising the stigma, an operation requiring both care and skill. In the flowers of vanilla three sepals, and as many petals, surround the column which bears the anther and stigma. The first of these is

attached to the summit of the column by a narrow curved neck, and contains, within a cavity on its lower surface, the pollen masses. The curved neck just alluded to bends towards the lower surface of the column, where it rests upon an organ called the retinaculum, which interposes between the anther and the stigmatic surface of the column; this latter, projecting from the column, lies immediately under the retinaculum, and terminates a bearded glandular process, which covers the lower surface of the column. The retinaculum, which is concave towards the stigma, effectually prevents all contact between that and the anther; it is therefore necessary to remove the retinaculum in order that the anther and stigma may be brought together, and this is best effected by means of a pair of narrow-pointed forceps. These should be carefully introduced sideways between the anther and stigma, seizing the retinaculum and tearing it off in the direction of the anther. The pollen masses are then drawn out, pressed down on the stigmatic surface of the column, and the operation is completed. If this is properly performed, the setting is certain; if not, the flowers will drop. Where, however, fertilisation has been effected, the flowers remain for a considerable time, or continue fixed to the fruit, which in twenty-four hours will be perceptibly elongated and in about twelve months will be ripe. It is requisite, therefore, that the vanilla should be planted and trained, so that when the flowers expand they may be easily got at. They generally open during the night or early in the morning; therefore the best time to fertilise them is in the morning, and this must be daily attended to as long as the plant is in bloom. The opera-

Well-Grown Vanilla in Large Plant Stove.

tion is so familiar to me now that I could venture to rely upon nearly every pod coming to maturity, although I must confess that I found artificial fertilisation difficult to accomplish at first.

I am of opinion that it would be a good speculation to grow vanilla in this country for commercial purposes, the price charged for imported produce being very high. English-grown pods are very highly flavoured, much more so than those which we receive from Mexico; a large pine stove, where the plants could be removed during the few weeks when the vanilla flowers are setting, would be all that would be needed.

I may mention that I generally keep the temperature rather high during the time the plant is in flower, and I use the syringe freely on it during the summer months. Insects never trouble me, and a little shade during hot weather is all that is required.

Considering the length of time the vanilla has been in this country (over seventy years), it is surprising that more fruiting plants of it are not to be met with. Indeed, I have seen many plants of it that do not produce even a flower, a circumstance which I attribute to not getting the wood well matured, for, if not well ripened and hardened, it will not bear flowers. To aid my plants in maturing their wood, I at times allow them to get almost dry and parched.

The accompanying illustration is a good representation of the vanilla in a large stove when in good health and growing freely.

THE SHRUBBY CALCEOARIA.

I AM an old gardener, too old for garden work, but I still take a deep interest in all that is connected with that happy employment, in which I have passed my life. Although I can dig no more, I rejoice to read in THE GARDEN the sayings and doings of those who are young and strong; and though I can never again march to battle, I can still shoulder my crutch and show how fields were won when I contended for victory at our horticultural exhibitions. And, with your leave, I should like to say a few words about a plant which I grew with great success, and for which I took many a first prize—the Shrubby Calceolaria. Perhaps I may first be allowed to say where I commenced the cultivation of this beautiful flower. It was at Caunton Manor, where I lived for more than forty years as gardener to Mr. Hole, the father of the gentleman well known to your readers as a writer about roses. I hope his reverence will forgive me if I say that, having known him from a child, I can well remember how he first showed his great liking for horticultural pursuits. It was in gooseberries. I grew them for exhibition, and the trouble I had in preventing him from judging them (by flavour) before the show, I am not likely to forget.

And now about the calceolaria. The best kinds I ever saw—and I have seen those shown in London, and those sent out by Mr. Thomson, of Dalkeith, and Mr. Henderson—were raised by Mr. Major, of Knotsthorpe, near Leeds. There was more quality about them, both in shape and colour, than I have seen in any others.

They may be struck from cuttings at almost any time except in the winter months. If struck in spring, they will flower in the autumn; if struck in the autumn, they will flower in the following spring. These cuttings, about three inches in length, should be inserted about one inch in small pots filled with a light, sandy compost, and placed under a bell glass in a gentle heat. In a month or five weeks this glass should be gradually raised for a few days before potting the rooted cuttings, when they should be again placed in heat until they are established, when they should be removed to a frame or greenhouse. They must be repotted two or three times, as they require it, with plenty of drainage; their last shift being into pots seven inches in diameter. The soil should be a mixture of turf-loam, which has been taken from old pasture land and lain for a year, leaf-mould, peat, cow-dung, silver sand, with a small quantity of charcoal intermixed. They must be well watered when in a growing state, syringed in the evening once or twice a week before they come into bloom, with manure water occasionally given to the roots. They must have all the air you can give when the weather is favourable, and when they begin to flower they must be shaded from the scorching sun. They must be tied out as they require it, and, if carefully cultivated, may be grown to be three feet in diameter. EVAN HIRST.

PERPETUAL CARNATIONS.

This is the time to look up the old plants and get them in a little heat, so as to procure some small grass for cuttings, which should be put in as soon as possible. They will strike as easy as fuchsias in bottom heat during February, March, April, and May. Pot off as soon as rooted, and replace in a warm dung bed or pit until well established. Gradually harden off in cool frames until May; then plant out in some open place or keep potting on as the pots get filled with roots, stopping the plants as they may require it.

The plants must be lifted from the open ground in September and put in pots, staked, watered well, and placed in a shady place for a few days; then exposed to the sun again; place them under glass before they get saturated with the autumnal rains. When the pots get full of roots, give weak liquid manure once a week. In case the green fly appears, apply tobacco powder or a solution of quassia. Do not let any weeds get among them, or mildew will make its appearance; if it does, then apply flowers of sulphur. In the spring plant the old plants against a wall or in a row across the kitchen garden, and strain a few wires across to tie them to, and they will continue to flower the whole of the summer. Strike a fresh lot of plants every year, as old plants are unprofitable in every form. Some leaf-mould, dung, and sand in equal parts, make a good compost for them. With very little trouble, they may be had in flower all the year round in any ordinary greenhouse, with a little heat during the winter months. The following are the best kinds:—

CONSERVATORIES IN THE NATURAL STYLE.

I HAVE read with interest M. André's remarks on this subject, and I think that, on the whole, he has shown considerable skill in grouping and working out the details of his plan.

Taking the temperature given as the right amount of heat in winter, I think the house in the daytime would be too hot to be enjoyable. Ladies, if at all delicate, do not care about entering a very warm house, highly charged with moisture, on a cold winter's day. I must confess, however, to a weakness for bottom heat, judiciously applied, when easily accessible and under control. And, as far as any experiments I have been able to carry out, I have found that plants from warm countries, if treated to a moderate amount of bottom heat, will thrive in a lower atmospheric temperature than is generally considered safe; in fact, I should think in a house of that kind it would not be desirable to encourage rapid growth, but, on the contrary, a temperature just sufficient to keep the plants in vigorous health would be more suitable. If rapid growth were encouraged, many valuable plants, such as palms, &c., would soon get too large for the house, and would have to be removed. Many orchids and winter flowering stove plants might be introduced in groups. Ferns and orchids might also be suspended from the roof, and changed when necessary. Altogether, such a house might be made very enjoyable, and the work in connection with it reduced to a minimum. However, it is only in very large establishments where the tropical conservatory will find a place at present; but I certainly should like to see M. André's idea, on some modified form of it, carried out in many of the large, dark, dismal conservatories to be met with in many country establishments. All architects, I think, ought to possess a little knowledge of plant growing, just sufficient to convince them that plants are endowed with life, and that, in the winter, light is absolutely necessary to their well-doing. Nothing is more calculated to try the patience of a man than to place him in charge of one of our highly-finished architectural conservatories, and tell him it must be kept gay through the winter. I have seen hundreds of plants carried almost weekly into a house of this kind, and nearly ruined when brought out again. Therefore, I should like to see M. André's plan tried first in this direction; and we have abundant materials at command, as suggested by Mr. Baines, from China, Japan, and the higher ranges of the Andes. Several of the Australian tree ferns and palms, acacias, &c., would also do well, keeping the lightest spots for the groups of flowering plants. Many things from the Cape of Good Hope and the higher latitudes of the East Indies would also be available; in fact, there is no lack of materials, and I believe it would not only be more satisfactory to the owners of such houses, but would relieve the hard-worked gardener from some of his responsibilities. In conclusion, I must protest against the use of white stone for paths in conservatories, especially if they are kept white by pipeclay. I know something about the labour required to keep a collection of plants clean when the dust from such a source settles on them. Minton tiles, or cast-iron of a neat pattern, would be much better.

E. HORNAY, Ramsey Abbey.

[Conservatories on M. André's plan have been repeatedly formed with the most perfect success by him and others; he did not write suggestions only, but simply described what he had done, and what is perfectly practicable with the materials he indicated].

THE CHINESE PRIMROSE.

[THIS, though not difficult to grow, is one of those not numerous plants that are seen in much fresher and better condition in Covent Garden Market than in private gardens. We have, therefore, much pleasure in publishing the following article on its culture, by Messrs. Hayes, of Edmonton, who are the best of all cultivators of this charming plant. Messrs. Hayes have been cultivating Chinese primroses for the last twenty-five years, and have had considerable influence in popularising them. They supply Covent Garden and other London markets with some ten thousand of these beautiful primroses annually.]

We generally make two or three sowings of these, the first early in March, the second at the end of April, and the third at the end of May. Any time in May will be early enough if they are not wanted in bloom until Christmas, but if required in October and early in November, they must be sown in March, in order to secure good strong plants. To get the seed up successfully we adopt the following plan:—We sow in boxes instead of in pans, as is usually done, as we find from experience that the seed hardly ever comes up round the edges of the pans. The reason is simply this, the pan absorbs the moisture from the soil, and consequently the seed gets dry, and if once it gets thoroughly dry after it has been soaked through, it will never vegetate afterwards; a result which we have noticed over and over again. Gardeners, who have in general only a small quantity of seed, are very apt to sow it in a small pan; the result of which is, in many cases, failure in getting up the seed. If sown in a box you do not run so much risk, as the box does not absorb moisture so readily as pans. We sow on very old rotten dung, at least three or four years old, and we sow on the top of the mould, for the dung has now got into that condition, moistening it before the seed is sown. And when sown, we sprinkle a little silver sand over it—barely enough to cover it. We place a piece of brown paper over the box and keep it moist, never letting the paper get dry if possible, until the seed vegetates, when we remove the paper. Any shady place where there is gentle heat will suit them very well. Our reason for so fully entering into the matter of sowing is, we have repeated complaints of Primula seed not growing, while, at the same time, it grows with us well enough.

As soon as the young plants can be handled, we prick them off, putting four into a sixty-sized pot and keeping them close for a week or two, until they get hold of the pots, sprinkling them two or three times a day. As soon as the plants have become strong enough, we divide them and pot them off into small sixty-sized pots, and still keep them close in a frame, sprinkling as before two or three times a day, and when we find them getting established, we give them more air. When it is found that they require it we give them a shift into forty-eight or thirty-two sized pots, according to the size which it may be desired ultimately to have the plants. If they should indicate symptoms of blooming in August or September, we generally pick the flowers off, an operation which gives the plants strength.

The soil which we prefer for Primulas is well rotted leaf-mould or dung, and mellow loam, mixed in equal parts, with a little silver sand. We keep them in a shady situation during sunny weather, but we do not shade them if that can be avoided, that is we do not cover them over with mats, as that tends to "draw," and make them weakly instead of short, stocky, strong plants.

The best situation to keep them in during the summer months would be a north house, or a frame under a north wall; or the north side of a plantation, but not under trees. We would recommend leaving the lights open at night when the weather can be trusted, but by no means if there is any chance of a storm, as that would prove disastrous to them. For winter flowering you cannot give them too light a situation, the lighter the house the better, with as little fire heat as possible, just sufficient to keep off damp. A little liquid manure, very weak, will be found beneficial when the plants are pot-bound.

J. AND J. HAYES, Lower Edmonton.

FLOWERS FOR GRAVES.

In dealing with the planting of cemeteries in a former number (p. 146), no allusion is made to the planting of flowers round the graves: a custom of which let none think lightly, for it has its origin in the holiest of feelings—respect for the temple from which the indwelling spirit has gone forth. Graves are generally surrounded by a kind of external border for flowers, with a narrow stone coping, the centre being either left as a grassy mound or covered over with a stone. If any iron-work surrounds the grave, no prettier climber can be used than the Aimée Vibert rose; its snowy-white flowers and perennial dark green leaves render it the best kind for grave adornment. The Maurandias, both lilac and white, are delicate climbers. Ivy, of course, is always at hand. Spring is especially rich in flowers for the grave. Snowdrops may be planted in the grassy mound; but prettier still, are the lovely blue flowers of *Scilla sibirica*, either as an edging or dotted promiscuously on the turf.

In the border, Crocuses of every colour may be planted; the single red and white Tulips are very effective, and Hyacinths, red, white, and blue, or other shades. Then there is the Narcissus, the Poet's and double, and the pretty silver-paper-looking flowers of St. Bruno's Lily (*Anthericum liliastrum*)—all of which are desiderata, as are also the double Daisy, white and red; Primroses, single and double; Heartsease, and the Lily of the Valley. The new varieties of Forget-me-Not flower freely; and we may also have the snowy blossoms of the Saxifrage (*S. granulata*). Nor should Anemones, both garden and the blue wild (*A. apennina*), be omitted; the latter is a most desirable flower. Periwinkles, blue and white, carpet the ground. Where there is room for small shrubs, the golden Arborvitae should be introduced. As summer advances, the choice of flowers is more varied. In Edensor churchyard, near Chatsworth, under a simple gravestone surmounted by a floriated cross, repose the remains of the late Duke of Devonshire, the great patron of gardening. Sir Joseph Paxton lies in the same churchyard. Though ill-kept and unprotected, the Duke's grave looks very pretty, planted with the brilliant white flowers of *Viola cornuta*. This plant flowers so freely, that each kind, white or blue, is a great addition to grave flowers. *Gentiana acaulis* flowers well if not disturbed. The Mule Pink is an abundant flowerer; and the stately White Lily may be raised in pots and sunk in the border.

The tin troughs now made as crosses, circles, and in other forms, and filled with water, greatly extend the decoration of graves by means of cut flowers. The Germans make wreaths of ivy, in painted tin, which they hang upon their tombs. In the cemeteries at Paris, large sculptured marble vases are placed upon the grave slabs, filled with the choicest exotics. F. P.

HOME LANDSCAPES.—HARDY FLOWERS.

BY NOEL HUMPHREYS.

As a substitute for the fashionable geometric masses of geraniums or calceolarias how agreeable and picturesque would be the effect of a slightly-inclining border such as that represented in the accompanying illustration, from which spring forth fair flowers of many kinds, just as in some highly-favoured natural valley, which the disturbing hand of man had never cramped into formal patches. Improved taste in all branches of art is rapidly carrying us in the direction of principles which admit of nature being altered, and even improved, by art, but not subverted. Even the most advanced in horticultural art do not at present fully apprehend the best means of effecting the inevitable reform that is impending.

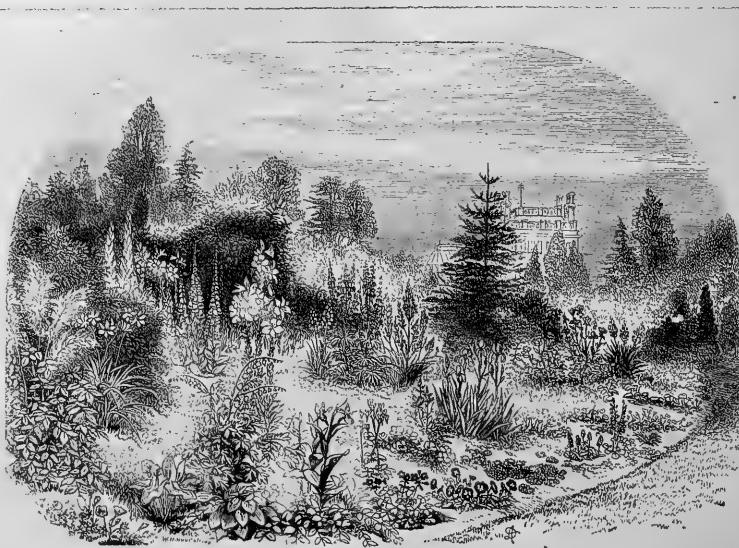

I well recollect, during a dinner-table discussion at the hospitable house of the late Mr. Loudon, suggesting a system of flower culture after Nature's own method—even making the plants grow among the turf, and leaving the surrounding expanse of green to soften and harmonise the colours. Loudon, with all his advanced taste, and with a fine mind, which, upon almost every other subject was entirely free from the slightest tinge of prejudice, could not, as a "gardener" carefully educated in the principles of the time, free himself entirely from the shackles of his art, and from existing custom, and he replied, "Such an attempt, even if the under treatment of soils and other conditions could render it successful, would only be a

poor and flimsy imitation of some small district peculiarly rich, in a botanical sense, and would not be *gardening at all*." There are still equally sturdy opponents to flower landscapes, whose opposition to all innovations, as they call them, are far more obstinate than that of Loudon, without a tithe of his well-earned right to express an adverse opinion upon the subject.

In the rage for uniformity, not only are flowers planted in set ovals, circles, squares, or other figures, with no touch of or speck of different colour from some other plant to break the monotonous mass of red, blue, or yellow; but the very grass of our lawns is to be equally monotonous, unbroken even by the sweet sparkling blossom of a single daisy, which would be, in fact, deemed an unpardonable blemish. And yet, what is the smoothest lawn—the most speckless, the most monotonously green—in comparison with the old manor-house lawns I recollect as a boy, softly freckled, ere the snows were well off the ground, with masses and isolated flowers of the pearly snow-drop, and a little later, with a gay sheet of daisy bloom; while late-flowering crocus, in twos or threes, struggled up among the

masses of *Dielytra spectabilis*, with its gracefully bending racemes of flowers, is nearly as hardy as the lily or the fox-glove; and close at hand the elegant Dog's-tooth violet, the red oxalis, and deep-purple pansy, are plants that positively enjoy our cold, uncertain climate; while masses of *Hemerocallis*, *Yuccas*; and *Iris*, all so carefully outlined by the artist as to be recognizable at a glance, are obstinately hardy even in our northern counties. Note, too, how beautiful is the perfectly hardy *Cypripedium*, and how distinct and pleasing are the hardy little succulent plants till recently so uncommon!

The only difficulty in producing a lovely floral landscape such as the one represented, would be the careful selection of such a series of plants as would, one after another, produce a succession of bloom during the whole of the spring, summer, and autumn: but this difficulty, with a little management and consideration, might easily be got over. An impediment, however, which might require more skill to surmount, would perhaps, be the one touched upon by Loudon, as narrated already, when he alluded to the *under treatment* as regards

A Mixed Border of Hardy Flowers.

blades of green, and expanded their delicate lilac petals to the autumn sun? Portions of our lawns, in suitable situations, may safely and advantageously be allowed to run wild.

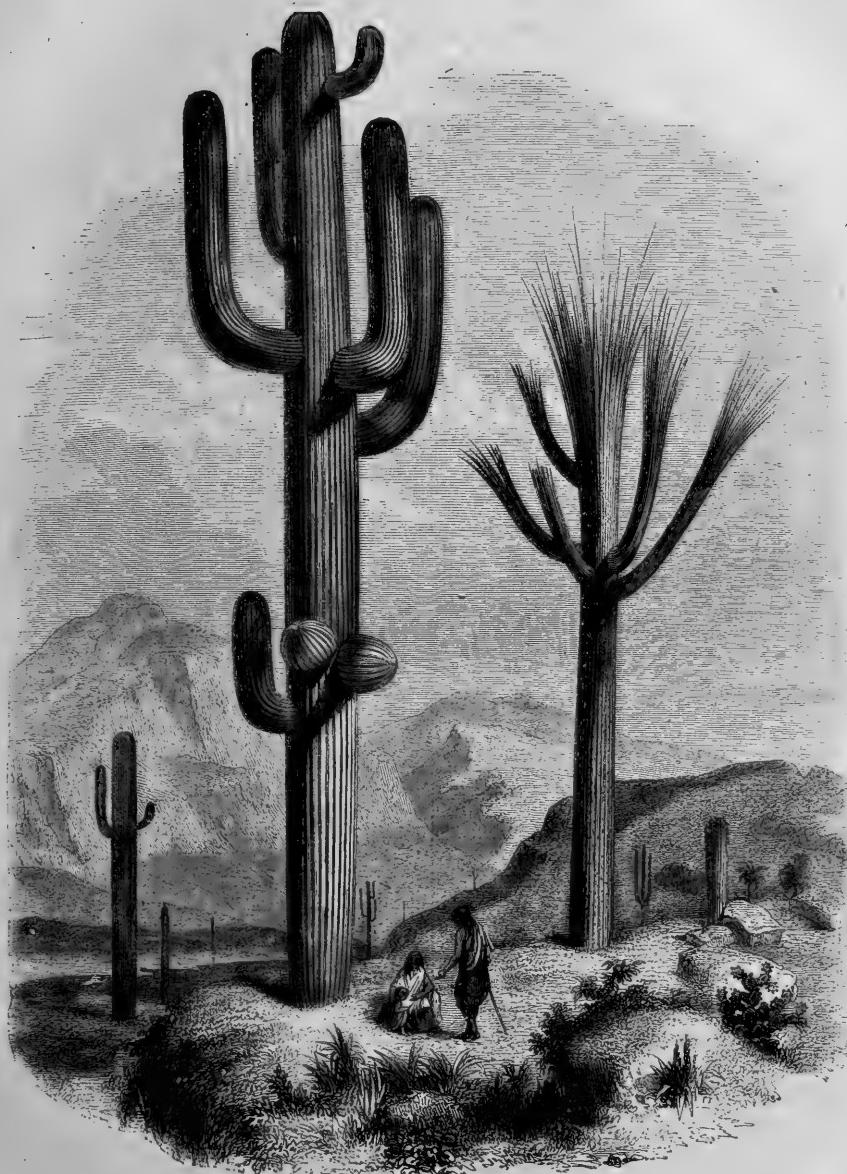

But it is time to analyse the pretty floral landscape illustrated above. If as a mere engraving it is very pleasing, which cannot be denied, what must be its increased charm in reality, invested with all the beauties of colour and the ever-varying fascinations of sunlight and shadow? The greater number of the flowers introduced to produce the effect are perfectly hardy—some are even called weeds—not even excepting the regal foxglove, which French landscape-gardeners treat as a "flower," using it profusely with the richest and most happy effect. How grandly its acuminating spikes of flowers tell out against a mass of dark-green foliage in our engraved picture, and how happily the character of the drooping flowers contrast with the aspiring boldness of the great white lily blossoms, the very queens of a tribe that Linnaeus unhesitatingly designated "the aristocracy of the floral kingdom"! A great

soils specially suited to each individual plant. Even here however, we should find little difficulty with our mixed border of noble hardy flowers, if we thoroughly prepared the ground at first.

ASPECTS OF VEGETATION.

MEXICAN CACTI.

AMONG the many wonders to be found in the vegetable kingdom, few have attracted more attention than the Mexican cacti. Some of the species are so small as to be scarcely noticed as they grow in the sand-or crevices of rocks, while others assume the giant proportions of our largest forest trees, rising perpendicularly to the height of fifty or sixty feet. Truly, nature seems fond of contrasts, or why should we get such gigantic productions as the great leafless cacti of Mexico? one of the most grotesque of which—the *Cereus giganteus*—is represented in the accompanying illustration. There they stand, having more the appearance of fossil trees than the

ASPECTS OF VEGETATION.—TREE CACTI IN NEW MEXICO. (THE CEREUS GIGANTEUS.)

living vegetation of a district. Widely different is the scene we now represent from that of the Brazilian forest which we gave the other day. There the vegetation abounds in graceful beauty. Here we have it stiff and formal, though still rich in interest. The *Cereus giganteus*, the most prominent figure in our sketch, was discovered by Dr. Engelmann a few years ago, who speaks of it as follows:—"As far as the eye can reach, in the valleys or on the mountains, little else but rocky boulders and the stately yet awfully sombre aspect of the *Cereus giganteus* can be seen." This *Cereus* grows very high, branching at intervals; the spines are nearly white and very sharp. When the plants reach a certain age, which is said to be between two and three hundred years, they die and are dried up by the sun, when they split and fall to pieces. Many sorts of dwarf cacti also grow in the same district, as *Echinocactus californicus*, a plant with very strong hooked spines, said to be eaten by the inhabitants; and many *Mammillarias* and *Opuntias*. These dwarf varieties, though not so conspicuous as the larger kinds, nevertheless make their presence known quickly when one comes in contact with them. The giant *Cereus* is the most striking of the genus. It is a native of the hot, arid, and almost desert regions of New Mexico, extending from Squora, in lat. 30° N., to Williams' River, in lat. 35° N., and is found growing in rocky valleys and upon mountain sides, often springing out from mere crevices in the hard rock, and imparting a singular aspect to the scenery of the country, its tall stems with upright branches looking not unlike telegraph posts. While young the stems are globular, becoming gradually club-shaped, and ultimately cylindrical. They are most frequently unbranched, but some of the older ones have branches which issue at right angles from the stem and then curve upwards and grow parallel with it. The stems are gradually ribbed or fluted, the ribs varying in number from twelve to twenty, and have, at intervals of about an inch, thick yellow cushions bearing five or six large and many smaller spines. The flowers are produced near the summit of the stems and branches, and are about four or five inches long by three or four inches in diameter, having light cream-coloured petals. The fruits are about two or three inches long, of a green colour, slightly reddish at the upper end, and oval in form, having a broad scar at the top caused by the flowers falling off; when ripe they burst into three or four pieces, which curve back so as to resemble a flower. Inside they contain numerous little black seeds embedded in a crimson-coloured pulp of a sweet but rather insipid flavour. The Pinos and Papagos Indians, who eat the ripe fruit, gather it by means of a forked stick tied to the end of a long pole. This species of cactus is of very slow growth, judging from the progress made by young plants raised from seed brought from Mexico.

J. CROUCHER.

THE ARBORETUM.

PRUNING CONIFERS.*

DEODAR PRUNING.

THERE are but few species of coniferous plants on which I would recommend the knife to be used. The Deodar is the one on which I most frequently operate. Other species, however, that have been subjected to knife-pruning will hereafter be given. Many individuals are still sceptical about the pruning of the Deodar or any other coniferous tree; one thing, however, is certain, that in not one instance out of the many thousand Deodars pruned in the various parts of the country have I seen any bad effects produced. Pruning no doubt alters the appearance of the trees; but seedlings, when left to themselves, often produce numerous branches, and many of them have a tendency to become leaders, and this often to such an extent that plants six feet in height frequently measure sixteen feet in circumference, and are furnished with twenty or thirty leaders. I generally shorten the branches of such plants so as to give them a pyramidal shape, leaving the strongest or most direct leader, and cutting off all the minor ones. When this is done it will be found that the leader left will go on elongating, and the cut branches will begin to ramify.

Previous to the time when seeds of Deodar were sent to this country in abundance, young plants were extensively propagated by means of cuttings; such cutting-made trees are easily recognized

even at the present time, although twenty to twenty-five feet in height, by their horizontal and somewhat sparse branches, more resembling those of the cedar of Lebanon than the Deodar, and many botanists allege that they are one and the same species. Nearly all the cutting-made Deodar trees suffered from the severity of the winter 1860-61, although the tree from whence the cuttings were taken was not in the least injured. This tree, in the Edinburgh Botanic Garden, is now above thirty-five feet in height. It was of necessity severely branch-pruned during the year 1856, from the circumstances of the branches interfering with the walks on each side. The tree, after being operated on, was made to assume a pyramidal shape, and most of the lower branches cut were fully six inches in circumference. This tree is now in a healthy condition, having a fine symmetrical appearance, and covered with young pendent branches all round, and with a good growing leader. Since 1856, it has been three times slightly dressed all over with a knife. Had this tree not been branch-pruned previous to the snow and frost of 1860-61, it probably would have suffered like all those trees produced by cuttings taken from it, and not previously branch-pruned. Three of the cutting-made trees now exist in the garden, averaging twenty-eight feet in height. They had their branches shortened at the same time with several seedling raised trees, after the large tree just alluded to was found to have sustained no injury. The Deodars raised from cuttings had their horizontal branches shortened from two to four feet off the main stem, beginning at the bottom and tapering upwards. This pruning, no doubt, reduced the strain while the snow was resting on the stump portions of the branches, which, no doubt, proved the means of saving them when all the other cutting-made trees were more or less destroyed.

[The Deodar here seems to be treated as a shrub only; how about the Deodar as a tall and noble tree, beyond the reach of the shears or knife? This was our hope of it.—ED.]

STEM-PRUNING.

A method practised here with many branch-pruned Deodars, but done chiefly for the sake of variety, is the stem-pruning of branch-cut specimens, that is, the removal of some of the lower branches, cutting them off in such a way as to leave fully half an inch of wood close to the stem: such cut points should be smoothed over and darkened with clay. The effect of such stem-pruned Deodars standing on grass lawns is graceful, and where several specimens exist, I would strongly recommend one or more of them to be so treated, as it greatly assists in encouraging an upward growth, besides adding variety to the landscape, and is not in the least injurious to the health of the plant.

Stem-pruning need not be practised on the Deodars till they become eight or ten feet in height, and when of such a size the stem should be divested of its lower branches, ten to eighteen inches from the ground, according to the height of the tree; as the upward growth of the tree increases, the stem-pruning may be carried to the height of twenty-four or thirty inches. The effect of the pendent points of the branches round the central stem, is in some circumstances infinitely more pleasing than seeing the lower branches lying flat on the ground and destroying the grass below.

After pruning the stem of Deodars, as well as all other coniferous trees, where the branches to be removed are in close contact with the ground, it will be necessary to lay down soil, so as to cover any roots which may be near the surface, in order to protect them from the sun or frost. Unless this simple treatment is adopted, stem-stem-pruned trees are liable to sustain injury, and blame given to the pruning, and not to the want of this after-treatment which is absolutely necessary, not only with conifers, but with all evergreen shrubs requiring to be cut down.

The remarks here given with reference to the Deodar all bear upon it as an ornamental tree. Some years ago, seeds were introduced in very large quantities for planting it extensively as a forest tree. This proceeding cannot be answering the end proposed, or we would have heard of it before now. If not succeeding, it cannot be from cold, as we know that the Deodar, under certain circumstances, will endure a great amount of frost.

With stem-pruned specimens of coniferous plants, I consider that the bark on the lower part of the stem, when allowed to mature and harden from exposure, is better able to resist cold, and the tree more likely to stand uninjured than it does when completely surrounded with branches; besides, from the greatest cold being on the surface of the ground, it is more apt to injure those lying on the surface than those higher up, as happened with some plants of *Cupressus M'Nabiana* during the winter of 1860-61, when stem-pruned specimens were not in the least injured, while the unpruned ones suffered severely.

Another circumstance which I have frequently found to affect the health of certain coniferous plants is the alternate frosts and thaws which we often experience, and which was particularly noticeable in

* A paper read before the Edinburgh Botanical Society by Mr. McNab.

many places during last winter, when the ground was frozen hard, and sometimes partially covered with snow. A slight thaw took place, which caused the moisture to rest round the base of the stems, as it could not penetrate the frozen mass. The return of frost at night caused this water to freeze again, and permanently injured the bark on the surface of the ground, and which affected the whole plant. When the bark is thoroughly hardened from frost exposure, such injury is less liable to happen. To prevent as far as possible the occurrence of such accidents, conifers should be planted on somewhat raised mounds if on level ground, while on naturally sloping ground an excess of moisture is less liable to rest round the stems.

The Atlantic cedar (*Cedrus atlantica*) is another coniferous tree which I have branch and stem pruned with success, and it is difficult otherwise to form a well-outlined specimen. With this plant, branch-pruning should be carried on till such time as the top assumes a fair upright growth. When this takes place, commence to stem-prune as recommended for the Deodar, taking care not to cut too close; this stem-pruning to be continued as the tree gets up. Like the Deodar, the Atlantic cedar has a tendency to form several leaders. The superfluous ones ought to be removed when young; but if this has been neglected, several leaders will not be objectionable if they all take an equal and upright tendency—one, however, is preferable.

PRUNING PICEAS.

Of the *Picea* tribe, I have only operated thoroughly on a few species, such as *P. Nordmanniana*, *P. cephalonica*, *P. pinsapo*, and *P. Webbiana*. The first of these is inclined to produce strong side-shoots, frequently stunting the growth of the leader to one and a half inch in height per annum. In some plants, ten years old, now growing in the Botanic Garden, Edinburgh, the diameter of the branches is three feet ten inches, while the height of the plant is only one foot ten inches. I have specimens of the *P. Nordmanniana* raised from seed at the same time, and which have been regularly branch-pruned, which are now four feet in height, showing the propriety of branch-pruning this species at an early stage. Seedling plants of *P. Nordmanniana* rarely put up more than one leader, and it is wrong to allow this leader to be robbed by the superabundant growth of the side branches, now that it is shown that no harm will accrue from a judicious use of the knife. During the period when the *P. Nordmanniana* was scarce, the plants were generally increased by cuttings, grafts, and layers. This pruning was unintentionally the means of causing the leaders of the original plants to assume an upward growth. It is surprising to see many of the early produced plants from cuttings, grafts, and layers, although eighteen or twenty years old, growing procumbent, and, if upright, somewhat fan-shaped. The only way to induce a leader on such plants is to cut off all the branches and peg the stump firmly to the ground. By this means, one, two, or more leaders will be produced from the lower part of the stem. By the removal of all but one, it will in time become a well set leader, and ultimately make a vigorous tree. The leading shoots removed will make excellent cuttings or grafts, by retaining their leaders, which is not the case with the points of side branches. The same remarks are, I find by experience, applicable to many other species of the *Picea* tribe when produced by cuttings and layers, such as *P. nobilis*, *P. robusta*, *P. amabilis*, *P. grandis*, *P. pichta*, &c.

THE DOUGLAS FIR.

With the Douglas fir (*Abies Douglasii*) the case is totally different. Previous to the time when seedlings of this tree were freely produced from the early imported specimens, the Douglas firs were all struck from cuttings, generally taking the leaders from sides or secondary branches. This propagation by cuttings was carried on with vigour for many years, indeed till such time as some of the original imported trees produced cones, and from that period few or no cuttings have been made. Cutting-stump plants from the original trees were very extensively spread over the country, and many of them are now handsome and well-shaped trees. Some of these are at times unwittingly passed off for early seedlings of British-grown trees, and from this circumstance a good deal of discussion about the deterioration of British produced seedlings, as compared with imported ones, has arisen. I am still of opinion that seedlings taken from the earliest cone-producing trees are very inferior to seedlings raised from cones received from their native habitats. All British produced seedlings are easily known from the profusion of resinous blisters all over the surface of the bark, and the naturally light coloured tint of the foliage. The blisters alluded to are not confined to British seedlings but are also found on some delicate foreign seedlings; which is perhaps the cause of their early stunting and the coning of some trees. For my own part, I would not give one cutting-made plant taken from the Bolwood A. Douglasii at Perth (and from which many thousand cuttings must at one time

have been taken and struck) for any amount of plants produced from the early coning trees. The case, however, is different with seedlings taken from cones produced now for the first time by any of the original imported plants. One of these original trees known to me produced its first cones two years ago. These seedlings are totally different from those produced by the early coning trees, being darker in foliage and of slower growth. To my certain knowledge, many of the original seedlings produced by Lynedoch and Raith aways, where planted in open exposed places, have entirely passed away, while of those planted in close shady woods, many still exist and appear to thrive.

PRUNING FOR LEADING SHOOT.

A common occurrence with some species of *Picea* is the tendency to produce double leaders; when this is the case the weaker one can be removed without injury to the plant. I have frequently noticed the destruction of the main leading shoot, caused either by birds, wind, accident, or mischief, and the result has been that the upper whorl of horizontal shoots all gradually assumed an upright habit. It will be necessary to remove all but one, fixing on the strongest, which will be found to have more of an upright tendency than the others. This shoot will gradually bend over the point where the original leader grew, and although slightly curved in the middle, the top will finally assume an upright position, and this, without any necessity for tying. From this branch-made leader the whorls will be produced year by year, with perfect regularity. In the case of the crown of the leader only being injured, all the incipient side buds on the portion left should be picked out except the one nearest the top; but if the top one is not strong, remove a portion of the injured leader till a vigorous one is reached (judging of this before the incipient buds are picked out). The upper one left will soon form an upright leader, and in a few years will completely obliterate all traces of injury. *Picea lowii*, *P. cephalonica*, and *P. pinsapo* are also wonderfully improved by branch pruning, particularly when growing in soils and situations different from what they are accustomed to in their native homes. Growing on limestone rock, which is the case in their native country, it will be found that, in all similar situations in Britain, these trees generally become vigorous and fine shaped.

TAXODIUM, WELLINGTONIA, CYPRESS, AND PINE.

Taxodium sempervirens is another conifer which stands the knife well; its outline will be greatly improved both by branch and stem pruning. The *Taxodium* is not so extensively cultivated as it ought to be. If properly attended to by judicious pruning it will become in many parts of England an excellent avenue tree, but the condition in which it is generally seen, renders it rather forbidding than otherwise.

Wellingtonia gigantea, whether produced from seeds or cuttings, if growing on good soil, naturally assumes a pyramidal shape. Branch pruning is not therefore necessary except in the case of a stunted specimen or a wayward branch, as occasionally happens. *Wellingtonias*, however, may be stem-pruned with impunity. Where many specimens exist, it will be noticed that the upward tendency will be greatly improved by such treatment.

The Cypress *Lawsoniana* is another plant which I have no hesitation in freely stem-pruning, but not side branch-pruning. In its natural state it grows to the height of 100 feet, but when cultivated in this country it has often a tendency to assume the habit of the Chinese *Arborvitae*, by putting out numerous upright stems from the surface of the ground, which in many cases finally stunt what is intended to be the leading shoot. I first commenced the stem-pruning of the *C. Lawsoniana* during the year 1865, and the progress the stem-pruned plants have made over the unpruned is quite remarkable, and, like the Deodar, totally altering the character of the plant.

Of the genus *Pinus*, with the exception of *P. excelsa*, no other species up to this time has been pruned by me, except the removing of any unsightly branch when interfering with a neighbouring specimen. The *Pinus excelsa* when left to itself has rather a sprawling habit of growing, the branches in most cases being widespread, to the detriment of the leading shoot. Trees of *Pinus excelsa*, have been branch pruned here, more or less, for the last twenty-five years. Such plants so treated have now assumed the habit of *Pinus cembra*. The *Pinus excelsa* is rarely asked for by cultivators; but if planted and treated as recommended, it will prove an ornament to the pinyon or shrubby, its long light-coloured leaves contrasting admirably with the foliage of the generality of the dark leaved pines.

When pruning coniferous trees, I generally commence during the month of August, and continue the operation till the middle or end of October. Some have been pruned as late as December and January without any apparent injury, but this may depend on the

effect of the weather, particularly frost, on the new cut extremities. As a general rule, I prefer the earlier months stated.

Conifers in a state of nature are rarely seen as we are accustomed to look upon them in gardens and pleasure grounds. They are generally in large forests, where, from their proximity, the lower branches generally get destroyed, and from this circumstance the trees must of necessity assume an upright habit. It is therefore incumbent on us to take steps in order to imitate nature, and thus induce in some plants a tree growth, instead of a bush form, which is not their natural condition.

THE Araucaria.

Certain coniferous plants are not in the least injured by a free use of the knife, while with others, it is well known that they will not stand it in the slightest degree. The Araucaria is very susceptible of injury if its juices are interfered with, either by cutting or bending, and I feel almost persuaded that the excessive injury done to the Arancaria during the severe winter of 1860-61, was in a great measure due to the excessive bending of the points of the branches under the weight of snow which prevailed at the time, thus rupturing the upper tissues close to the stem, and thereby exposing them to the severe frost which at that time prevailed, aided, no doubt, by the long continued moist autumn which preceded. Injury is often wrecklessly done to the tops of Araucarias by breaking them off, as is well known to the cost of some nurserymen. With such mutilated plants, one of the side shoots composing the upper whorl is not unfrequently tied upright so as to form a leader. Instead of tying up one of these side branches, a slight bending down of the upper whorl of branches is preferable; by doing so, two or more leaders will be produced from the centre. The superfluous ones are to be removed, not by direct cutting off, but by twisting a piece of very fine wire tightly round them, leaving the strongest one untouched. This wire will cut them through in a short time; they can then be removed without injuring the plant. The shoot unwired will soon become a good leader. If a leader is ever formed by the tying up of a side branch, it will be difficult for such a plant ever to assume a uniform shape.

THE SHAWDON HOLLIES.

THESE deserved to be associated with the big and beautiful trees to which you have lately directed attention. Shawdon Hall lies about seven miles north-west of the ancient town of Alnwick, in the lovely Vale of Whittingham, and owing to its somewhat secluded situation, these beautiful hollies are little known beyond the neighbourhood in which they grow. They stand in two parallel rows, running north and south, about eighty yards in length, and about twelve feet apart, the trees originally, apparently, having been planted about ten feet asunder in the rows. Several of them are now wanting, having been blown down at different times by high winds.

The row facing the west is composed principally of the golden-edged holly. One of the largest of this variety measures six feet two inches round the bole at four feet from the ground. The height of this tree is forty-five feet; all the others of this sort are about the same height. The row facing eastward consists wholly of the common green holly, and has the advantage over the variegated trees of a few feet in height, and of possessing more bulk of timber in the boles, which are bare of branches to a considerable height. Their great, heavy tops are swayed in all directions, and amongst them are several specimens of natural inarching. Two of the trees, at thirteen feet from the ground, are joined together in most perfect union, the stem of each being free from branches below the point of junction. This intimate union and callusing together lasts for about two feet, then they branch out into a fine head. In the top of another large tree there is a perfect union between two large limbs, the only thing remarkable about which is, that a third branch has become imprisoned, and so fixed into the point of union as to lie across the two principals, somewhat like the transverse beam of a cross.

I may remark that the last tree, at the northern end of each row, is a fine yew. The southern end of both rows is occupied by a noble pine (a real Abernethy, a local variety of *Pinus sylvestris*), which, at two feet from the ground, measures nine feet three inches in girth, and at five feet, eight feet four inches. As near as can be calculated, there is about seventy-five feet or eighty feet of saleable timber in the bole of this tree.

My first impression with regard to these fine hollies was,

that they had been planted with the intention of forming a walk or avenue to an old keep; but, the fact of the pine-tree to which I have referred being planted right in the centre of both rows, makes this supposition untenable, for, had the pine been planted there after the walk was no longer wanted, the hollies must be of very great age indeed. Upon the whole, I am inclined to think that both pine and hollies are coeval. The row of green hollies has probably been planted as protection from the east winds, and as shelter for the golden-edged ones. The yews at the northern end serve as a shelter from the northern blasts. The pine may have been a rarity, as we have only four trees of this variety in the park, all planted, seemingly, at the same time.

There may be many larger holly trees dispersed over this country than the Shawdon Hollies, but I question if there is so striking a group to be found anywhere else. When the lawn is covered with snow, the variegated trees form quite a picture, that, once beheld, is not soon forgotten. Their pendulous branches of green and gold are set off in what appears, at a little distance off, to be a framework of dark olive green; for the branches of the common hollies, laden with crimson berries, overtop them by a few feet.

I am unable to form any conjecture regarding the age of these fine hollies; but, judging from the appearance of the golden-leaved variety, they are destined to be trees of beauty when the green trees are no longer to be seen.

I have thus minutely described these lovely trees, in the hope that planters may be induced to use them more extensively than has hitherto been done; for, if planted with care and judgment, they will leave behind them a monument of beauty "that will be a joy to generations yet unborn."

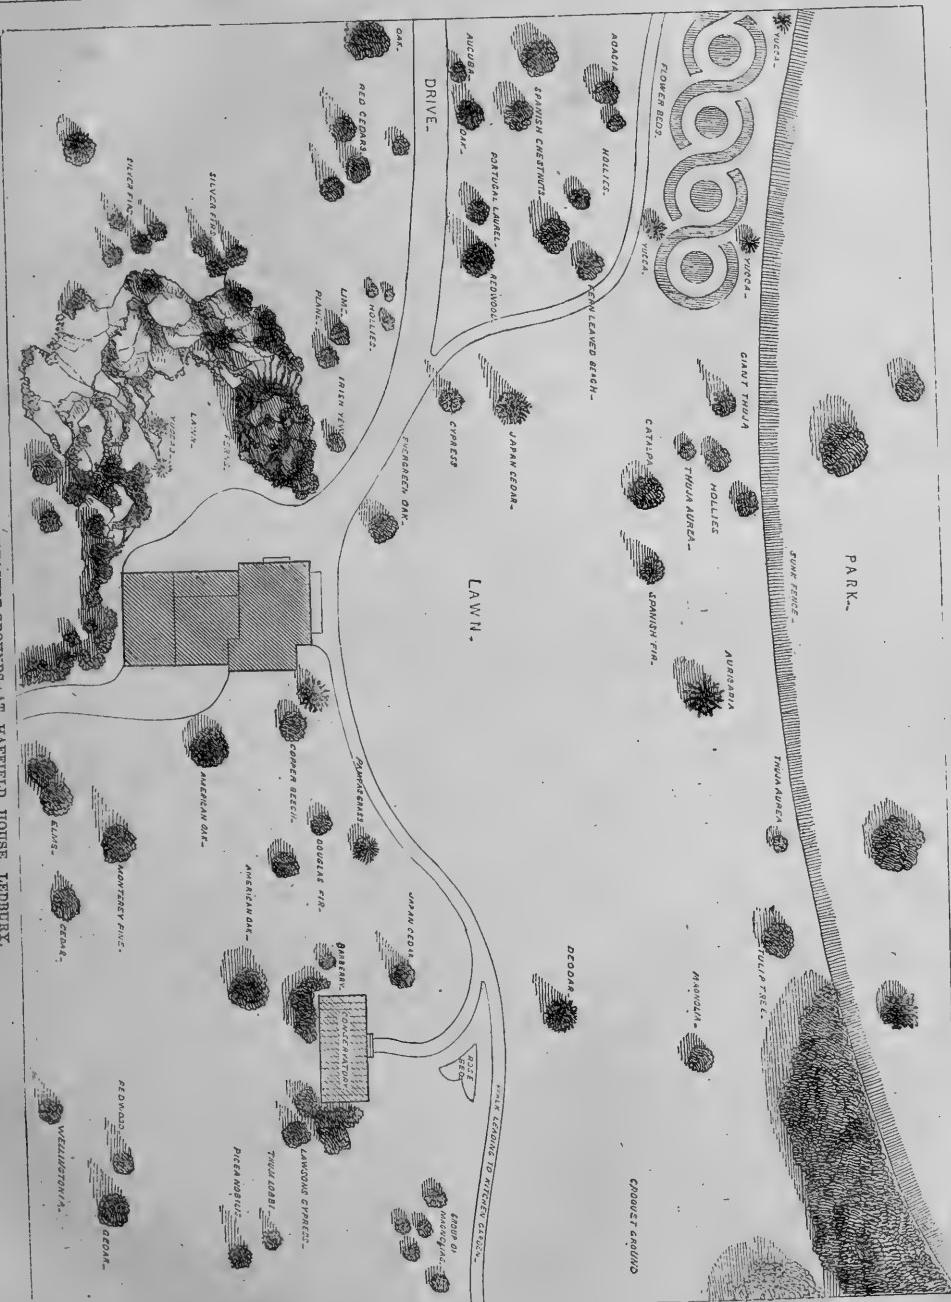

JAS. THOMSON.

GARDEN DESIGN.

THE GARDENS AT HAFFIELD, LEDBURY.

THE garden, a portion of which we this week engrave a plan of, is chiefly distinguished by the presence of the nobler members of our garden flora. It is the reverse of the system now so often seen, of placing the beds for summer flowers in crowds near the house. By this plan, we usually get formal masses of wet mould in winter, and very little else. Of course, the presence of such a noble series of plants and trees as those shown in our plan does not prevent the fullest justice being done to the flower garden. In a larger place, it would be desirable to preserve a little more breadth around the house; but this is a point which must be regulated entirely by the size of the place and local circumstances.

The drive from the principal entrance on the Gloucester Road leads through a well-timbered park to the mansion; the latter is situated in a valley, with gently sloping banks rising gradually on the north and north-east side, clothed with forest trees in great variety, which afford good shelter. The aspect of the house is nearly south, and from some of the principal rooms a good view of the neighbouring hills is obtained. The pleasure-ground is about ten acres in extent. On the east side of the house is the entrance, in front of which, at some little distance, the sloping bank has been cleared of soil and débris, so as to form a rock-garden, clothed with suitable plants and shrubs, such as Yuccas, Araucarias, alpine plants, ferns, and creepers. The peculiar beauty of this garden cannot be well given in a bird's-eye view. It rises to a height of thirty-five feet, and forms a good contrast to the other parts of the grounds. On the south side of the house is a nice piece of sloping lawn, kept entirely free from geometrical disfigurement in the way of flower-beds. On this stands a fine Araucaria that was planted in 1842, and which now measures thirty-two feet in height, and bears cones every year. The girth of the trunk of this tree at a foot from the ground is four feet two inches. A fine cedar may also be found here that was planted in 1852, and which is now forty-five feet high, with a trunk six feet in circumference at a foot from the ground; likewise two Cryptomerias, planted at the same time, thirty feet high, with stems four feet in girth; an *Abies pinsapo*, *Thuja aurea*, and other fine coniferous plants.

PLAN OF THE PLEASURE-GROUNDS AT HAFIELD HOUSE, LEDBURY.

Between the house and conservatory stands a remarkably fine Douglas fir; seventy feet in height.

The following were lost during the severe winter of 1860-61, viz., *Pinus insignis*, forty-five feet in height; *P. macrocarpa*; *P. patula*, twenty feet in height; *P. Sabiniana*, *Cupressus Lambertiana*, and many others.

A group of Magnolias, consisting of the following kinds, viz., *acuminata*, *conspicua*, *macrophylla*, *tripetala*, *Thompsoniana*, and others, is an object of interest to visitors; who also find much to admire in the way of hardy trees and shrubs of different kinds, growing singly and in masses, as notified in the plan, in which the names of the fine specimens of Araucaria have been omitted by our draughtsman.

THE BOTANIC GARDEN, REGENT'S PARK.

I AM glad you have given a plan of this really tastefully laid-out garden—so far as essentials are concerned. If any person doubt what may be done by tasteful planting, I know of no place where he can have his doubts removed so soon as in these gardens. Originally a flat, this ring of ground has been made to look as sweetly diversified as any rural spot; but it is not its diversity I so much wish to call attention to, as the artistic way in which the slender belt of boundary plantation is managed; so that the garden merges into the surrounding scenery imperceptibly, and looks far more extensive and refreshing than if planted after any fashion of formal planting whatever. What a pity it is that in nearly all our great public gardens there is scarcely any trace of good design!

H. Viner.

THE FRUIT GARDEN.

WALL TREE PROTECTION.

We place trees against walls that they may derive more heat, and to do so we incur a great deal of expense and trouble; but after all this is done, we very often fail to give them the most necessary of all attention—protection when in flower. Hence fruitless walls and empty fruit rooms. Depend upon it, the chief of the evils from which our fruit trees suffer is lack of temporary protection in spring, when leaves and flowers and fruits are young, tender, and perishable. Frost is almost as antagonistic to these as is the rising sun to the dew drops. A few mild and sunny days occur in spring; the flowers open, and the little leaves "put forth their hands into the ray," when suddenly a sharp frost comes and takes all parts in its grip; the rising sun throws its rays right against the frozen tree before it has had time to thaw, and then farewell to the flowers and fruit for one year, or perhaps the health of the tree for life. You may drain as well as it is possible to drain; you may choose the best soil, the best kinds, the most suitable stock, and prune at all times on the best methods; and yet little but disappointment and disaster will occur unless effectual means are adopted to protect the trees from their chief enemy in our changeable climate—severe frosts in spring. Doubtless the process is the cause of some little trouble as a rule; but as it is frequently a matter of crop or no crop, a little consideration should convince us of the necessity of perfect protection to the flowers in spring. It is true protection is often so badly given that no better result is attained than by leaving the trees fully exposed on the walls; but if they are well protected there can be no doubt that we may gather as full crops and as fine fruit as could be desired.

When the changeableness and severity of our climate are considered, it is astonishing how few and insignificant are the means taken to protect the trees. One of the first considerations in growing fruit trees out of doors should be the providing of an efficient coping or projection of from six inches to ten inches, at the very top of the wall, to throw off cold rains, sleet, and to a considerable extent protect from frost itself. This coping may be made of bricks, though not very effectively, of cement or concrete, of slate, tiles, thin stone, or any like materials. If it were merely to throw off to some extent the destructive rains of hail and sleet, it will be generally admitted that this is a good and simple protective agent; and yet we see peach culture attempted without a particle of coping in many gardens abundantly supplied with means and labour.

In such cases the tree is really as much exposed to danger as it would be away from the wall: it gets more heat afterwards, but the main point is to secure the setting of the crop. However, many take care of their walls, as regards the short permanent coping, but in very few gardens do we see an attempt at a much more desirable kind of protection—a wide, temporary coping throughout the time when the trees are in tender blossom, or likely to incur the least danger. This would effectually throw off frozen rains, prevent radiation, and, except on walls facing the east, suffice to guarantee a crop and the health of the trees. This temporary coping should be about eighteen inches wide, and made of light wooden frames covered with tarpaulin. Wooden shutters may also be used; but the light, cheap frames covered with tarpaulin are undoubtedly the neatest, lightest, and, after all, the cheapest things that can be used for this purpose. They should be placed under the permanent coping.

By placing iron rods under the permanent coping, with a slight turn up catch at the end, at about five or six feet apart, these temporary copings may be slipped into their places and firmly fastened there till all danger is past. This may seem a good deal of trouble to take with wall trees; but when it is considered that efficient protection of walls would save us from building houses for hardy fruit, nobody should begrudge the attention. When once you build houses for growing hardy fruit, there is no knowing where the expense may end. Fire heat, repairs, daily care, both for ventilation, watering, and the numerous attentions that houses require, soon run up a bill to which any expense devoted to outdoor fruit-growing is insignificant. The reason why the temporary coping advocated is so desirable is that it protects the trees efficiently when they most require it, and does them no injury at any other time. If a too deep permanent coping be adopted, it has some disadvantages: it prevents the trees being washed by the refreshing rains of summer, and, by depriving the upper portion of light, prevents growth—unless that coping were of glass fixed in a light and cheap iron frame; and why should it not be so? Under a very deep permanent coping the trees refuse to grow to the top of the wall, but keep a respectable distance from it; but the moment the temporary coping is removed, the foliage more immediately under gets full light and air, and perfect development over all parts of the wall is the result.

In cases where this wide and excellent temporary coping is not adopted, and, indeed, sometimes where it is adopted, it is desirable to screen the face with cheap canvas or woollen netting, hung so that it may be moved to and fro at pleasure. A temporary coping of glass is perhaps better than any, but it should be removed when danger of frost is past. When danger is past, canvas or netting and their appurtenances should be carefully dried, and stored for another year, as should the tarpaulins before alluded to. In cases where none of these protecting agents can be spared, some good may be done by merely placing the boughs of any evergreens to be easily spared among the flowering spray of the wall tree. These will protect from the cutting blast, and even from frost, to a much greater degree than might be supposed. But let it not be supposed that any protection is really efficient which does not protect from rain during the period of flowering. It is not that rain itself kills, but if tender young leaves and flowers are saturated with rain they are then thoroughly prepared to be quickly encased in ice.

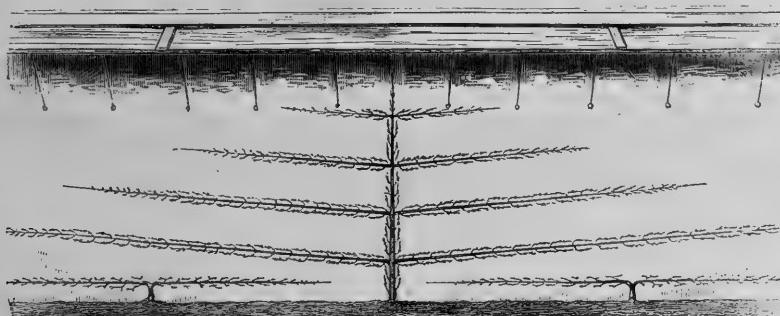

There is another sort of protection on which I should like to say a few words—guarding the trees against the effects of very severe frosts before the flowers open, and when they are generally supposed to be perfectly safe. It used to be a practice, and indeed it still is here and there, to expose both vines, peaches, nectarines, &c., in houses to the action of the frost in winter. The houses used to be stripped for that purpose. I have lived a long time in gardens, and more than once have seen much mischief done in this way. After the severe frosts of 1813-14, 1821, and 1837, I witnessed much destruction from the killing effects of frost on the wood. The trees perished altogether, or only existed in a ghostly state. The vine succumbs to a milder degree of cold than the peach or nectarine, but we now and then have frosts which destroy even these, and in my opinion these very severe frosts ought to be guarded against. Of course nobody would now willingly expose house trees to the frost, but those on walls are invariably exposed. Now it

occurs to me that if some efficient covering were placed against them, when once the wood is well ripened, it would entirely prevent frost from injuring them during the severest seasons, and might in all prove useful in retarding the bloom. The kind of covering is not so easy to determine. Nothing should be used that would encourage vermin near the trees. I would remove it when the opening flowers imperatively demanded it, and not before. Rough wooden shutters would probably be the best things, and they might be utilised for other purposes once the trees began to flower. Of course I would not recommend this in districts where the peaches and nectarines were never liable to be injured by frost; but, as I have several times seen fine peach walls utterly ruined by a hard winter, I trust I shall not be considered fastidious or unpractical for recommending that they should be saved from such a disaster, as well as from loss of crop and health by spring frosts. Protection given to guard the trees themselves against severe frosts, would have the good effect of keeping them dormant till a later period, an advantage of course. Our illustration shows the careful way a skilful market-grower at Montreuil protects his peaches in early spring by means of temporary and wide wooden copings. The form of tree may seem strange to many, and the wall may seem very bare; but in early summer the whole will be well covered by the numerous shoots sent out by the rather closely pruned shoots of the past year. If these walls were deprived of this simple and capital temporary protection the crops would be invariably lost.

J. B.

"Oh, but," exclaims Mr. Straightedge, "who could have a lot of nasty straw littering about his garden?—it would be an intolerable nuisance." Well, just so; but, so far as the future is concerned, that sword has two edges. With those who have thought upon the subject, the opinion very generally prevails that the union which has so long existed between the fruit and the vegetable garden should be dissolved. The proper growth of the latter is certainly inimical to the cultivation of the former, the deep digging and rich manuring necessary for vegetables being decidedly injurious to the cultivation of a large proportion of fruit trees; therefore, I say, have your cabbage garden in any sheltered and convenient place where the deep and highly enriched cultivation so necessary for perfect success may be carried on, without injury to anything, and place your fruit garden so that it shall form an integral and important element of the ornamental grounds. Here concentrate your glass erections, forming them, if need be, so that they may afford a continuous promenade, whereby in the coldest day in winter the "tour round my garden" may be made with ease and delight. Instead of suspending for the questionable shelter of a dreary quadrangle of perpendicular walls for your fruit trees, place them under glass, through the transparent walls of which the adjacent garden may be surveyed. Of course, I shall be told the fruit crops even in glass houses fail sometimes. Yes, and so do all mundane things; but, properly understood and managed, the climate of Madeira or the South of France under glass will be more likely to ensure regular crops of fruit than the exposure of a tree to the pitiless pelting of the storm upon a wall outside. Upon this I think there cannot be a second opinion.

W. [We quite disagree with our correspondent, one of the best prac-

Peach Tree at Montreuil, under a Wide Temporary Wooden Coping.

AN ENEMY TO WALLS.

cas GARDEN WALLS are things of the past—ugly and needless incum-Morances of the ground, which ought not to be tolerated except in some outlandish wild where evergreen trees will not grow. In such a place there may be an excuse for walls; but, associated with a modern mansion, I can only regard walls as a relic of the barbarous ages in horticulture, when glass, if not unknown, was little used. If you talk of early crops, I point you to those gardeners who supply the markets of London and other centres of population; they get little aid from bricks and mortar, and yet their crops are ready for the market, and early peas are down to 9d. and 1s. per peck almost as soon as the walled garden begins to afford the first dish. Of course, I am aware that only special and favoured localities can do this early work; but they do it by the acre and by the field, while we "lesser men" are raising a single row or two. The aids to cultivation which the market gardener brings to bear upon his produce, quite independently of wall protection, are quite worthy of serious study, and, attentively examined and described, would form a most interesting handbook on the production of early crops. Look at the manner in which he throws his ground into narrow ridges, sloping to the south or south-west, planting or sowing on the sunny side, where the crop is of course protected from those prosecuting "north-easters." See again the acres of radishes, rhubarb, early potatoes, &c., that are nightly sprinkled over with clean litter, to be cleared away the next morning. Observe the almost perpendicular ridges upon the top of which tomatoes are planted and trained downwards, and produce splendid crops, when the operator in a walled garden is complaining of the unfavourable season and his tomatoes not ripening.

tical gardeners in England, as to the value of garden walls. Even if all lovers of a garden could erect orchard houses by merely wishing for them, garden walls would yet have their important uses in all parts of these islands.]

INFLUENCE OF VIOLET LIGHT ON VINES.

In April 1861, cuttings of vines of some twenty varieties, each one year old, of the thickness of a pipe-stem, and cut close to the spots containing them, were planted by General Pleasonton, of Philadelphia, in the borders inside and outside of a grapyery, on the roof of which every eighth row of glass was violet-coloured, alternating the rows on the opposite side. Very soon the vines began to attract notice from the rapid growth they were making. Every day the gardener was kept busy in tying up new wood, which the day before had not been observed. In a few weeks after the vines had been planted, the walls and inside of the roof were closely covered with the most luxuriant and healthy development of foliage and wood. In September of the same year Mr. Robert Buist, from whom the General had procured the vines, visited the grapyery. After examining it very carefully, he said:—"I have been cultivating plants and vines of various kinds for the last forty years; I have seen some of the best vineries and conservatories in England and Scotland; but I have never seen anything like this growth." He then measured some of the vines, and found them forty-five feet in length, and an inch in diameter at the distance of one foot above the ground. And these dimensions were the growth of only five months!

In March 1862 they were started to grow, having been pruned and cleaned in January of that year. The growth in this second

season was, if anything, more remarkable than it had been in the previous year. Besides the formation of new wood, and the display of most luxuriant foliage, there was a wonderful number of bunches of grapes, which soon assumed the most remarkable proportions—the bunches being of extraordinary magnitude, and the grapes of unusual size and development. In September, when the grapes were beginning to colour and to ripen rapidly, Mr. Buist visited the grapey again, and estimated that there were 1,200 pounds of grapes.

During the next season (1863) the vines again fruited, and matured a crop of grapes, estimated, by comparison with the yield of the previous year, to weigh about two tons; the vines were perfectly healthy, and free from the usual maladies which affect the grape. Many cultivators said that such excessive crops would exhaust the vines, and that the following year there would be no fruit: as it was well known that all plants required rest after yielding large crops. Notwithstanding, new wood was formed this year for the next year's crop, which turned out to be quite as large as it had been in the season of 1863; and so on, year by year, the vines have continued to bear large crops of fine fruit without intermission for the last nine years. They are now healthy and strong, and as yet show no signs of decrepitude or exhaustion.—*André Poëy, Paris, in "Nature."*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Select Pears.—Will you kindly give me the names of a few really good pears suited for our climate, a choice selection from the many score kinds grown?—E. S.—[The following are best calculated to suit the London district; they are arranged in the order of their ripening. Mr. Ingram's selection, in a recent number of *THE GARDEN*, will suit more northerly and cooler districts. Other situations may have other wants:]

- | | | |
|--|-------------------------------------|---------------------------------------|
| 1. Doyenné d'Été, July | 10. Flemish Beauty, Sept. | 18. *Doyenné du Comice, |
| 2. Jargonne, Aug. | 11. *Mari Louise, Sept. | Oct., Nov. |

Those marked * will grow larger and handsomer against a wall, but will be better flavoured (if smaller) if grown in the free air. Marie Louise will do as a full standard; the others as low trees only, pyramids, or trees on trellises.]

Grapes in Bottles (see p. 189).—Will Mr. Tilley oblige by telling us what size bottle he uses for this purpose, and the average temperature required? Would a dry cellar, or an upper room in a loft, answer? Are the bottles corked, or left open at the mouth?—W. H.—[The bottles used here are about three inches in diameter at the bottom, and ten inches in height, made of clear glass, and will contain nearly a pint of water. At first I used pint porter bottles, and they answered very well; but this year clear glass bottles are used, on purpose to see if the water is clear, as small pieces of charcoal are put in the bottoms of the bottles to keep the water sweet and clean. The temperature of the room must be kept as low as possible, just to exclude frost in severe weather, and never to get higher than 50° when the weather is dry and open. This could be best attained in an upper room in a loft, where proper ventilation could be given in dry days, and where a fire or fire could dry the damp in wet weather. The bottles are not corked, but left open at the mouth.—WILLIAM TILLEY, *Welbeck*.]

Fruit on Railway Embankments.—We noticed in *THE GARDEN* of the 27th ult., an article on railway-side fruit culture, in which it is shown that fruit trees do grow on railway embankments.... Our experience is the opposite. Fourteen months ago we planted one thousand raspberry canes on the side of an embankment, and all of them have died, the reason, in our opinion, being, that they had not sufficient soil in which to take root. It must be borne in mind that such embankments as you mention are mostly composed of sand or gravel, especially in this country. We would like to know if anyone has tried the experiment of growing fruit trees on embankments in Great Britain, and with what result?—M. *Alderman*.—There is abundance of good soil along many of our railways which might be utilised, if not for fruit for some other product of use to the community.]

New Fruit Label.—M. Ed. Pynaert, of Ghent, has just invented a new kind of label for marking fruits. It consists of small squares, like postage-stamps, on which the names of fruits are printed. They are in sheets of fifty labels, which are perforated at the edges like postage-stamps, and, like them, gummed on the under surface. These sheets are either special or general. In the former case, the fifty labels of the sheet all bear the name of the same kind of fruit; in the latter, the labels all bear the names of different kinds. The cost is very trifling: ten labels for a half-penny; a sheet for a penny; one thousand labels, in eighty varieties, or according to choice, half-a-crown.

FOUNTAINS.

We are highly adverse to fountains in gardens of any kind, in consequence of the great expense of constructing and supplying them, and also of the very unhappy effects they often produce from being placed in positions entirely unsuited for them. For instance, nothing can be in much worse taste than the water squirts at the head of the Serpentine; and those in Trafalgar Square, as already noticed in the columns of *THE GARDEN*, are feeble and ineffective. Of fountains out of place, we have recently seen no example worse than that in the centre of the exhibition-tent in the Botanic Gardens, Regent's Park. We think it wrong to place a fountain of any

kind in the picturesque garden, and it is better not to meddle with them in the geometrical one, unless a graceful design and a suitable position for them be secured. Fountains are seen to best advantage in open dusty spaces, small squares, &c., in hot countries. In all cases where expense is incurred for them, concise and well executed designs like the one in the accompanying illustration should be the aim. At the head of the Serpentine, and in many other places we could name, the artist has been ambitious in attempting to make a regular garden of fountains, and the result is poor indeed. Even if there were such a pleasing design as that in our illustration, its effect would be to a great extent marred by surrounding it with a number of meaner ones, and with much rough and unsatisfactory stone and stucco work. We hear with regret that the Metropolitan Board of Works contemplate the erection of a costly fountain in one of the small gardens on the Thames Embankment. To do this would require as much money as would suffice to let the sun and a few green leaves gladden the eyes of the dwellers in some pestilential nook of Bethnal Green. But if people persist in spending money on fountains, they can hardly be excused for making them decidedly ugly when happy examples occur in many not distant cities.

SEED COVERING IN THE AMERICAN'S GARDEN.

If there is one fault above another in all the gardening books, it is the lack of those simplest of directions and suggestions, with which the novice is utterly at fault. Thus, we are told in *why month to sow a particular seed*; that it must have a loamy soil; and are favoured with some special learning in regard to its varieties, and its Linnaean classification. "Pat," we say, "this seed must be planted in a loamy soil." Pat (scratching his head reflectively): "And shure, isn't it in the garden thin, ye'd be after planting the seed?" Pat's observation is a just one; of course we buy our seed to plant in the garden, no matter what soil it may love. The more important information in regard to the depth of sowing it, the mode of applying any needed dressing, the requisite thinning, the insect depredators, and the mode of defeating them is, for the most part, withheld.... That the matter is not without importance, one will understand who finds, year after year, his more delicate seeds failing, and the wild and attentive Irishman declaring,—"And, begorra thin, it's the cold seed." "But did you sow it properly, Patrick?" " Didn't I, faith? I byried 'em an inch if I byried 'em at all!"

An inch of earth will do for some seeds, but for others, it is an Irish burial—without the wake. The conditions of germination are heat, air, and moisture. Covering should not be so shallow as to forego the last, nor so deep as to sacrifice the other influences. Heat alone will not do; air and moisture alone will not do. A careful gardener will be guided by the condition of his soil, and the character of his seed. If this have hard woody covering like the beet, he will understand that it demands considerable depth to secure the moisture requisite to swell the kernel; or that it should be aided by a steep, before sowing. If, on the other hand, it be a light fleecy seed, like the parsnip, he will perceive the necessity of bringing the earth firmly in contact with it.—*My Farm of Edgewood.*

THE KITCHEN GARDEN.

SEEDLING SEAKALE FOR FORCING.

I HAVE noticed that many excellent gardeners practice, and recommend, the plan of propagating this indispensable vegetable by planting pieces of the roots, about two feet apart and the same distance asunder, between the rows—thinning out the thickct of crowns each root is sure to make, to two or three. Later in the season they pick out the seed-stalks, which the latter generally show from time to time during the summer, seldom getting roots fit to force till the end of the second year.

Now, with all deference to the opinions of others, I venture to assert that all this trouble during two years is not needful, not to speak of having to grow two brengths of Seakale—a forcing and succession stock—by the above system. It is a well-known fact that seedlings, as a rule, always furnish the most vigorous plants, and if any one will grow two batches of Seakale—one from chopped roots and the other from seed—I am sure they will verify the truth of this assertion to their complete satisfaction.

Seakale, sown in March or April in well-prepared ground, will yield crowns fit for forcing in November equal to plants from cuttings at the end of two years. I will not say that each seedling plant will furnish as many crowns—not more than one, in fact; but a square rood of seedlings, judiciously cropped and thinned, &c., will yield as many, and as good, crowns as the same extent of two-year-old plants from cuttings. I have sown a pound of Seakale seed annually for these last seven years, and have never failed but once in having an excellent supply of plants, the whole of which have always been forced the following winter and spring. The failure referred to was caused by an overdose of salt administered inadvertently by one of my men.

I am aware that forcing seedlings the first year is not a new plan; but I also know, both from reading and experience, that it is an economical and satisfactory system very rarely adopted; and I wish to convince your readers that they may sow and clear their ground of Seakale nearly within the year, instead of always having two quarters of the kitchen garden occupied by it.

J. SIMSON, Worley.

NEW VEGETABLES OF THE PAST YEAR.

AMONG the new vegetables of 1871 we find new names to be legion. It is, however, always a difficult matter to decide as to what is truly a novelty or new variety, and what is merely a new name given, it may be, to a greatly improved stock, but still essentially the same. Our vegetables are improved, or kept up to the standard, by selection far more than by the efforts of the hybridizer or introducer, as in the case of fruits and flowers. Peas, however, yield us real novelty. Mr. Laxton, to whom we have already been indebted for several important additions, is now about to outdo himself by giving us, all at once, six new varieties—to wit, Superlative, having great pods like a broad bean, fully seven inches in length, which, whatever its quality be, will be a glorious pea for exhibition ; Griffon, early as Sangster's, of a deep grassy-green colour, a great desideratum in an early pea; Popular and Omega, two wrinkled marrows; Evergreen and Conquest, the former a smooth pea, said to be of fine colour when cooked, the latter a green wrinkled. In addition to this, we have Emperor of the Marrows, from Mr. Williams; White Gem, First Crop Blue, from Messrs. Carter & Co.; Best of all (Maclean), from Messrs. Sutton & Sons, which last, if it prove true to its name, will be good indeed. One more must be noticed, viz., Canadian Dwarf, from Messrs. Finney, which is of great promise as an extraordinary cropper, and of fine quality; and there are still more candidates. Of onions we have many claiming notice of late. At present we may allude to the New Red Marzagole, the Neapolitan Marzagole, and the Red Mammoth Tripoli, all very large, of the Tripoli type. Amongst cucumbers there are also many aspirants, but the best which we have seen is Douglas's Tender and True. For the lovers of large cucumbers, we may indicate the Marquis of Lorne. In tomatoes we have gained a good variety in Delfance; as among lettuces we have also in the Kingsholm Cox. In radishes we have a welcome addition to our winter salads in the Large White Californian, no doubt of Japanese or Chinese extraction, introduced by Mr. Robinson, which grows to a large size, resembles a great white Sablons turnip, and is of good quality. Lastly, among potatoes, we

have so many to choose from, that we are at a loss which to select. Lee's Hammersmith Early Kidney is very fine in appearance; but it would be invidious to name others from amongst so many. It is satisfactory to know, and highly gratifying to feel, that the past season, although an unpropitious one for gardening generally, does not show any falling-off in energy amongst gardeners, but a quiet progressive improvement.—*A. F. B.*, in "*Florist and Pomologist*."

AN OLD TEMPLE GARDEN ELM.

THE Benchers of the Middle Temple have just cut down an Elm which was sacred to the musings of Charles Lamb and the kindly fictions of Charles Dickens, for it was under the shade of that tree that "Elia" walked, and that pretty Ruth Pinch kept her tryst with honest John Westlock. Who has not read with a brightened eye and a cheerier heart that chapter which begins, "Brilliantly the Temple fountain sparkled in the sun, and merrily the idle drops of water danced and danced, and peeping out in sport among the trees plunged lightly down," &c.? "A pleasant place, indeed," said Ruth; "and so shady!" Shady no more; there lies the old elm along the side of the Hall, sound to the core. *Cui bono?* The Benchers of our Inn of Court may build halls and pull down old erections, but once cut down a fine old tree, and no man can replace its beauties. Let those who may be misled by the plea that the old tree was dying pay a visit to its mutilated body by the side of the Hall, and observe, at the same time, the gap made in the little community of timber, and then say, as they will do, "Why cut it down; it cumbered not the ground?"—*B. F.*, in "*Times*," Feb. 3rd.

To the above, the following reply has since appeared in the same paper :—

The legal barbarity imputed is exclusively my own. *Audi alteram partem.* The tree was a decaying institution. It had perished at the root, and nodded to its fall. It was condemned to fall, that it might fall safely and not be a fatal tree. I am a planter and not an uprooter and shakers of that which is planted in the soil too well to venture rashly to remove a tree. As to such an one, public opinion would deem him fit to be suspended on a bough of its neighbour tree; but would it very much astonish the writer to hear that in lieu of this one elm half a score plane trees are about to be planted on that spot, and that I hope our venerable buildings, under my renovating hand, which is thought to be the hand of a legal barbarian, will flourish in a green old age? Trees, like men, we all wish to see planted and retained in their proper places. I read that some mischievous persons are destroying the trees on the Thames Embankment. The Commissioners threaten to remove the rest. In mercy, great Commissioners, execute your threat, for instead of the beautiful river, with its moving and sparkling waters giving animation to our thoughts by all it carries on its course—instead of the noble architectural beauties which the sight now takes in—we, if we live so long, shall otherwise see hereafter a long avenue of green foliage, and guess at a river which that foliage hides. Pardon me for this heresy, which, as it comes from a legal barbarian, may possibly be pardoned.—*Laurence Peel, Athenaeum Club, Feb. 5th.*

DAMAGING TREES ON THAMES EMBANKMENT.

At a recent meeting of the Metropolitan Board of Works a report was received from the Parks and Open Spaces Committee, stating that certain of the trees on the Victoria Embankment roadway had been maliciously cut, and recommending the Board to offer a reward of £20 for information which would lead to the conviction of any person damaging the trees. The chairman said he had been to the Embankment to ascertain the facts, and he found that these trees had been deliberately injured, and that it had been done with skill, as some instrument must have been put through the fencing for the purpose of damaging them as much as possible.—*Daily Paper*.

[Our own reporter, who has inspected the Embankment, states that the damage committed occurs in the line of trees next the river. A few yards to the right of Waterloo Bridge, looking towards the Surrey side, one of the trees has been cut completely through, about three and a half or four feet from the ground, with, apparently, a strong knife or a small hatchet, the top having been left, as it was growing, between the supporting stakes. A little further on towards Westminster, another tree also bears marks of injury, an attempt to lop which has since been made by covering the wound over with clay, and keeping it in its place by means of a bandage. A few yards further on another tree appears to have received a knock from some blunt instrument, probably the back of a hatchet. This also has been dressed with clay. This last tree has been damaged higher up

the stem than its injured neighbours, the wound it has received being about four and a half feet from the ground. The Embankment gardens, say the daily papers, are to be ornamented with evergreens on the occasion of the Queen's passing that way to or from St. Paul's Cathedral on the 27th instant, and already some five thousand laurels, hollies, box, firs, &c., bought at different nurseries for that purpose, are being planted in conspicuous positions. How long they will withstand the change from pure air to our smoky atmosphere remains to be seen.—ED.]

THE AMATEURS' REMEMBRANCER.*

Flower Garden and Shrubbery.—Trees and shrubs prune, removing all decayed and unsightly branches, and thinning and regulating where overcrowded. Alterations bring to a close quickly. Flowers like deep and porous borders; but they should not be made too rich, as in that case the plants, especially in rainy seasons, run too much to leaf.

Pots and Frames.—Plants in these examine, freeing them from dead or decaying leaves, stirring the surface mould, and otherwise keeping them clean. *Auriculas*, top-dress with rich soil, and young plants in small pots shift into larger ones, and as the plants start into active growth increase the supply of water; protect from heavy rains, and give air on all favourable occasions. *Calceolaries*, shift, and keep in a genial moist atmosphere. Sow *mignonette* on a slight bottom heat, in rich soil. Re-pot stocks, and encourage them; some ten-week stocks may also be sown. Carnations, clear of dead foliage, and stir the surface soil. *Ranunculus*, sow in pans, and place in a cool close frame.

Indoor Plant Department.—There will be no difficulty now in keeping conservatories and greenhouses gay and attractive, seeing that hyacinths, tulips, and other early flowering plants, are coming so freely into bloom. As the days advance in length and warmth, more encouragement may be given to regular occupants of these structures. Plants for successional blooming should be introduced into the forcing-pit, such as *Lilacs*, *Ghent Azaleas*, hybrid *Rhododendrons*, &c. Room must also be found for Chinese *Azaleas*, *Roses*, and bulbs. *Dipladenias*, *Allamandas*, *Ixoras*, and *Stephanotis*, for stove ornamentation, should also be started if wanted early; and the various kinds of *Achimenes*, *Gesnerias*, *Gloxinias*, and other bulbous stove plants must likewise receive attention. *Tea*, *China*, and *Bourbon* *Roses* may now be increased where the stock of such things is deficient.

Indoor Fruit Department.—Shift some of the best succession *Pine-apples* into their fruiting-pots; keep the root temperature from 80° to 85° and the atmospheric about 65°. Take suckers off old stools with a "heel," and pot at once into seven or nine inch pots. Vines breaking require a moist atmosphere, and those in bloom a rather dry one. A' soon as grapes are set, thinning must commence; and admit carefully air avoiding cold draughts. Peaches and nectarines set, will require thinning, and also syringing morning and evening in favourable weather; disbud and keep them free from insects. Figs like plenty of water and frequent syringings; pinch off the terminal bud at the fifth joint. Cherries keep cool till ripe, and water very moderately; temperature 45°, and admit air freely. Of strawberries keep up successions, and remove such as have fruited. Tomatoes sow in three-inch pots, and push on in heat. For cucumbers, prepare succession beds, and plant those already made, keeping the plants about six inches from the glass. Shift seedlings into three-inch pots when they have made the third leaf; afterwards pinch the leading shoots. Melons sow in small pots and when they make two rough leaves, shift, when they make three or four rough leaves, pinch; night temperature 60° or 65°, day temperature by sunheat, 80°; keep the atmospheric moist. Muskmelon beds, when about 60°, spawn. Radishes sow in gentle heat. Mustard and cress sow successionaly once in ten days. Capsicums and chilles sow in strong heat, and prick off as soon as up, an inch apart. To potatoes under glass, admit air freely; water only the soil, and top-dress with light mould. Of rhubarb bring in successional plants for forcing. *Scallakes*, lift and place in a mild temperature away from light, to blanch. Kidney Beans sow in pots for succession; pinch off the top shoots, and syringe frequently. Asparagus add fresh linings to, maintain a temperature of 60° or 70°, drawing off the sashes in fine days. Celery sow on a slight hot-bed, or in boxes or pans.

Hardy Fruit and Kitchen Garden.—Trenching and manuring finish as early as possible. Prune outdoor vines. Plant and prune bush fruits. Scions for grafting put in by the "heels" till required, and head back stocks to receive them. Orchard trees thin where crowded. Finish training and nailing, especially on south walls; and syringe peach trees afterwards with sulphur and water. Of strawberries, make new plantations if necessary. Of beans sow a general crop, also a second crop of tall and dwarf peas. Of potatoes a full crop may now be planted. Some early turnips sow on a warm border. Of parsley sow some of the best curled, in drills a foot apart. Of cauliflower make a small sowing, prick out those in boxes or pans, and plant out some strong well-hardened plants of autumn sowings. Carrots sow a few *Early Horn* on a warm border. Of cabbage sow an early variety on some warm spot, and transplant autumn sown. Of broccoli sow *Walcheren* on a warm situation. Radishes sow both long and turnip-rooted, protecting should the weather become severe. Garlic plant in drills two inches deep, nine inches from each other in the row, and the rows twelve inches apart.

* Complete monthly calendars, written by some of our ablest gardeners are published in THE GARDEN in the first issue for each month.

NOTES AND QUESTIONS ON PUBLIC GARDENS.

Victoria Park.—We understand that the thirty acres of reserved land have been secured for the public. Mr. Lowe and Mr. Ayrton have agreed with the Board of Works as to terms. This is a satisfactory termination of a gallant fight, which seemed almost hopeless when Mr. Lowe gave the adverse answer to the deputation which waited on him a few weeks since. It was Mr. Reed, M.P., who, on that occasion, if we remember rightly, proposed, as a last resort, to appeal to the Board of Works in the matter, and the result has been success obtained in the eleventh hour.

Public Park for Ashton-under-Lyne.—The Earl of Stamford and Warrington has generously proposed to give a tract of land, lying between the towns of Ashton-under-Lyne and Stalybridge, of the value of upwards of £10,000, for the formation of a public park for the district, on the condition that the inhabitants will subscribe the necessary funds for laying out the park and its approaches. Mr. Darnton, solicitor, and the ex-mayor of Ashton-under-Lyne, has also offered to convey a plot of land, containing about nine and a half acres, and also a large mansion thereon, known as the "Highfield estate" (late belonging to Abel Harrison, Esq.), to form part of such park, for the sum of £2,000. The Highfield estate is subject to a yearly chief rent of £181, payable to Lord Stamford, which his lordship has also generously consented to forego.

The Alexandra Park Company.—The winding-up matter of the Alexandra Park Company was before Mr. Church, the chief clerk at the Rolls' Chambers, this week. The official liquidator said it had been mentioned in the public press that the creditors would be paid in full. Already they had been paid 17s. 4d. in the pound. All that was expected further would be twopence in the pound. The chief clerk said he wished that all public companies that came before him paid 17s. 6d. in the pound. He allowed the matter to be adjourned.

"Pour les Dames."—What must foreigners think of our most modest style, where health is in many unavoidable cases sacrificed for appearance sake? Why are our large parks and promenades so destitute of accommodation for women, and why is the little that exists so carefully hidden from knowledge as well as sight? Why should private individuals be left to provide for so great a public want? Such provision must always be inadequate, more particularly so when payment is demanded for that which vestries ought to supply and care for gratuitously. Retiring places, *pour les dames* should be erected in convenient corners, and one section should be free, whether in park, or street, or railway-station. The sterner sex has less to complain of than a comprehensive system might be instituted that would provide for all requirements, without being indecorously obtrusive.—*Lantern*, in "*Builder*."

COVENT GARDEN MARKET.—February 10th.

Flowers.—These consist of *Hyacinths*, *Tulips*, and *Crocuses*. *Callas*, *Heaths*; common and Chinese *Primulas*; *Cyclamens*; *Azaleas*, both Indian and Ghent; *Camellias*; *Deutzia gracilis*; *Laurustinus*; *Acacias*; *Thysanthus rotundifolius*, one of the most striking of winter-flowering plants; *Dierama spectabile*; *Bovardias*; *Paleromia*; *Cytisus*; the sweet-smelling *Daphne indica*; *Fuchsias*, *Lily of the Valley*; *Violets*; *Mignonne*, *Wallflowers*, *Begonias*, *Christmas Roses*, *Lilacs*, *Tea* and *China Roses*, *Snowdrops*, *Arabis*, *Spiraea japonica*, *Cinerarias*, *Winter Aconites*, *Hepaticas*; and some cut flowers of *Orchids*, such as *Dendrobiums*, *Odontoglossums*, *Zygopetalums*, and *Cypripediums*. Among bemed plants are *Solanums*, *Ardisias*, and *Aucubas*.

Prices of Fruit.—Apples, Dessert, 2s. to 4s. per dozen.—Cobs, per 100lbs, 60s. to 65s.—Filberts, per lb., 8d. to 10d.—Grapes, per lb., 5s. to 10s.—Lemons, per 100, 7s. to 10s.—Oranges, per 100, 6s. to 10s.—Pears, per dozen, 3s. to 8s.—Pine-apples, per lb., 6s. to 10s.—Pomegranates, each, 4d. to 8d.

Prices of Vegetables.—Artichokes, green, each, 6d. to 8d.—Asparagus, per 100, 8s. to 10s.—Beet, per dozen, 1s. to 2s.—Broccoli, purple, per bundle, 10d. to 1s. 3d.—Brussels Sprouts, per half sieve, 2s. to 3s.—Cabbages, per dozen, 10d. to 1s. 3d.—Cucumbers, per 100, 6s. to 12s.—Carrots, per bunch, 5d. to 7d.—Cauliflowers, per dozen, 2s. to 6s.—Celery, per bundle, 1s. to 2s.—Chillies, per 100, 1s. 6d. to 2s.—Cucumbers, each, 1s. to 2s.—French Beans, new, per 100, 3s. to 4s.—Herbs, per bunch, 2d. to 4d.—Horse Radish, per bunch, 3s. to 5s.—Leeks, per bunch, 2d. to 4d.—Lettuces, per score, 1s. 6d. to 2s.—Mushrooms, per portion, 1s. to 2s. 6d.—Onions, per bunch, 4d. to 9d.—Parsley, per bunch, 2d. to 4d.—Radishes, per bunch, 2d.—Rhubarb, per bundle, 1s. 6d. to 2s.—Salsify, per bundle, 9d. to 1s. 3d.—Scorzonera, per bundle, 9d. to 1s. 3d.—Seakale, per punnet, 1s. 6d. to 2s. 6d.—Shallots, per lb., 8d.—Spinach, per bunch, 3s. to 4s.—Tomatoes, per small punnet, 3d. to 6d.—Turnips, per bunch, 3d. to 6d.

Part I. of THE GARDEN, containing 6 Numbers and upwards of 80 Illustrations and Plans, may now be had, price 2s. Part II. is also now ready, price 1s. 5d., and may be had through all booksellers and newsagents, and at the railway stalls.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

GARDEN

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

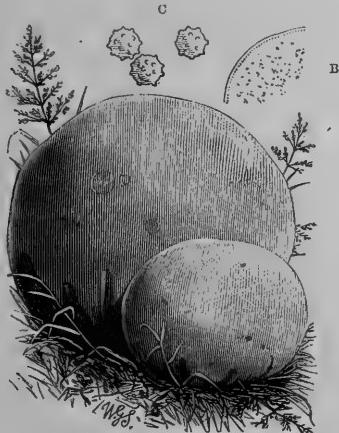

Readers who may find it difficult to procure THE GARDEN regularly through the newsagents, may have the numbers sent direct from the office, at 19s. 6d. per annum; 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsagents, at the railway book-stalls, and from the office.

THE HOUSEHOLD.

THE GIANT PUFF-BALL.

(LYCOPERDON GIGANTEUM.)

THERE is no deceptive puff about the Puff-Ball here figured—in fact, it needs no puffing; for its character, like its unsullied snow-white coat, is purity itself. These delicious puff-balls are nature's real "lumps of delight," and may be purchased everywhere in every field and pasture of autumn, for nothing an ounce. These are the proper "balls" for young and old to study. It is far better to be dancing over

A.—The Giant Puff-Ball. B.—Section of ditto.
C.—Spores enlarged 700 diameters.

the September meadows after such epicurean treasures as Lycoperdon giganteum & Co., than to be capering with the light fantastic toe over Turkey carpets during the small hours of morning. As for other "balls," such, for instance, as those the Prussians and French have familiarised us with in their fields and cities, why, they are too frugal for Fungologists to think over for a moment; better study at once, and for ever, the "terrestrial globes" here illustrated, the pleasures of which are warranted never to cloy.

Dr. Bull states that the Puff-Balls are edible when young; and we consider the Giant Puff-Ball to have a great pre-eminence over all the others. It may be at once known by its great size, commonly measuring a foot in diameter, its snow-white colour, and its texture like the finest white kid leather,

with the skin frequently breaking into minute areas. It grows with great rapidity, and is common in rich pastures, gardens, and orchards, usually irregularly scattered, but occasionally growing in enormous fairy-rings. When the interior of the Puff-Ball is perfectly white and firm, it is fit for the table. We consider the allied species not worth experimenting upon; these may be small, and found growing upon stumps, palish brown in colour, or large, and covered with warts. Our plant is different in all these characters.

Boys take an especial delight in kicking these great puff-balls to pieces. Undoubtedly, they are very alluring, and present just the same temptation to boys as the venerable bald human head does to the irate Irishman, inasmuch as the damage can be so clearly seen after the first hostile blow from the foot or shillalah—both are so easily "caved in."

It generally happens that a single good-sized puff-ball is far too large for a single day's consumption. Should the plant, therefore, be found growing in a garden or any similarly convenient place, the better plan is to cut a few slices off the living plant, and let the bulk remain growing (just as the horse's haunches were treated in the apocryphal traveller's tale); by these means, as Vittadini says, one may have a *frittura* every day in the week.

The best authorities agree in stating that no French omelette is half so good in richness and delicacy of flavour as the Puff-Ball omelette. Dr. Curtis, of South Carolina, calls it the "South Down" of mushrooms, and says, "it has a delicacy of flavour superior to any omelette ever eaten."

Cut slices a quarter of an inch thick, and fry with butter; then spread over them raspberry jam or jelly, or any similar sweet, and serve hot. For fritters, cut slices half-an-inch thick; dip in yolk of egg; sprinkle with pepper, salt, and sweet herbs; fry in fresh butter, and serve hot. The Giant Puff-Ball is one of the lightest, most digestible, and delicious of all fungi.

W. G. SMITH.

THE KITCHEN GARDEN.

KITCHEN GARDEN ROTATION.

With reference to farm crops, it is only in exceptional cases where two white straw crops can be taken profitably in succession; and so injurious has the practice been found to be to the land, that most proprietors covenant that a proper and customary rotation shall be observed in the cultivation of the soil. Hence the origin of the two, three, or four course systems of cultivation, and hence, also, the rotation of crops. Before this system was introduced, land used to lay fallow every three or four years in order that it might be cleared of weeds and properly cultivated; but now, by the alternations of straw and green crops, fallows are rendered altogether unnecessary, except in cases of gross neglect where perennial weeds have been allowed to accumulate in a very undue manner. Now in the management of a garden we have always found it necessary to divide the area, be it large or small, into five equal portions. One is devoted to perennial or permanent crops, such as Asparagus, Seakale, Rhubarb, Horse Radish, and the like, and once properly planted, these, beyond the ordinary rules of manuring and cleaning from weeds, require little attention. Strawberries we suppose to be grown upon the wall tree borders, and fruit trees are cultivated in single lines running parallel with the walks. This leaves the four equal proportions which we have specified open for a specific rotation, which may be carried out in a systematic manner. Now, of these crops we have what may be called deepeners, cultivators, and exhausters. Thus Celery, Cardoons, and early Potatoes in trenches may be called deepeners, inasmuch as they necessitate the shifting of the soil to a considerable depth, both in forming trenches and earthing. Surface crops are called cultivators, because the frequent hoeings necessary for the destruction of weeds exposes a large surface of the soil to the action of the atmosphere; and exhausters are such root crops as Potatoes, Parsnips, Carrots, and the like, which scourge the ground of its manure and make it poor indeed, and consequently it is necessary that such a rotation should be observed that the deepeners follow the exhausting crop. To this end we make the deepeners Celery, &c., our leading crop. Therefore Plot 1 will be

planted with Celery, heavily manured, and also with Potatoes in trenches on hot dung, and this plot will also contain the Cucumber or Vegetable-Marrow ridge. Plot 2 will be planted with Onions, Cabbage, early Cauliflower, and Carrots. Plot 3, summer Spinach, Turnips, and dwarf French Beans, followed by Broccoli and Brussels Sprouts for the winter; and No. 4, the general crop of Potatoes, interlined with Brussels Sprouts and Winter Greens, or manured after the Potatoes are taken up and planted with autumn Coleworts. By this succession there is no vacant ground; each crop falls systematically into its allotted space, the ground by the preceding crop being properly prepared for its reception. Thus after the exhaustion of the soil by the root crops upon Plot 4, Celery and its companion crops step forward from No. 1, and by the deep trenches and heavy manuring restore its lost properties. Onions and Cabbage follow, which delight in deeply cultivated and highly manured soil, and these are followed by crops which rejoice more in surface cultivation. In this manner the round of the cropping may be kept on for a century without the soil being deteriorated, always premising that it receives manure with a liberal hand, and that no opportunity of trenching and ridging the ground as frequently as the absence of the crop renders such treatment practicable is neglected. It will be observed that in this rotation I have not said anything of Peas and other tall-growing leguminous crops. I suppose them to be grown in rows, eight, twelve, or fifteen feet apart, and that the minor vegetables are grown between them; always, of course, taking care that they do not stand upon the same ground two years in succession. Thus, if around the plot you have pyramidal Apple, Pear, or Plum trees, and bush fruit, Gooseberries and Currants, planted alternately, say six feet apart, the Peas this year will come opposite the tall trees, while next year their station will be opposite the bush fruit. By this system of cropping I have always realised the most complete success in the cultivation of vegetables of all kinds. Now, in the cultivation of the permanent crops, if it is customary to take up Asparagus, Seakale, or Rhubarb for forcing, I always contrive to have an improving crop upon the space. Thus, after Asparagus, I would have a ridge of hot dung and garden refuse for the cultivation of early vegetables or Cucumbers or Vegetable Marrows, and that trenched up and well incorporated with the soil would make a fit preparation for Asparagus in the following season, and by the same rule trenches for early crops assisted by hot dung would prepare the Seakale and Rhubarb ground for succeeding crops. Of Strawberries and such light crops as Lettuce and other salads, I say nothing, as I suppose them to be confined to the wall tree borders, and to such aspect as the varying seasons may render necessary.

P. A. W.

HARD GROUND FOR BROCCOLI.

In penning a few notes on this esteemed vegetable, I have little new to offer, but merely purpose to describe a practical method of treatment, which, if carried out, cannot fail to give satisfactory results. Just now (December) we have a good stock of Walcheren broccoli, well covered with fern—the best of all protectors for outside things, to be followed by Snow's Broccoli, also covered up.

For my first crop of Walcheren, I sow the seed about the middle of August, and plant (under hand-lights) in the first week of October all the larger plants, reserving the small ones for three-light boxes, which gives me a succession from the first week in June until the last in July. These are followed by a pinch of seed sown inside in February, which comes into use in August. In March we make a sowing on a south border, and another the first week in May; and by picking out all the best plants first, leaving the smaller fry for the last batch, we are enabled to keep well on until Christmas.

The land cannot be too highly tilled for cauliflowers, trenching and manuring being the order of the day; but for spring broccoli the case is different. We want good stocky plants. They are the following crop after the early potatoes are cleared, and the firmer the land the better. We strike the lines three feet apart, and plant two feet six inches apart in the row, one man making the holes with a crowbar, and another dropping in the plants. The only planting required is to well wash the dry earth into the holes, filling them level with the ground; and they seldom require any more water. We never lift or lay in our broccoli, the plants being sturdy and hardy; but in severe weather we cover with fern, the wind, rain, &c., washing it down to the neck, and thus preserving them.

The following varieties keep us supplied with broccoli nearly the whole year round.—Snow's Winter White; Osborn's, a really good thing; Early Malta; Frogmore Improved, for early spring, say January to April, when we have Elleton's White Protecting, Hibbie's Royal Alfred; and for latest of all, Cattell's Eclipse, the best of all broccolis for late work.

As an illustration of broccoli-growing in firm land, I may mention that when taking charge of these gardens three years back, I found a quarter which had been occupied by strawberries for eight years. The crop of fruit being cleared, I had the plants all chopped up close to the surface, the land, which was as dry as dust, raked over, and the plants planted in the manner above described; and I never saw so fine a piece of broccoli stand before the sun. High manuring and deep digging give foliage three feet long; but this is not wanted. What is required, is to give plenty of room, and grow the plants stiff and firm. I sowed my early broccoli the first week in April, and the late the first day of May.—R. Gilbert, Burghley, in "Florist and Pomologist."

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Thin Seeding.—Crowding is one of the sins of the small gardener. Because he is pinched for space, he must crowd his plants, forgetting that every living thing must have room to grow, and if it has not, attenuation must be the consequence. Of this there can be no doubt, and yet so covetous are many, that a man with a few score plants more than he has room for would rather spoil the lot than give or throw them away. With good and thick sowing is waste, and the neglect of timely thinning must result in the injury of the crop. Where there is time, as is generally the case with amateurs, it is a capital practice to drop the seeds of onions, carrots, and the like at those distances apart which they require for full growth. Three or four seeds in each patch will be quite sufficient, and as the distance admits of thorough cultivation around the plants, superior growth is the consequence. This is something like dibbling the corn crops, a pint or two of seed upon properly prepared ground producing as great a return as when two or more bushels are sown. With scarce or expensive seeds, dibbling is a decided advantage.

Garden Allotment Agreements.—As agent for the Hon. Mark Rolle's South Devon estates, I beg to say, in answer to "Kestrel's" inquiries, that I have let several hundred allotments with the best results, and without the loss of a shilling of rent, on the following terms:—1. All allotments 20 perches in extent. 2. Rent (generally 5s.) payable in February in advance. 3. Ploughing and subletting prohibited. 4. Landlord reserves power to resume possession any February without notice, on paying for crops and unexhausted manure. 5. Landlord pays all rates, taxes, and tithes. The allotment field should be as close as possible to the village, and, if not naturally dry, should be drained; accommodation roads or tracks should intersect the field, so as to give access to all the allotments; numbered boundary stakes should define limits, and, to avoid jealousy, applicants should, in the first instance, draw lots. I believe that allotments are great enemies to publicans, and that if any notorious offence forfeits a man's allotment, the effect is good; but I have very rarely had to resume possession. If "Kestrel" wishes to make money by allotments, he will find that in most villages labourers will give 10s. for 20 perches of fair arable land on the above terms; but, perhaps, like my employer, he is ready to accept 5s., and so show the labouring man that there are advantages in living under the wing of a large landed proprietor. Allotments give an agent some trouble, especially in the out-of-the-way country parishes rather than the rule.—R. H. Lipscombe, East Budleigh, Budleigh Salterton.

Foolish Trenching.—For a good garden, as I have said, a deep rich soil is essential; and to this end trenching is desirable; but trenching will not always secure it, for the palpable reason that subsoil is not soil. I have met with certain awkward confirmatory experiences, where a delicate garden mould of some ten inches in depth, which would have made fair show of the lesser vegetables, has been, by the frenzy of trenching, buried under fourteen inches of villainous gravelly hard-pans, brought up from below, in which all seeds sicken, and all plants turned pale. Whatever be the depth of tillage, it is essential that the surface show a fine tilt of friable, light, uncultivated mould; the young plants need it to gain strength for a foray below. And yet I have seen inordinate sums expended for the sake of burying a few inches of such choice moulds, under a foot-thick coverlid of the dreariest and rawest yellow gravel that ever held its cheerful face to the sun.—*Ik. Morel.*

The Plough in the Market Garden.—Many, without pretensions to that nicely of culture which is supposed to belong to spade husbandry, so overstock their gardens with confused and intercepting lines of fruit shrubbery, and perennial herbs, as to forbid any thorough action of the plough. By the simple device, however, of giving to the garden the shape of a long parallelogram, and arranging its trees and walks in lines parallel with its length, and by establishing easy modes of ingress and egress at either end, the plough will prove a great economist; and, under careful handling, will leave as even a surface, and as fine a tilth as follows the spade. I make this suggestion in the interest of those cultivators who are compelled to measure narrowly the cost of tillage, and who cannot indulge in the amateur weakness of wasted labour.—*My Farm of Edgewood.*

THE ART OF GRAFTING.

(Continued from Page 258.)

GRAFTING UNDER GLASS.

GENERAL DIRECTIONS.—Certain plants require to be propagated under the shelter of a cloche, frame, or greenhouse. Such are evergreen trees and shrubs, tender, rare, or new plants. Evenness of growth and equability of temperature, keeping the subjects from exposure to the air or other adverse influences, very much promote the union of the graft. The stock is a young plant which has been potted, and allowed to grow in the open air for about a season. When it is time to graft it, it is put under cover. There are, however, certain shrubs which may be grafted at the time when the stock is potted; such as the Holly, Rhododendrons, dwarf Biatas, and most shrubs the roots of which readily group themselves into a ball. The best seasons for grafting under glass are from January to March, and from July to September. Beyond the shelter of the greenhouse or other covering, no artificial heat from manure, hot-air or hot-water pipes will be required; and as the stocks are not exposed to the action of the sun, frost or other atmospheric influences, the grafts will not need the protection of grafting-clay or wax. In times of great heat, the glass of the house, frame, or cloche is covered on the outside with a mixture of the colouring-stuff called "English Green" and whiting, or simply with whiting dissolved in water or milk; mats, canvas, or screens made with twigs or small branches of broom, heath or birch may also be used for this purpose. These, if steeped in a solution of sulphate of copper, will not so soon decay.

GRAFTING UNDER THE CLOCHE.—This is the most simple method of grafting under glass, no house, or other shelter than that of the cloche being required. A quadrangular bed of river sand is made sufficiently broad to contain two or three rows of ordinary cloches. In February or March, sometimes in July, the stocks are grafted in pots, and plunged in groups in the sand under the cloches.

The rim of the cloche is sunk in the sand, so as to exclude the air completely from the plants, and they are left so for six weeks. By that time the union of the grafts will be perfected. The cloches are then gradually raised for a week, after which they are removed altogether; but the young plants are kept shaded with canvas or other screens. These are at length removed altogether, before planting the subjects out. The stocks are raised in pots before hand. They may also be sometimes grafted at the same time that they are potted. Evergreens also, which can be taken up with the roots in a ball, are often grafted after they are taken up. They are then planted under cloches, in a compost of good soil, and not potted until two months afterwards, when the cloches are dispensed with. Autumn-grafting under the cloche does not succeed so well, and involves a greater amount of care and attention. During winter, the rows of cloches are covered with dead leaves and straw mats; but it is very rare that severe winters do not leave their marks behind them. The amateur who desires to try grafting under glass, may satisfy himself at trifling expense, by operating in spring with the cloche, and in open ground or nearly so.

GRAFTING IN FRAMES.—The frame consists of a wooden box, set in cement or brickwork about two feet high, and sunk in the ground to one-half its depth. If the height of the stocks requires it, the soil should be excavated from the bottom to a suitable depth, leaving the height of the frame over ground as it was. The frame may be about $4\frac{1}{2}$ feet wide, and should be covered with glazed lights. The interstices between the lights and the frame should be stuffed with moss, in order to exclude the air. At the bottom of the frame is placed a layer of sand,

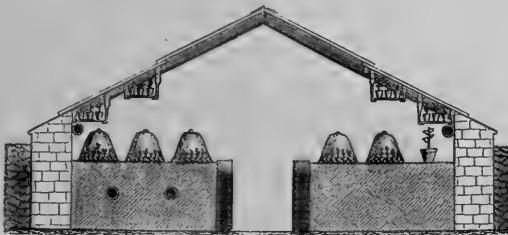

tan, cinders, or even of ordinary soil, in which the subjects are plunged as soon as they are grafted. August is the best time for grafting under glass. The stocks should be grafted in the propagating shed at that time, or from the latter part of July to the commencement of September, and placed immediately in the frames. Spring is also a suitable time for this mode of grafting. As the perfect union of the parts does not take place sooner than five or six weeks after grafting, the air should be thoroughly excluded from the frame during that time. Then the lights should be slightly raised for a few hours every day, when the weather is warm. Should the sun be powerful, tender plants must be shaded with screens or canvas spread over the lights, or by whitewashing the glass. But during the first weeks the frames should be covered with straw-mats.

GRAFTING IN A HOUSE.—The propagating-house here represented is of very simple construction. It is sunk to about from twenty inches to three and a quarter feet under the surface of the ground. The bottom is kept dry by a layer of four to six inches of sand and cinders. The outer walls are sixteen inches thick; the height inside from floor to roof is six and a half feet; and the glazed roof is about four and a half feet wide from the top to the sides. Two raised beds, each three feet wide, are separated by a passage twenty-eight inches wide, and in these beds the stocks are planted as soon as they are grafted. These beds are filled with tan, sand, cinders, or ordinary soil. Instead of one of the beds there might be a shelf, which could be used for holding the potted stocks which are ready for grafting. When the beds are used for raising cuttings, or receiving plants that have been bud-grafted, or for some winter operations, a layer of dung-heaps manure mixed with dead leaves should be applied. The leaves serve to maintain the heat in the manure, an object which also may be effected by a mixture of fragments of cotton waste. Artificial heat is not required in grafting under glass. When the stocks are grafted, which

might be used either inside or outside of the house, they should be arranged on the bed or shell in groups, keeping similar kinds as much together as possible. They are then covered with cloches, which exclude the air, and under which they are kept for six or eight weeks.

Every five or six days the condensed vapour on the inside of the cloche should be wiped off, and the cloche carefully replaced over the plants so that the air may not enter. The omission of this precaution would be more dangerous than neglecting to wipe the condensed vapour from the interior of the cloche. During periods of great heat, the cloches should be covered with leaves of grey paper or the glass of the house whitewashed. Conifers are more hardy than evergreens, and for them this will be superfluous. As soon as the union of the graft is complete, which will be in the space of six or eight weeks, the cloche is removed and the plant left without it for three or four weeks, but still under the shelter of the house; or, should the house be required for any other purpose, the plants may be removed at once to a frame and covered with the lights.

TREATMENT AFTER GRAFTING UNDER GLASS.—After grafting, the subjects are left for six or eight weeks cut off from the external air. As soon as the union of the parts has been established, the plants are still left under glass, but partially exposed to the air in the frame or house, by removing the cloches. If the grafting has taken place in autumn, the plants already grafted in frames are left there, and those which have been grafted in the house are also put under frames, where they will remain during the winter. When spring comes, the lights are raised in the day time; in the month of May the plants are removed into the open air, and should be placed at the north

Propagating-house.

sides of a building or evergreen hedge. If the grafting has been done in spring, the plants which have been grafted under cloches or frames, and which have been already partially exposed to the air, should be put out in the same way in the shade. Plants grafted in a house should be put for a month under a frame, the lights of which should be raised in times of great heat; after this they are put out for a while in a shady place before they are finally committed to the open ground. In nurseries, this shading-quarter is formed by a row of evergreens of compact and well-clipped foliage. The Chinese Arbor vitæ (*Biotia orientalis*) is generally used for this purpose, planted from east to west, so as to afford a full north aspect, and at a distance of two feet from each other. For stocks as tall as five or six feet, a row of trees planted at least six and a half feet from each other will afford an excellent shade. The higher the shading is required to be, the greater should be the distance between the trees which form it, in order to admit a free circulation of air. When the plants are placed in the shade they should be moved into larger pots, and should be plunged in groups in beds at the foot of the shading trees, where they are to remain a year or two in the same pots. When sufficiently grown they are again moved into larger pots. According to their nature they may be subsequently planted permanently in shade, or in the open ground, or in the intermediate position known as the parasol. The parasol is a row of deciduous trees planted similarly to the evergreen shading trees. Every time the plants are moved, whether in pots or not, their roots should be surrounded with a compost approaching in character the soil in which they are to be finally planted. Peat soil mixed with river sand is best for the first stages. Woody plants prefer a substantial kind of nutrient to manures that will ferment and whose action is temporary. Pots with longitudinal grooves in the sides answer well for raising trees and shrubs. After the grafted shrubs have thus gone through the different phases of treatment, which finally conduct them to open-air growth, they thenceforward come under the common practice of the management of hardy plants.—*O. Basset, "l'Art de Greffer."*

(To be continued.)

THE FLOWER GARDEN.

THE WHITE LILY.

I AM happy to be able to endorse, from a practical point of view, all that "Flos" (p. 239) has so charmingly written concerning this lily. It is peerless in purity, beauty, and fragrance, while it lasts. Like a good many old things, it need not be discarded for newer beauties. It is as effective for back rows of ribbons, centres to foliage, and other plants as on the old herbaceous beds or borders. It is, indeed, worthy of a place of honour in every garden; it is readily increased, and easily cultivated; it flowers best, however, if not too frequently disturbed. You have shown what it is in a mass, with an architectural setting; it is well nigh as effective in lines—and though it may seem presumptuous to write it, after Shakespeare's reference to the futility of gilding refined gold, yet have I seen the effect of the lily heightened by being fronted with scarlet and backed with blue *Salvia patens* in the rear. For many years a line of lilies has been queen of a ribbon border here throughout the month of June. For the time they fill all eyes, and, as it were, obscure, by their superior beauty, all else. When the lilies fade and die, a strong row of the dwarf *Dahlia alba multiflora* takes their place, and well occupies the ground the lilies have left vacant. We have other lines, groups, and patches of white lilies in various positions, and everywhere they flourish.

It would be quite possible to work the grand golden, and other lilies into our bedding arrangements in a similar manner, and by such means to add new interest and beauty to our grouped flowers. Besides, in every garden of any extent lilies and other old-fashioned favourites might have separate beds, borders, and gardens wholly, or chiefly, to themselves.

D. T. F.

CHEAP ROSES.

"I AM only a Dog Rose, and as such, cannot expect much attention; nevertheless the stock from which I sprang lay claim to having been the progenitors of the Queen of the Floral World; a

position, however, untenable without the assistance of my humble brotherhood. This I should not object to, could our aid be given without torture in the shape of mutilation. First, our lower extremities are cut off until we have not a toe on which to support ourselves; then our heads are ruthlessly removed; we are set in rows uncomfortably close; and almost as soon as we begin to assert our natural rights, we are subjected to the drudgery of having to support some of our royal relatives. If we have an eye to growth it is ruthlessly put out—in fact we are simply made use of, in the full acception of the term, and have little to thank the world for. True, on one fine June morning, when a number of our family who had taken up their abode in a quiet corner were decked out in their delicate blush robes, I once heard a young lady remark, how beautiful we looked, but this was an exceptional occurence. There are comparatively few nowadays who can appreciate natural beauty. But I am digressing. My business has reference to our royal relatives. Recently another member of our family, who has shared a great deal of the torture inflicted upon ourselves—Miss Manetti is her name—came amongst us, her countenance radiant with joyful intelligence, which was, that an individual who signed himself 'Y.', and who appears to take an interest in our common family, had signified that he had discovered a method by which the royal section of our family could be upheld in their present position of honour; may, could even be made to increase their number and dominion to an unlimited extent without our assistance, thereby sparing us the grievous mutilation already complained of. Imagine our joy at such good news. We were all ready to burst our buds with expectation, which was heightened by the question being publicly asked of 'Y.' what his method was; the querist being 'T. D. F.', who takes an interest in our well-being, and, if report is correct, is remarkable for his kind disposition; though, in truth, I must say that hitherto, in displaying his loyalty to the *Floral Queen*, he has acted towards us just as hard-hearted as the rest of his species. Yet I have no doubt he and others would be only too glad to be able to spare us the bad treatment necessity has hitherto compelled them to inflict. We naturally expected that 'Y.' would have revealed his secret, and so put an end to all our trouble. Imagine our dire disappointment when we learnt that he refused to disclose his secret. There was mingled disgust and resentment in every countenance. I believe the spines on some of the young and vigorous of our community grew at least half an inch longer in no time; and the general expression of all was such, that if 'Y.' had been within hearing, he would never have forgotten it. A general consultation was held as to what punishment he was deserving of, when it was proposed that if it were possible to find him, he should receive a sound castigation with half-a-dozen of the strongest spined young briars, until not a thorn remained upon them. The proposition was carried by acclamation, and all expressed their conviction that 'Y.'s secret would do him no good, as it, or something equal to it, was sure to come out that would be a general relief to us Dog Roses."

Happening to be in an outside corner of the garden, where a number of briar and Manetti stocks are planted, I overheard the foregoing recital, and promised the stocks that if I could in any way assist them, I would do so.

There is a method which I have tried years ago, and by which, with proper attention and well-directed practical skill, ten out of every dozen roses will strike root with a little practice in selecting the cuttings. After blooming, about the end of July, when the wood is about half ripe, select your cuttings, put them in pots, but not too thickly; give them a good watering, and then place the pots as closely as they will stand in cold frames under a north wall; keep the frames shut; in about three weeks the cuttings will have callused; then plunge the pots in a nice bottom heat, and very few will fail to root in a very short time. They can then either be kept in the pots through the winter, or they can at once be placed singly in three-inch pots, and wintered in pots where frost is excluded. As will be seen, the secret in this method is simply callusing the cuttings before they are put in heat to strike. If the cuttings are once placed in heat as soon as taken from the tree, great numbers of them damp off. The number of plants that can be propagated by the above method is only limited by the cuttings available.

Southgate.

T. BAINES.

WILL you kindly inform "Y." (the cheap rose-grower) that I think it is rather too bad, after making people's mouths water by telling them that "rose cuttings" could be "struck like willows," to withhold his secret.—G. S., Cheltenham.—[We feel ashamed of anybody who wishes to hide any new pebble he has found on the shores of "thy great ocean, Truth." We believed in the existence of such poor beguiled creatures, but scarcely thought they would have the hardihood to announce in one note, "We have it," and in the next, "You shan't see it."]

TOBACCO IN THE FLOWER GARDEN.

THIS is truly a fine foliated plant, of goodly stature and right royal mien, and one well suited for our modern style of gardening. There are several varieties of it, varying chiefly one from another in the sturdiness and height of their stems, and size of leaf and flower. But these variations are also largely dependent on cultivation. The deeper and richer the ground, and more sheltered the position, the larger tobacco plants become in all their parts.

The variety represented is probably the very best in habit and general characteristics for what is termed sub-tropical gardening. It is simply a variety of the common Virginian tobacco (*Nicotiana virginica*); the leaves are of medium size, and the habit branching. For a large sort of tobacco-to contrast well with this, *Wigandioides* is a grand plant. Pushing up a huge stem to a height of from six to nine feet, with numerous broad, woolly leaves, it forms a grand background to Cannas, Castor-oil plants, or *Wigandias*. The flowers are also larger and much more conspicuous than in other kinds, and they stand well up on the crown of the stems. Then these, scarcely any plants are more useful in leaf gardening, though, indeed, it is hardly fair to call these tobaccos foliago plants only. The long tubular blossoms are highly novel in appearance, resembling somewhat at a distance long, narrow foxglove flowers on slender foot-stalks.

Scarcely any plants equal the tobaccos in rapidity of growth. They form noble groups of themselves, and they mix kindly and congenitally with most other fine-foliated plants. They are great eaters; indeed, it is almost impossible to overdo them with food, solid or liquid. If every smoker had to grow his own tobacco with his house-slops, the sewage nuisance would be much abated, if not wholly cured. The stronger the drink, and the more of it, the faster tobaccos grow. Try them, if possible, in a deep soil, rich in vegetable and animal remains, near the margin of a lake or stream, and note how they grow. They form capital backs to masses of reeds, Pampas grass, bamboos, rushes, or semi-aquatic vegetation of various other descriptions.

They are tender, but not so much so as *Solanums* or Castor-oil plants. Sow them in February in heat, prick off as soon as the plants appear, and pot and grow them in a genial heat of, say, 60°. This will enable you to turn out, from six or eight inch pots, fine plants about the end of May. They will start off at once, and will not cease growing until frost comes. I seldom, however, leave them to become food for frost. Towards the end of October gather the leaves, pile, dry, and press them. Then dry afresh, and put them aside for dealing death to the aphides. Pull up the stalks, hang them up in bundles to dry in any out-of-the-way place under cover, and use them also, chopped up, for fumigating the houses. Thus it will be seen that tobaccos are useful as well as ornamental.

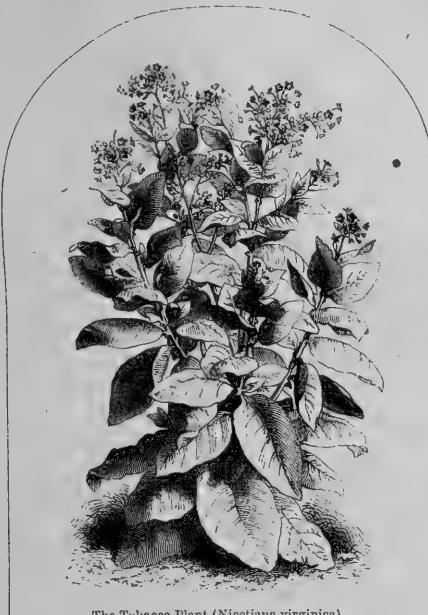

D. T. F.

PEGGED-DOWN ROSES.

BY C. J. PERRY, THE CEDARS, CASTLE BROMWICH.

THERE is, unquestionably, no mode of growing roses so effective as that of pegging them down. Many of our best rosarians, both amateur and professional, have expressed astonishment at the beauty and luxuriance of my beds grown on this plan, and have confessed that they had no idea such effects could be produced in that way even with the Queen of Flowers. It should also be borne in mind that rose beds which once formed and properly attended to are everlasting. There is no dying away every few years, as with roses on the briar or Manetti; and no permanent damage results from frost. Those who grow for purposes of exhibition should never be without such beds; they prolong the "showing" season, and often furnish blooms so grand as to delight even the most enthusiastic exhibitor. I do not say that we should depend entirely on these beds for show flowers, as by so doing we would be debarred from showing new roses; as at least three years must elapse before the plants could produce fine blooms. Still, exhibitors will find them at all times handy auxiliaries. The first-prizes gained by me during the past year at the Crystal Palace, Leeds, York, Wolverhampton, Taunton, and Castle Bromwich, were won mainly by means of blooms cut from my rose beds grown on their own roots.

I am now daily engaged, whenever the weather is favourable, in pruning and thinning out the rods, which this season are the finest I have ever had, many of them being eight or nine feet long, and not in the least damaged by the winter. I therefore expect next summer to have the finest display of flowers I have yet had. Any time between October and March answers for forming beds for pegging down; the ground should be deeply dug, well dressed with farm manure, and drained, if necessary. The plants should be obtained as strong as possible, and must be on their own roots, and, if possible, struck out of doors. They should be planted three feet from each other, and should be cut down to three eyes early in April or in the last week in March. Some

The Tobacco Plant (*Nicotiana virginica*).

blooms will be produced the first season. In February the next year, one of the strongest shoots from each plant may be pegged down, and all the weaker shoots should be cut close to the ground. This season some fine rods will be produced, and the beds will begin to be effective. A good dressing of rotten manure should be given in November, and again in previous to the pegging down in February. A quantity of stout pegs should be chopped from old pea sticks during the winter, so as to be in readiness for use during dry days in this month, when the pegging should commence. All the shoots should be cut away from every plant, with the exception of three or four of the stoutest, which should be shortened about a third of their length and then carefully bent down so that the points may touch the ground or nearly so. Care must be taken in bending the shoots or they will split off at the base, and in inserting the pegs so that they may not fly out of

the ground. Every winter a dressing of manure should be given, and all the wood that has been pegged down cut away, and the strongest of the young shoots only pegged down as before. Many of the pegs can be used a second year; they should, therefore, not be thrown away, but put in a dry place until required.

I must again impress upon growers the necessity of planting only such roses as are on their own roots; all others will be a source of continual annoyance, for no matter how well the stocks may be prepared, the bending down of the shoots will cause suckers to spring up, which cannot be eradicated, and will much interfere with the growth of the plants. A friend of mine, anxious to possess a bed of pegged roses, last year ordered from a nurseryman a quantity of dwarf roses for the purpose. He could not supply them on their own roots, so sent them on the Manetti. One day last May, my friend called on me to say how beautiful her rose bed looked, and wished me to see it when I came that way. Accordingly, about the first week in June, I had a look at this bed, and, to my astonishment and my friend's annoyance, I at once saw that the winter had killed the greater portion of the roses, and that each root had thrown up a quantity of vigorous Manetti shoots, which certainly made the bed look green and luxuriant, but not one shoot in twenty was what it ought to be.

Most of the vigorous growing kinds of roses will answer pegged down, except teas and noisettes, which should never be used in that way.

The following sorts I have thoroughly proved to be good bedders, and can safely recommend them for that purpose:—

Alfred Colombe	Dupuy-Jamais	Madame Clemence Joignaux
Antoine Duchere	Général Jacqueminot	Madame de Cambacérès
Baronne de Wassenach (moss)	Gloire de Vitry	Madame Rivers
Baronne Gonella	Horace Vernet	Madame Victoire Verrier
Charles-Bernardin	Jeanne d'Arc	Monsieur Noisette
Caroline de Sensales	Jean Hippolyte	Prince Camille de Rohan
Charles Lefèbvre	Jules Margotin	Sénateur Vasse
Charles Rouillard	La Duchesse de Morry	Souvenir de Charles Mon-
Comtesse de Chabirillant	La Fontaine	taut
Dr. Andy	La Ville de St. Denis	Souvenir de Charles Mon-
Duo de Rohan	Lord Clyde	taut
Duchesse de Caylus	Louise Petyronny	Thorin
Duke of Edinburgh	Madame Charles Verdier	Vicomte Vigier
Duke of Wellington	Madame Charles Wood	Victor Verrier
		William Griffiths
		Xavier Olivo.

CLIMBING DEVONIENSIS ROSE.

I AM glad to find Mr. Reynolds Hole standing up in defence of this rose. Most of those who possess it speak of its superior hardiness, compared with that of the old variety. Its thorny habit indicates a hardy constitution, and it is rightly considered to be nearly as hardy as Gloire de Dijon. I have known it to stand 16° or 18° of frost, wholly unprotected, on garden arches, away from any house or wall. The flowers of Climbing Devonensis are identical with those of its parent in size, shape, colour, and perfume, and under proper management, its powers, both of growth and blossoming, are wonderful; one plant of it, which was put in four years ago, almost covers the south front of a villa here. Throughout April and May during the last two years this tree has been literally a rose show in itself. Five hundred of its lovely flowers were counted on it at one time, more than a hundred of them measuring five inches in diameter, and some even more.

Climbing Devonensis requires a dry, well-drained soil to assist it in ripening its luxuriant wood. The early, strong, sappy wood should be pinched or stopped when about a foot in length, in order to cause it to break into several shoots, which ripen better than the single rods would do if left unstopped, and which almost invariably flower at each point the first season. For spring flowering the following year, these shoots should be trained laterally and downwards, and little or no pruning is needed beyond thinning out portions of the old scrubby wood in February. Thus treated, Climbing Devonensis is the best white climbing rose in cultivation.

With respect to the old Devonensis, our gifted and well-beloved rosarian, Mr. Hole, has allowed a highly treasonable thought to escape him when he says, "I do not believe that Devonensis was of Anglican origin." "Devoniensis," says the late Mr. E. W. Foster, "was raised by my brother, the late Mr. George Foster, of Outland, near Devonport, a genuine lover of horticulture, and a true florist."* Mr. Geo.

Foster's opinion was that it was produced from the Yellow China, fertilised by the Yellow Noisette Smithii, which was growing alongside of it, as he was constantly in the habit of fertilising his roses. One of some seeds saved at the same time produced a rose much like the Yellow Noisette, but greatly inferior to Devonensis. The latter flowered the first year from the seed-bed, but was small and weak; and the second year, on being budded on a strong stock, it grew so as to be a very fine flower. In the following year, Mr. Pince, of Exeter, offered twenty guineas for it, and it then passed into the hands of Messrs. Lucombe & Pince. It is perfectly hardy, but requires a rich, strong soil. At a flower show at Liskeard last summer, I had the pleasure of meeting a nephew of Mr. Foster, who is a clergyman in Cornwall. We had some conversation respecting Devonensis and its raiser, his uncle. That uncle has passed away, also Mr. E. W. Foster, and, still more recently, Mr. Pince, who had the honour of bringing this grand rose before the public. But I am glad to have been afforded the opportunity of thus reviving the facts of its English origin. It has achieved many a triumph in its onward course. I remember exhibiting at one of the old Chiswick fêtes, nearly thirty years ago, four hundred specimen blooms of it; and shall not readily forget the late Dr. Lindley's appreciation of their fragrance and beauty.

Heartily do I unite with Mr. Fish in his warm praise of Devonensis. It is not only the pride of Devonshire, but of the world, and worthy to be the emblem rose of England's royalty.—H. CURTIS, *Devon Rosey, Torquay.*

ROSE DEVONIENSIS was raised by Captain Foster, a gentleman living at Stoke, near Plymouth, in Devonshire, about thirty years since, the parents being Smith's Yellow Noisette and the Yellow China. After the second time of flowering, the late Mr. Pince bought it, and I believe I am right in saying the sum he paid for it was £40. It was sent out by that gentleman at 21s. per plant. I have not the least doubt that the climbing Devonensis Rose has originated in more than one place.—T. BROWN, *Tooting.*

SOUVENIR DE LA MALMAISON AND CLIMBING DEVONIENSIS ROSES.

A THOUSAND thanks to the Rev. Mr. Reynolds Hole for his courteous and satisfactory answer to my queries respecting these roses. I shall try *Souvenir de la Malmaison* again on its own roots. I do not quite despair of it now, because I remember having a few passable flowers of it late in the autumn. Can it be that the sun is too much for it early in the season? I shall also give the Climbing Devonensis the shelter of glass, though I do not expect ever to love the daughter as I do the mother. Bath is not Bury, but a correspondent writing from that favoured district as to climate, after praising the other good qualities of Climbing Devonensis, says: "It is very hardy, having withstood the severe winter of 1860-61. It grows in almost any soil or situation, even in thickly-built parts of Bath, amidst smoke and dust, where it thrives and blooms in great perfection. So highly esteemed is this variety that there is scarcely a villa residence in this neighbourhood (Bath) where one does not find this rose, and no amateur considers his collection perfect without it. Its blooms are of large size, some of them measuring six inches in diameter, and the shape is most perfect. This is, in fact, one of the best light-coloured exhibition roses in cultivation." There, have I not made the *amende honorable* to the daughter, for the sake, however, of the mother, and the marvellous faith I have in Mr. Hole's judgment? I confess I have never seen it anything like what our Bath correspondent has described it, though I hope to do so some day in that genial home of the Queen of Flowers—Caunton.

D. T. FISH.

A GARLAND OF SPRING FLOWERS.

If I could be well assured that in the procession of the seasons, hoary Winter would not again interpose his unwelcome visage; that February, satisfied with the state of the dykes, would think her mission performed, and give us bright and cheering days to compensate us for pluvious skies and stormy winds; and that blustering March would do his spiritizing gently, I should hail with a perfect pleasure, unalloyed by any taint of fear or uncertainty, the bright and fragrant flowers which the soft and steaming weather has tempted to burst into bloom,

* See Letter of Mr. Foster in "Beauties of the Rose," 1850.

even before the shadow of winter has left us—even so early as the first week in February. It is, perhaps, as unwise to anticipate sorrow as it would be to refuse to be charmed, or to accept the gracious gifts which are proffered to us by our precocious flowers of spring. Let us, then, "take the good the gods provide us" joyfully and thankfully, and weave a garland of these the first gifts of the year.

We will take our first bunch of bloom from *Jasminum nudiflorum*, which has this year produced a profusion of its bright yellow blossom, which, though otherwise charming, yet lacks the merit of fragrance; and so we will associate it with the winter Honeysuckle, so unobtrusively delightful, and which combines the odour of orange blossom with that of its own species, *Lonicera fragrantissima*, which should be in every garden. With this we may place the highly perfumed Chimonanthus fragrans, and the aromatic and brilliant flowers of *Rhododendron dauricum atrovirens*, and its fair cousin, *R. pectoc superbum*; and with these we will associate the lowly *Polygalia Chamæbuxus* and *Erica herbacea*; and now, stooping to the very ground, we may gather the winter Heliotrope, *Tussilago fragrans*, the Christmas roses, *Helleborus niger* and *purpurascens*. Handfuls of Russian and Czar Violets are afforded by the plants transferred from their summer nurseries in November and planted on half sheltered banks. At the foot of the great forest trees, and partly protected by their fallen leaves, we find the golden clusters of the winter Aconite; and, not far off, the pensive and chaste Snowdrop. A few Primroses have coyly appeared, and, more bold, the double Daisies present their bright pink-cushioned heads of bloom. The white Arabis is slowly expanding its blooms, and with the lilac Aubretia will add variety to our garland. The hardy and handsome Cliveden Blue Pansy has not ceased to present its blossoms during the winter, and gives the tint of blue we have so long missed in the sky. The dwarf yellow Wallflower has anticipated the sunshine of spring, and enables us to add its rich orange-coloured blooms to our wreath. A few sprigs of *Lamium maculatum* and the small Periwinkle, both gemmed with blossoms, will give graceful variety to this collection, culled in a short morning's walk amongst the spring flowers; and to the above we have just added Anemone blanda and *Scilla sibirica*.

Those of your readers who cannot indulge in the luxury of conservatories, may thus, by establishing a collection of hardy and early blooming spring flowers, enjoy the delight of gathering daily bouquets, even in February, fresh and sweet, and charming from the bosom of mother earth.

WILLIAM INGRAM, *Belvoir*.

[These remarks were accompanied by a box containing specimens of all the lovely spring, say winter, flowers named above, in fine flowering condition—a greater variety than could be culled at the same date in most greenhouses. Really we too hard upon our "dreary climate," and too neglectful of capacities.]

WILD FLOWERS FOR GARDENS.

THERE is an indescribable beauty in the woods and wilds which you wish to transplant into our gardens, and the materials are unlimited and cheap. I have myself had a beautiful bit of bog garden, wherein I succeeded in growing everything I planted; and I have just finished another bog garden ready for planting. What a grand plant *Parnassia palustris* is for a bog! as are also the double blossomed *Caltha palustris*, *Campanula heteroclita*, *Anagallis tenella*, *Epipactis palustris*, *Orchis maculata*, and others. I grow most things in fibry, sandy peat; and right sure am I that a good bog garden is extremely interesting. *Osmunda regalis*, *Lastrea Orectopteris*, and *L. Thelypteris* do admirably; and what a charming plant is *Saxifraga Cymbalaria* all the year round, either for the greenhouse or out of doors! *Sibthorpia europaea* is a gem for running over moist sand-stones or hanging over moist rocks. The greatest difficulty I meet with is finding working men who will take notice of these plants. They seem to think them too common; yet, who in his rambling over moor and upland has not been entranced with the gems springing up by mossy ripples in sheltered corners? I have often sketched little bits of Nature's gardening in Derbyshire and Yorkshire, and longed for the means to come home and imitate them; and I am certain that many of those charming nooks and corners, that give the true lover of Nature such indescribable pleasure, from the stately foxglove to the tiny moss that gladdens

the sight during the winter months, can be imitated. People seem to know little nowadays of decoration, beyond the few gaudy plants that fashion has employed for these last thirty years. All credit is therefore due to some of our nurserymen for keeping alive many gems, in the way of alpine plants, which otherwise must have been lost. In my plant-collecting rambles, I have picked up the following variegated forms:—

<i>Lamium maculatum</i>	<i>Phleum pratense</i> , var. aureum	Six vars. of <i>Arum maculatum</i> variegatum.
<i>L. album plenum</i>	<i>Melica uniflora</i> alba	A new variety of Lily of the Valley
<i>Thlaspi citriodorus</i>	<i>M. ", aurea</i>	<i>Sedum acre elegans</i>
<i>"</i> variegatum	<i>Lolium perenne</i> , var. <i>" annua</i> , var.	<i>Rumex obtusifolius variegatus</i>
<i>Malva sylvestris crispa</i>	<i>Geum urbanum</i> , var.	And, best of all, <i>Rumex crispus aureus</i> reticulatus; this is a gem.
<i>M. ", variegata</i>	<i>Matricaria</i> , var.	Also many others
<i>Stellaria auren</i>	<i>Spiraea Ulmaria</i> , var.	W.M. ELLIOTT.
<i>Geranium molle arvense</i>	<i>Orchis muscata alba</i> ,	
<i>Holcus lanatus</i> , var.	very fine	
<i>Alpeocurus pratensis</i> , var.		

Beechmont, Sydenham.

BLUE-FLOWERED HYDRANGEAS.

DURING the summer of 1869, I saw in Ireland, in three several localities, very fine examples of blue-flowered Hydrangeas. The first was in the neighbourhood of Lismore, at a small wayside place not far from Lismore Castle, and almost by the side of the River Blackwater. I was told of these blue Hydrangeas at Fermoy, and went to see them. The plants were of immense size, and had been planted over forty years, and the flowers were richly tinted with ultramarine blue. They opened pink, but soon became blue, and as they decayed assumed the pink tint again. These blue Hydrangeas were the talk of the districts, and many persons had obtained cuttings, struck them, and had grown them on as pot plants, only to find them produce pink flowers. When turned out into the open ground, blue flowers would invariably appear. There seemed to be a great deal of oxide of iron in the soil; and to the presence of this, the blue tint, was no doubt traceable. At Castle Martyr, the seat of the Earl of Shannon, near Cork, and again at Muckross, the Hon. Captain Herbert's residence at Killarney, nice young bushes of Hydrangeas, growing in the open ground, were literally covered with huge trusses of blue flowers, the effect of which was quite startling. I am sure I shall never forget them.

R. DEAN, Ealing, W.

LICHEN AND MOSSES.

WE have found beauty in the tree yielding fruit, and in the herb yielding seed. How of the herb yielding no seed, the fruitless, flowerless lichen of the rock? Lichen and mosses (though these last in their luxuriance are deep and rich as herbage, yet both for the most part humblest of the green things that live)—how of these? Meek creatures! the first mercy of the earth, veiling with hushed softness its dintless rocks; creatures ill of pity, covering with strange and tender honour the scarred disgrace of ruin—laying quiet finger on the trembling stones, to teach them rest. No words that I know of will say what these mosses are. None are delicate enough, none perfect enough, none rich enough. How is one to tell of the rounded bosses of furled and beaming green—the starred divisions of rubied bloom, fine filmed, as if the Rock Spirits could spin porphyry as we do glass—the traceries of intricate silver, and fringes of amber, lustrous, arborescent, burnished through every fibre into fitful brightness and glossy traverses of silken change, yet all subdued and pensive, and framed for simplest, sweetest offices of grace? They will not be gathered, like the flowers, for chapter or love token; but of these the wild bird will make its nest and the wearied child his pillow.

And, as the earth's first mercy, so they are its last gift to us. When all other service is rain, from plant and tree, the soft mosses and grey lichen take up their watch by the headstone. The woods, the blossoms, the gift-bearing grasses, have done their parts for a time, but these do service for ever. Trees for the builder's yard, flowers for the bride's chamber, corn for the granary, moss for the grave.

Yet as in one sense the humblest, in another they are the most honored of the earth-children. Unfading as motionless, the worm frets them not, and the autumn wastes not. Strong in lowliness, they neither blanch in heat nor pine in frost. To them, slow-fingered, constant-hearted, is intrusted the weaving of the dark, eternal tapestries of the hills; to them, slow-pencilled, iris-dyed, the tender framing of their endless imagery. Sharing the stillness of the unimpassioned rock, they share also its endurance; and while the winds of departing spring scatter the white hawthorn blossom like drifts snow, and summer dims on the parched meadow the drooping of its cowslip-gold—far above, among the mountains, the silver lichen-spots rest, star-like, on the stone; and the gathering orange-stain upon the edge of yonder western peak reflects the sunsets of a thousand years.—John Ruskin

RHUBARBS AS ORNAMENTAL PLANTS.

In this genus, the grand typical plant, at least for the garden, is still *in nubibus*. Yes; it is still among the clouds that cluster round the lofty peaks of the Himalayas; and, by way of showing that such does really exist, and that, too, under the very appropriate name of *Rheum nobile*, permit me to quote the following description of it in Dr. Hooker's own words. He says, in his "Himalayan Journal":—"On the black rocks the gigantic Rhubarb forms pyramidal towers, a yard or more high, of inflated reflexed bracts that conceal the flowers, overlapping one another like tiles to protect them from the wind and rain. A whorl of broad green leaves, edged with red, spreads on the ground at the base of the plant, contrasting in colour with the transparent bracts which are yellow margined with pink. This is the handsomest herbaceous plant in Sikkim."

These remarks will suggest to all the query, Why has it not yet been introduced? Seeds were indeed sent home by Dr. Hooker; but none of them vegetated, owing to a considerable delay which took place in their despatch homeward, and also to their being sent *vid* the Cape, thus receiving a double dose of the tropics, which is most detrimental to all albuminous seeds. I hope, however, with the now improved and rapid mode of transit, we shall be able to succeed in introducing this and many other plants that are to be met with on the Himalayas, such as the glorious species of *Mecopasis*, its close ally *Cathartia*, and others.

Rheum Emodi (*syn. australe*), the subject of the accompanying engraving, is a Nepal plant, which, besides yielding the valuable drug in its most concentrated form, is so remarkably distinct in general appearance from other forms of Rhubarb with which we are familiar, that it deserves more than a passing notice. When growing vigorously it produces enormous leaves, measuring between seven and eight feet in circumference, with a perfectly plane margin, and a corrugated surface; the colour being of an unusual tint of green. Both upper and under surfaces, as well as the footstalk, are covered with projecting papillæ of a rigid character, that render the whole plant rough to the touch. The flowers are of a deep chocolate colour, and arranged, unlike those of all its congeners, in the form of a spike, with a few secondary branches given off here and there along its extent. I am inclined to think that the species known by the name "spiciforme," said to be a Himalayan plant, will prove nothing more than this plant under another name. This is a noble plant worthy of a place in every pleasure-ground, either isolated on the turf or in groups of plants of a similar character.

Rheum palmatum, a native of Chinese Tartary and the north of Persia, gets its appropriate title from the palmately-cut character of its leaves. As it is usually seen, it is small in stature; but I have a notion that if fair justice were done to it as an ornamental plant, it would receive more general culture. With that object in view, I purpose giving it a trial, having got a plant established in a favourable position.

Could we but dissociate our minds from the culinary

character of Rhubarb, and prize it purely on its ornamental merits, the verdict would unquestionably be in favour of its nobility as an instance of fine vegetable development. The large masses of foliage, beautifully crimped, and undulate as regards the margin, with their dark-green glossy surface, show the effects of light and shadow in a wonderful manner; nor is the intense crimson-tint of the seeds, shaded off to yellow, to be despised as objects of beauty.

Botanic Gardens, Hull.

PUBLIC GARDENS AND WAR.

ONLY a week ago, in writing about the aspect of Paris on the fête of the Jour de l'An, we were speaking of the rapid recovery made by the French capital since its investment, and of the extraordinary faculty of recuperation which belongs to the character of the people. There are places around the gay metropolis, however, where the sorrowful memorials of the desperate calamity which has befallen France will not soon be obliterated.

It may be easy to patch up the shot-holes in a wall, and ingenious workmen even resorted to the device of hiding the ravages made by cannon-balls by means of strong paper covered with plaster of Paris, or a coat of Roman cement; but where you have a bare, melancholy waste of country, with the earth, that once formed grassy slopes or trim shrubberies, all heaped in tumuli and dotted with objects that look like graves marked by rude monuments; where the great trees, that once whispered pleasantly to holiday-makers who sought their shade, are cut down, their blackened, rotting stumps only remaining; where the ornamental lake oozes sluggishly in the thick weedy grass till it becomes a mere pond full of that renewal of life which we call decay—no temporary expedients suffice to conceal such ravages, and the whole place is one sad monument of defeat and melancholy remembrance. In a word, it would be possible to rebuild all the palaces in the world, but nobody can make a great tree grow again. One is impressed with the reflection on taking a step towards the spot where *It* grand old oaks with mighty trunks and spreading branches—themselves remains of *evil days of 1815*—have disappeared, and the destruction of the charming suburban retreat has been completed

Nepal Rhubarb (*Rheum Emodi*).

by the invasion of 1870. This portion of the Park of Princes was the most charming and picturesque spot of the whole wood, full of verdure and brightness. In other places a good deal of French decorative or operatic picturesqueness has been added to it; and, though nature can often even compensate for this sort of interference, we want to escape from it at intervals and seek some remoter shade, some lodge in a wilderness more or less vast. This was to be found in the beautiful coppice near the pool of Anteuil, now, alas, a wilderness. The fresh oasis, far from the dust and turmoil of Paris, is but a dismal swamp. A few surviving trees appear on the horizon, like the last survivors of a brigand cut down on the field of battle. No fair Amazons carry gaily among the open space; no promenaders appear on what once were pleasant walks. When we were last there, one solitary little woman in a white bonnet, represented the throng that once resorted to the pleasant spot, and she seemed to be looking into the gloomy pond, as though she could see reflected there the picture of the melancholy events that had transformed the spot to its present dreary condition.—*Illustrated Times*.

ASPECTS OF VEGETATION.

RIVER SCENE IN GUIANA.

HEAT without water is a destroyer. Heat and abundant moisture are the magicians that populate the earth with stately and beautiful life. On the banks of such rivers as this they hold court. Giant grass and stately palm, and torturing liane and sturdy fig, and broad-leaved Arum and lady-like tree ferns, swarm on the brink of the noble river as if to cool their thirst. The slim branches and light foliage of the willows that follow the fresh waters through almost every vale and by every river over the vast areas of northern Europe, America, and Asia, are seen no more. In their stead are stately trees of the loveliest tropical forms, and the very water weeds are giants. In the foreground of our picture is a fleet of vegetable boats—more carefully built than ever was clipper on Clyde, or Hudson, or Thames. In our northern willow land we have our tiny water

In the noble Victoria, which, under the kind protection of some of our gardeners, has grown and bloomed so fairly in our hothouses, and even in the open air in heated water, we see the Water Lily of these hot and fertile regions. One of the water birds, so abundant in all waters of the American continent, rests on a leaf; but that gives no idea of the supporting power of each fully-grown leaf, which bears a heavy boy without sinking.

W. R.

THE SIX OF SPADES.

CHAPTER III.

SITTING next to Mr. Chiswick, whose dark-brown locks contrast with Mr. Oldacre's silvery hair, like *Perilla nankinensis* with *Cineraria maritima*, my gardener puffs his pipe. Silent and thoughtful, as one who is wise at whist, he knows every trick in spades, and holds winning cards in his hand. We

Aspects of Vegetation.—River Scene in Guiana.

weeds—also with their fleets of little boats—like the 'frog bit', the *Villarsia*, and the water lily, with its sturdy flotillas. But here we have a plant which is not putting forth all its strength even when its leaves are as large as a drawing-room table.* It seems a relic of some old time, when the spirit of vegetation arose upon the waste of waters and appointed this to cover them with verdure while the trees were in their infancy. It is Nature's own aquarium—vast, varied, inexhaustible. The same clear moon and the glory of the heavens that we sometimes see in the murky cities of men (glorious sights, of which we have not yet succeeded in depriving ourselves!), throw their divine radiance over the view, and help to make one wish that so long as men and gardens remain upon this tiny globe of ours such scenes may never perish, but remain to teach us noble lessons. How refreshing is the abounding sense of the majesty and inexhaustible riches and mystery of the vegetable kingdom that such scenes as this puts before us!

* Leaves of the Victoria in this country have measured eight feet across.

have scored the honours, have we not, old friend, in many a floricultural rubber, and proved our capabilities (dare I say our silver cup-abilities?) on many a board of green cloth. Trained in no ducal gardens, taught in no colleges of science, you have learned your lesson, slowly but surely, from the greatest teacher of your art, Experience, bringing to her school that love which she delights to instruct, and which alone can master her laborious tasks. There was never, assuredly, a good gardener yet, who was not first of all a gardener at heart.

My earliest associations with horticulture, recalled as I look upon that old familiar face, were not of a jubilant kind. I have to confess that, at the premature age of five, I gave lamentable proof of my descent from Eve by strong yearnings after forbidden fruit; and that, at six, I was an experienced felon—not, not a felon, for his crimes meet with capital punishment, and mine were avenged elsewhere—but, at all events, an artful thief. Neither so expert nor so shrewd, however, as to escape discovery and a just disgrace. My chief strategy,

when, a tiny brigand, I prowled the earth for prey, was to enter the kitchen gardens as unconcernedly as possible, and then to call loudly, "Dardner! Dardner!" If he responded, I would favour him with one of those spirited comments upon the weather in which we English are so happy, even from childhood, or would make inquiries of a most affectionate (and affected) order as to the condition of his bodily health; and it was, "How do, Dardner? Fine day, Dardner! Dus morning, Dardner dear!" But if there was no respondent in the case, I, the appellant, immediately resolved myself into a Fruit Committee (all articles to be tested by flavour), and proceeded zealously to business.

One dismal day, no reply having been made to my accosts, I had reached the Gooseberries, and had taken up my position as a Squatter in (the vicinity of) the Bush, when I suddenly heard with horrible amazement a rustling sound among the Scarlet Runners, and like a tiger from the jungle, sprang the dreadful Dardner on his prey!

How vividly I recall that awful capture!—the tedious procession to the house, which I did my best to enliven with brisk but ineffectual kicks; the astonished horror of the under-nurse, who immediately foretold my speedy translation to a penal settlement, and could not have expressed herself more severely if I had shot the bishop of the diocese; the trial by Fury, for such the head-nurse seemed to me in her wrath; the solemn sentence, "Put him to bed!" Undressed accordingly (I flatter myself that the operation was attended with some difficulty; there were buttons on the floor, I remember; and the Judge's cap was considerably rumpled), imprisoned, "cribbed, confined," I dreamed a memorable dream. I was in a garden, and a sweet little fairy invited me to climb the magic Beanstalk. Glorious music from the silver horns of Elfland sounded softly around us as we reached the summit and as we wandered among the most beautiful flowers and the most delicious fruits. No Dardners marred the prospect; and the fairy pressed me to refresh myself, with an earnestness which I was unwilling to offend. I was regretting, over my fourteenth Peach, the lamentable escape of juice, which is so inevitably connected with the outdoor fruition of this fruit, and was meditating a transfer of my attentions in the direction of some white Nectarines, when all at once the sunlight faded, and the music was drowned by a thunderous bellowing which shook the "Royal Georges" from their trees. A giant's hand was laid upon my throat; and I awoke to see Nurse at my crib-side, standing before me, as Queen Eleanor before Fair Rosamond, with a cup in one hand (rhubarb and magnesia), and a dagger in the other, to wit, a dry old finger-biscuit, which I was graciously privileged "to take after."

You feel for me, reader;—don't you? I make no attempt, you will observe, to disparage the seasonable use of physic; I know that Nemesis is the sworn friend of Pomona, and that he who robs the orchard feels justly her avenging gripe; I could forgive Dardner for catching me at the Gooseberries; for smiling many a time, as I have no doubt he did, when the doctor's gig drove up the avenue; for the remark he made, on the occasion of my reappearance after a somewhat serious seurfait, that "he was afraid the pretty bird who ate his Morello Cherries, had hurt his little beak against the stones;" I could forgive him so far, and I could forgive Nurse for putting me to bed; but to make me swallow that vile nauseous mess, as an antidote to a perfectly impossible stomach-ache, to treat me as one overcharged and plethoric, when I was as hollow, sir, as my own drum; you must agree with me—although the mixture did not—that no insult could have been offered to me with a worse taste, and you will be glad to be told hereafter that I had my revenge. And here, as the champion of injured innocence, I protest solemnly against that flaunting display of the Family Medicine Chest, which I have noticed in some nurseries. The position of our own was fulsome. Each morning it met my awaking sight, with its hard, cold stare of brassie insolence; and it shone in the firelight, when I lay abed at eve, as though polished with the Oil of Castor. The expression of countenance with which the nurses pointed to that box, was fiendish; and the way in which they unlocked it, and loitered over the preparation of its doses, was worthy of the Inquisition in its best and happiest days. Somebody filled the keyhole, on one occasion, with an unusual but ingenious combination of coal-dust

and batter-pudding; and somebody chuckled in his crib, you may be sure, when Nurse broke both lock and key.

Now let me propose briefly to my brother Spades and others a thought or two concerning the treatment of little children in gardens.

With regard to flowers, let children be taught from the very first to admire, to love, and to cherish them, not to regard them as temptations to mischief, and to connect them only with uneasy recollections of punishment. When Master Johnny decapitates his first Tulip, or brings in his first Hyacinth, roots and all, from the borders, don't treat him as an abandoned ruffian, and make him frightened at flowers for life; but show him with a calm and gentle tenderness the perfect beauty which his hands have spoiled, and tell him reverently Whose work he has undone. Let him draw near and gaze, where he may not gather; point out to him the symmetry, the tints, the perfume; remember that there are organs of Benevolence and Veneration, of Form, Order, and Colour, in the cerebral development of that curly pate, as well as of a Covetous and Destructive tendency; appeal to his higher, holier self, converse with the Christian that is in him; ignore what is evil (for he will understand your tacit abhorrence) until there is stern need of open censure; trust, instead of suspecting; talk to him of prizes, instead of prisons, patting his back with your open hand, instead of shaking your fist at him; and, as surely as Love and Truthfulness are better and stronger than Deceit and Hate, you shall find in that little heart such a sympathy with all things pure and beautiful, as shall bow your head in shame.

With regard to fruit, I should be inclined, I think, to deal with little children, as confectioners and grocers are said to deal with their newly entered apprentices, and to give them a free range. I should, simultaneously, forewarn them thus:—"Ladies and gentlemen, you are now at liberty to make yourselves ill as ill as you please. These sour Apples and unripe Plums are absolutely at your disposal. You will oblige me by abstaining from the green Gooseberries, until I have withdrawn a space, as the *cranch* is painful to my nervous system; but, subsequently, every bush is yours. Your meal will be followed by a variety of aches and pains, for which you have to swallow some of the nastiest medicines known. These Nurse shall bring to you in a large teacup. If you would prefer to wait until dessert-time, you can have some nice ripe fruit with Papa and Mamma, and a glass of Cowslip wine instead of Black Dose; but pray please yourselves. Good morning."

They would attend dessert, ultimately at all events, to a man. Bolts and bars tend only to enhance our longings, to excite suspicions in our naughty little breasts that fruits which are so strictly guarded must be of the most delicious order; and each small conspirator whispers to his brother, "It's rubbish, Tommy, about their being unwholesome: they only want them for themselves."

S. R. H.

(To be continued).

A Deadly Grass.—One remarkable fact connected with Queensland botany is, that a grass, which grows locally abundant in the more northern portions of the colony, *Aristida hygrometrica*, (R. Br.), is fatal to sheep, by reason of its long sharp tripartite awns getting entangled in the wool and ultimately piercing the skin and penetrating to the viscera of the thorax and abdomen.

Influence of Green Light on the Sensitive Plant.—An interesting experiment in the effects of green light upon plant growth is reported in the *Chemical News*. In order to test the effect of green light on the sensitiveness of the Mimosa, M. Bert placed several plants under bell-glasses of different coloured glass, set in a warm greenhouse. At the end of a few hours a difference was already apparent: those subjected to green, yellow, or red light had the petioles erect, and the leaflets expanded; the blue and the violet, on the other hand, had the petioles almost horizontal, and the leaflets hanging down. In a week those placed beneath blackened glass were already less sensitive; in twelve days they were dead or dying. From that time the green ones were entirely insensitive, and in four days more were dead. At this time the plants under the other glasses were perfectly healthy and sensitive; but there was a great inequality of development among them. The white had made great progress, the red less, the yellow a little less still; the violet and the blue did not appear to have grown at all. After sixteen days the vigorous plants from the uncoloured bell-glass were moved to the green; in eight days they had become less sensitive, in two more the sensitiveness had almost entirely disappeared, and in another week they were all dead. Green rays have no greater influence on vegetation than absence of light, and M. Bert believes that the sensitive plant exhibits only the same phenomena as all plants which are coloured green, but to an excessive degree.

THE INDOOR GARDEN.

PALMS FOR THE GARDEN.

(Continued from page 218.)

CHAMADEOREA GEONOMEIFORMIS (MEXICO).—A stiff plant, not very ornamental. Fronds, entire, wedge-shaped, nine inches by six, bifid.

C. GLAUCIFOLIA (MEXICO).—Fronds, regularly pinnate; pinnae, drooping, fourteen to eighteen inches long, curving up and down, acuminate; those at the point shorter and broader than the others. An extremely graceful and ornamental species, light and airy in appearance, and when mixed with plants having large foliage its effect is striking and beautiful.

C. GRAMINIFOLIA (GUATEMALA).—Allied to the last, but more slender in leaf and stem; foliage, very narrow. An extremely elegant species, but scarcely dense enough for general purposes.

C. LINDENIANA (NEW GRANADA).—Fronds, regularly pinnate, four feet long; pinnae, an inch and a half wide. A very beautiful plant, with gracefully arching fronds, suitable for central positions.

C. CASPERIANA (MEXICO).—Allied to the former, but differs in the fronds being more erect and leaflets longer. A good and noble species.

Chamadorea elegans.

C. CRUCIFOLIA (MEXICO).—Fronds, finely pinnate; pinnae, twelve to fifteen inches long, half an inch wide. An extremely elegant plant for table decoration, or for breaking the view without obstructing light.

C. DECKERIANA (SYN., STACHYPHORBE: MEXICO).—Leaf, simple, wedge-shaped at base, bifid at apex, thirty inches long; veins, prominent. Stiff-looking, but useful for mixing with fine-leaved plants.

C. ELATIOR (MEXICO).—Fronds, pinnate; pinnae, regular, shortening towards the point; stem, slender. An elegant plant for pillar ornamentation, or for decorating walls, the stem being flexible.

C. ELEGANS (MEXICO).—Fronds, pinnate; pinnae, regular, ten inches long. A fine decorative table plant; the fronds forming a beautiful dark green head.

CERATOLOBUS CONCOLOR (SUMATRA).—Fronds, recurved; pinnae, regular, dark green on upper side, under side, white, margin, tinted with a slight metallic hue; the fronds decrease in size, until at the

apex they are merely recurved spines; leaf-stalk clothed at base with sets of sharp thorns that decrease in number and size as they approach the top; stem, slender. In general appearance this palm resembles some of the species of Calamus, but it is coarser, and pushes up suckers from the base in tolerable abundance. Good-looking plants, but not suitable for moving about, as their spines catch hold of other plants and tear them.

C. GLAUCESCENS (JAVA).—Allied to the last, but larger. All the species are fond of heat and water.

CHAMELEOPS.—The whole of the species belonging to this genus are greenhouse palms, and may be distinguished from Latanias by the stiffness of their general aspect and the netted fibre at the base of the petiole.

C. EXELSA (SYN., ELATA: CHINA AND JAPAN).—Fronds, fan-shaped, cut nearly to the base; petiole, unarmed; stem clothed with strong brown fibre. A compact plant, and very suitable for conservatory decoration.

C. FORTUNII (N. CHINA).—Fronds, erect, stiff, forming the fourth of a circle, and bright-green; fibre at base of petiole, very dense. This palm has the character of being hardy, and in sheltered positions in our southern counties it will live out of doors; but in exposed situations it looks starved and miserable. As a greenhouse plant it is very ornamental, and in summer it may be exposed to any extent.

C. HUMILIS (S. EUROPE AND N. AFRICA).—Plant, erect; fronds, forming one-third of a circle; petiole, with small spines on margin. The whole aspect of this palm is greyish-green; it throws out shoots from the base in numbers sufficient to make it a dense bush. Single stemmed young forms of it make good plants for window and table decoration. It is nearly hardy.

C. MYSTRIX (SOUTHERN U. S. AMERICA).—Foliage, dense, dark-green, erect, cut nearly to the base; fibre at the base of the petioles very strong, terminated by a row of stiff bristles. A dwarf plant, of very stiff habit.

C. MARTIANA (NEPAL).—Erect and stiff, bearing considerable resemblance to the last-named species, except a little difference in the spines at base of petioles.

C. PALMETTO (SYN., CAROLINIANA: SOUTHERN U. S. AMERICA).—Fronds, forming half a circle, cut nearly to the base, glaucous; petioles, unarmed. A lax grower, and not very ornamental.

C. SERRULATA (S. WESTERN U. S. AMERICA).—Grows about two feet in height; fronds, glaucous, short, and stiff. Not a good palm for purposes of decoration.

C. STOURACANTHA (SYN., MACROCARPA).—There is a plant in gardens under this name, but it looks very like *C. Martiana*. J. CROUCHER.

(To be continued.)

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Climbers for Rafters and Walls.—Can you favour me with a list of really good climbers for both a stove and greenhouse, to grow up the rafters, or be trained on a wall?—N. B.—[The following are among the loveliest of known plants, and bloom freely with very simple culture: Greenhouse Climbers—*Acacia*, *Ricanea*, *A. dealbata*; *Cobaea scandens* variegata, *Habrothamnus elegans*, *Kennedy Marryatiae*, *K. nigricans*, *K. rubicunda*, *superba*; *Lapageria albiflora*, *L. rosea*, *L. r. splendens*; *Mandevilla suaveolens*, *Passiflora Campbellii*, *P. Clovesiana*, *P. Imperatrice Eugenie*; *Plumbago capensis*, *Rhynchosphermum jasminoides*, *Solanum jasminoides*, *Tasciona Buchananii*, *T. ignea*, *T. Van Volxemi*; *Tecoma jasminoides*, Stove Climbers—*Allamanda*, in var., *Bignonia venusta*, *Bougainvillea speciosa*, *Cissus discolor*, *Clerodendron Hauxwellii*, *Dipladenia amabilis*, *Hexacentris myrsinoides*, *Hoya carnosa*, *Passiflora amabilis*, *P. princeps* (racemosa), *P. quadrangularis*; *Stephanotis floribunda*, *Thunbergia Harrisii*, *Ipomoea Bonae Nox*

Plants for a Greenhouse with a North Aspect (see p. 223).—Your correspondent “F. S.” is quite justified in asking advice before he builds a greenhouse with a north aspect. My advice to him is, instead of one, to build two small houses, one a stove, the other a greenhouse; then, whatever kinds of plants he has they will succeed as in the stove he will have plenty of heat in which to grow them; and, as they come into bloom, he can remove them to the greenhouse. In the case of bulbs, how nicely he could get them into bloom at three different times, so as to prolong their flowering season; and the same may be said with reference to all other classes of plants. Of course, he would require one hot-water pipe in the stove more than in the greenhouse; so, rather than select a list of plants for a greenhouse, I would advise him to build a stove and greenhouse combined, then go to some nursery, and select plants to suit both houses. As to naming plants that would thrive in shade in a greenhouse, that, with the exception of Ferns, would only end in disappointment.—T. SOUTHWORTH, *The Gardens, Castle Head*.

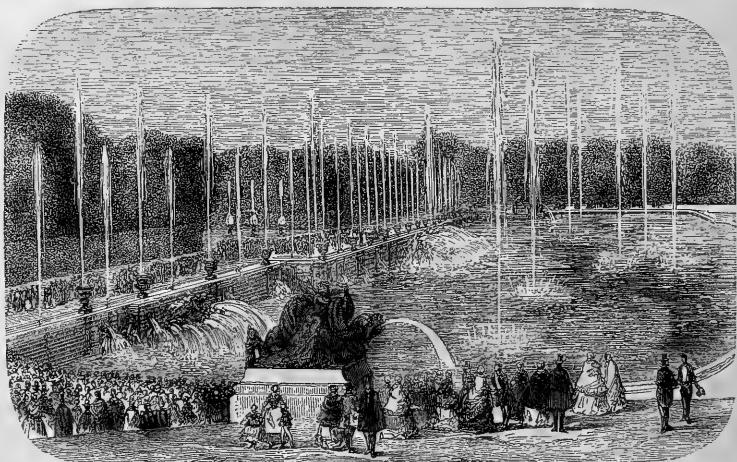

GREAT GARDENS OF EUROPE.

VERSAILLES.
BY NOËL HUMPHREYS.
(Continued from p. 217.)

The fountains of the celebrated Basin of Neptune are invariably those which on great occasions are the last set in action, and, enriched as they are by the most profuse and costly adjuncts of architecture and sculpture, they form the most splendid series of jets, cascades, and other devices that can possibly be conceived. A view of this grand final outburst of waters, which is always reserved as the bouquet for the close of the general display, may be best obtained from the back of the Fountain of the Dragon, as shown below, and may serve to convey some idea of the extent and magnificence of some of the effects produced when the *grandes eaux* are exhibited at Versailles, which never fail to produce upon all who have had the good fortune to witness the display, an impression of costly magnificence of which no spectators

been undertaken upon false calculations; and the great arches of the incomplete work now form a picturesque modern ruin. If, however, the project had proved successful, it is calculated that all the fountains at Versailles might have been kept playing every day from morning till night; but the royal intentions were frustrated by insurmountable obstacles. The smaller supply which was eventually obtained from the reservoirs at St. Quentin, Trappe, Feray, and other places; on the same high level as Versailles, and which is principally the collected result of an extensive system of superficial drainage, only enables the great series of fountains to be set in action for a very few hours at a time, and at certain periods only. The whole of those reservoirs, when at their fullest, are said to contain nearly eight million cubic metres of water; the average being something more than five millions. Of this supply nearly half is now required for the town of Versailles, the remainder only being available for the grand hydraulic displays in the gardens of the palace.

Of the restless constructing and destroying that took place, Saint Simon thus speaks, in relation to the expenditure at

Basin of Neptune, Versailles.

have ever denied the charm, however much it may have impressed upon them that the whole thing was in a spurious and semi-barbaric taste which they ought not to endorse. It must, in fact, be admitted that grand and impressive effects may be produced by various kinds of art, even those which modern theories cannot but denounce as spurious.

That such hydraulic displays, enhanced in effect by the adjuncts of elaborate sculpture, costly masonry, and plantations intended solely to increase the effect, were deemed the most princely kind of decoration by means of which royal gardens, and those of persons exalted by wealth or rank, could be rendered magnificent, may be conceived by the realised example afforded by Versailles. It is still more fully proved by the gigantic efforts of human labour and lavishly extravagant waste of millions which were expended in the futile attempts to bring the waters of the Euro to Versailles—a wild project which was attempted by means of the aqueducts of Maintenon. More than 30,000 soldiers were at one time employed on those vast works, which, when half completed, were found to have

Marly, which was almost as extravagant as that at Versailles—“Great trees,” he says, “were brought at enormous cost from the forest of Compiègne, and other places still further off, of which three-fourths died, which were immediately replaced by others. These were again sacrificed to make a space for new lakes, where courtiers amused themselves with Venetian gondolas, and the lakes were again transformed back into full-grown forests, which were expected to yield deep wooded shades, the very day they were planted.” It was the same at Versailles. The celebrated Labyrinth (a description of the original state of which was given in a previous number of *THE GARDEN*) was an extravagantly costly gee-gaw designed by the great painter, Le Brun, while Benserade furnished the inscriptions; yet it had to make way in 1755 for newer and still more costly objects, which were fortunately conceived in a somewhat simpler and better taste.

To describe all the other works, almost equally important, is not possible in an article which only pretends to afford a rapid glimpse of the general characteristics of the gardens of

Versailles, and to point out the defects of such a system of garden-making, as well as its excellencies, when they occur. There is, however, one more of these elaborate and costly decorations which cannot be passed over without a brief notice, as it is one of the most pleasing; and, to use a much abused term, much more gardenesque in character than most of the others. It is the Bosquet de la Colonnade and its architectural features that are here alluded to. This bosquet is an open space surrounded by a dense wall of foliage, in the centre of which rises a graceful circular colonnade, one hundred feet in diameter, every available portion of which is elegantly enriched with sculpture. These light arcades of white marble define themselves with charming effect against the dark background of foliage; and when jets of water are thrown up from the vases which alternate with the columns, and the scattered spray produces a slight mist which blends the forms of the edifice with those of the surrounding foliage, the effect is very fascinating.

There are not many instances in the formation of these gorgeous gardens in which the living greens and leafy forms of the trees are made to play an important part in the design: water, and marble wrought by the mason or sculptor, having the principal parts assigned to them in the vast composition. Those small portions of the plan which may be strictly called garden design, are extremely devoid of anything like inventive taste, and display a positive absence of any kind of natural effect, good or bad. To attempt descriptions of the Salle de Bal, the Queen's Bosquet, the Basin of the Mirror, the Saloon of Chestnut Trees, the Green Circle, the Etoile, the Domes, and other objects of analogous character, would only be a repetition of what has been said before. Immediately below the terrace are the geometrical parterres, which, however, perform a very secondary part among the fountains; and beyond these parterres extends the long green lawn known as the Tapis Vert, flanked by straight gravel walks of the same length. Beyond these, of equal breadth with the straight walk, extends the equally straight canal, enlarged at each end and in the middle by formal basins, and

crossed at right angles by another canal of somewhat wider dimensions. Parallel with the Tapis Vert and its lateral walks, other straight walks are formed behind the plantations, on either side; and there are transverse walks at right angles, cutting the plantations into large square patches, termed indiscriminately "bosquets." Each of these bosquets has some central object, such as the colonnade above described, a fountain, or a group of statuary, towards which diagonal walks converge; and this kind of disposition is again and again repeated where the breadth of the ground permits.

Below the Tapis Vert, after the canal commences, diagonal paths diverge through the plantations, as shown in our plan (p. 216); while in the grounds of the Grand Trianon the formalisms of the "bosquet" system are repeated, with little or no variation. The gardens of the Little Trianon, however, are in a totally different style; and will require a few words in our next issue in addition to what has been said of them in the first portion of this article.

The Colonnade at Versailles.

THE PROPAGATOR.

HYBRIDIZING PANSIES.

I HAVE been a grower of Pansies for many years, and my experience in regard to their improvement, by means of fertilization, may perhaps be useful to beginners. I select the best varieties I can find, and those most likely to yield something good and distinct for parents. I make my bed at the end of August, in front of a hedge facing the south-east. This bed is for early bloom. I cause it to be dug a spit deep, breaking up all lumps, and giving it at the same time a liberal coating of well-rotted horse-dung and road-sand. These, when well mixed, are dug in. In planting, I make a hole about a foot deep, and put into it about a handful of charcoal or cinders, as drainage. When the plants are well established, about November, I surface-dress with cocoa-nut fibre. This will be found invaluable for protection, and the plants will root into it in spring. This bed will produce fine early blooms, and if a few are required for exhibition, some old lights should be propped over them to throw off heavy rains.

For later bed, I choose a piece of ground by the side of a hedge facing the north-east. I make the bed of yellow loam, or the nearest approach to it I can get. I dig it well, and break all lumps; then I dress it with decayed leaves and rotten horse or cow dung: the last is best, if it can be had. These should be dug in and well mixed. The bed must be well drained, and not in a low situation. If the latter, use charcoal or cinders as directed in the case of the last bed. This bed will be found to be a fortnight or three weeks behind the other, but the quality and colour of the flowers will be superior to those in the early bed.

For the purpose of hybridizing, I select the best and earliest flowers I can find, and taking care not to injure any of the other organs, I remove the anthers from such flowers as I select to breed from. The flowers to be fertilized should be young, and the operation should be performed before the pollen grains show themselves, otherwise fertilization may take place while the anthers are being removed, and which is best done in damp weather. With a brush made of a few hairs out of a rabbit's tail, on a sunny day, I take the pollen grains from the flowers I wish to hybridize from, and apply them to the pistil of the flowers from which I have removed the anthers. When fertilization is finished, the flowers

should be, if possible, kept dry and free from bees or flies. The best plan is to cover them with a piece of thin muslin. All the flowers operated upon may not "take," but in a few hours those that have "taken" will be distinguished by a peculiar twist which the petals always assume. When the seeds come to be ripe, sow them immediately in pans well drained with charcoal, and in fine soil, with plenty of sand and leaf-mould in it. Keep them in a shady, cool place, and plant out as soon as the plants are large enough to handle. When the flowers are opening in spring and before any of them are fertilized, it is a capital plan to dust the bed with lime, which keeps off slugs and other pests, and thus often saves a pet flower from injury. Success, however, wholly depends on the care bestowed upon the plants, and none need expect to grow Pansies well unless more than ordinary interest is taken in their culture. In making beds for pansies some put a thick layer of cow dung under the surface soil so as to form a cool bottom for the roots to run in, a practice which succeeds admirably in warm dry situations; but in cold damp places it is apt to sour, and render the plants unhealthy.

E. S.

PROPAGATING YUCCAS.

In this operation it is best to begin with a good plant. If a large one is lifted out of the ground, it will be found that the root portion is studded with numerous elongated fleshy tubers, varying from three to five inches in circumference. All the exposed ones may be removed from the thickened root extremities without the least injury either to them or the parent plant. The specimen, after being denuded of its root-buds, can be again planted in good soil, and will go on thriving as if nothing had been done to it. It is not, however, necessary that the plant should be taken out of the ground for the purpose of removing these fleshy tubers. It can be done by simply baring the roots on opposite sides, and cutting the tubers off with knife. These fleshy root-buds, after their removal from the plant, can be potted, and placed in a gentle heat, keeping the apex a little above the soil, when they will soon develop a healthy crown from the extremity, also rootlets from the sides. After the tops have pushed a few inches, they should be removed into a cold pit or frame, and afterwards planted out in open-air beds, where they will soon mature themselves.

Another method of propagating the Yucca is by sections of the stem. When a plant branches, from the effects of flowering or by an injury, one of the branches may be cut off, and its stem cut into transverse sections, from one inch to one-and-a-half in thickness, and partially dried on the cut surfaces, by placing them upright in an airy position. They must afterwards be laid on the floor of a hot propagating pit, which has been previously covered with a layer of soil, over which a covering of sand has been placed, and afterwards kept partially moist. In a few weeks it will be found that the dormant buds round the cut section will swell, and finally push out into young growths, and roots will protrude from the lower side, which will penetrate the sand into the soil. After a few months the central portion of the section will decay, and the young plants will be left independent. When this takes place, they can be put round the inner surface edge of pots in good soil, where they will soon come forward, and, when strong enough, may be planted out in open-air beds.

The stems of Yuccas are formed by the decaying leaves annually falling, or what is more frequently the case, being pulled off. At the base of each fallen leaf, on the stem, will be found a scar; on the edge of each scar a slight swelling is observable, which, when detached, will develop into a young plant. On a free-grown stem, a section one inch thick will generally contain two dormant buds, and half an inch thicker will have about three buds. When cut thicker more buds may be given out; but they are not so easily handled as those produced from the thinner slices. While in very old, slow-grown stems, the scars are much closer together; and although the dormant buds are numerous, many of them never come forward. The development of these scars will not take place on the plant so long as the top remains; but if the top happens to be removed, it will be found that several of the scars nearest the upper end will develop into shoots. The superfluous ones can be removed, and treated as cuttings; they will soon root, and form independent plants.

When an old plant is furnished with numerous branches, it is easy to remove any of them in a state fit to grow, merely by cutting a notch about half an inch deep round four-fifths of the stem. After the cut becomes a little dry by exposure to the air, roll a quantity of damp moss round it, keeping it both above and below the notch. The under edges of the upper portion will soon callus over, and roots will be produced into the moss. When the roots are sufficiently strong, the stem may be cut on each side a little below the half-inch notch. In time the top may be cut off, and inserted either into a pot or in the ground. It will thus be seen that a few plants possess greater propagating powers than the Yucca.

In this country, so far as I am aware, the Yucca has never been known to produce seed, although seed is not unfrequently sent over from the southern States of America. Seedlings when procured, however, take a long time coming forward, compared with the methods of propagation just given. This is one of the not unfrequent cases in which a plant does not produce seed, but where nature has provided other means of increasing it.—J. M'NAB, in "Villa Gardener."

NOTES AND QUESTIONS ON PROPAGATING.

Anomalous Grafting.—In your number for December 30, 1871, p. 122, I find the following passage:—"Whoever wishes to study grafting in the works of celebrated ancient authors on horticulture, will find a string of absurdities, some of which we will mention. Virgil speaks of a plum-tree which bore apples after having been grafted, and recommends the grafting of the pear on the ash." I am unable to verify the first

assertion, as I cannot discover the passage; but is it an established fact that a plum tree cannot be grafted on the apple? As regards the second assertion, Virgil does not seem to "recommend" the grafting. He merely states (Georg. II., 71) that the *Orynus*—most probably *Pyrus aucuparia*—will produce the white flowers of the pear tree. Both these trees belong to the order Rosaceæ, as does also the almond, whose interbreeding with the pear M. Babet appears to doubt—W. O. CLEAVER.

Roses on Orange Trees.—Have you ever seen rose trees grafted on orange trees, and both flowering together? I used to manipulate them with success, and astonished our greatest botanists, who could not make out how roseworts could be united to otherworts. Should any of your correspondents like to know the method I employ, I will send it with pleasure, as I hate selfishness in all matters of horticulture.—J. S.

[We shall be greatly obliged if you will describe your plan.]

The Ash on the Oak.—The articles on grafting which have appeared in THE GARDEN have induced me to forward you the following account of what has come under my notice:—It has always been an axiom that there must be a close affinity between the stock and the scion. I accepted that without question till last summer, when my attention was called to a remarkable tree—in fact, a fine young ash which had been grafted on an oak. This had been done about two feet from the ground, and the line of separation was sharp and distinct between the two barks, although the character of the ash bark was slightly changed, seeming more rigid and unyielding than the ordinary condition; while both bark and wood had acquired the astringency of the oak, and when put in water, tinted it blue; and while the common oak trees were ruf of fruit, this was entirely destitute. Whether it ever blossoms, I cannot say, as I have not yet visited it at the proper season. The habit of the tree also seems modified, and, I think, improved, being more compact; the wood is much harder, though it does not seem to differ in structure. This tree is growing at Highland Farm, Ilford, Essex, and may be fifty years old, or probably more. Whether anybody at the farm knows the history of it, I cannot say. I have called your attention to this, so that you may invite some of your practical contributors to give the results of any experiments they have made, such as the grafting evergreen plants on deciduous, or the opposite process.—ALFRED GRUENEN. [What proof has our correspondent that the tree is grafted on the oak?]

Grafting Bignonia radicans on the Catalpa.—A correspondent of the *Horticulteur Français* announces the successful grafting of Bignonia radicans on the Catalpa. Some of the branches were headed back, and the Bignonia scions inserted by cleft-grafting. The result was, that from the midst of the luxuriant foliage of the Catalpa emerged numerous flowering branches of the Bignonia.

Preparations for Grafting.—Professional French grafters who make four amongst the farmers, often find prepared grafts dried up or otherwise injured. To avoid such accidents the following plan has been adopted with excellent results:—The cuttings are first wrapped in rags, in order to prevent the soil from mixing with the scions, and attaching itself to their bark, and then the packets are buried in a cold spot, to the north of a wall, at a depth of eight or nine inches; and, in order to prevent the scions from being injured when unearthed, a few branches are laid upon them. Scions thus treated, whether cut in autumn or in February, will keep perfectly till the end of April, if not later. The rule is, that at the time of grafting the sap should be rising in the stock, and about to do so in the scion; if the latter is cut at the moment of grafting it may be more forward than the stock, in which case the graft will fail. By cutting the scions previously the movement of the sap is stopped, and if they are then laid under ground the retardation may be carried to such an extent that they may be applied to stocks already in leaf, which is a great advantage where many graftings are to be made, whereas if the buds of the scions are much developed success is very doubtful.

Seeds and Weeds.—So full of seeds of various kinds is the ground in spring that when we sow a crop of any good seed, flower or vegetable, it is sometimes difficult to distinguish the crop from the weed, and both are allowed to grow up together. To obviate this, seeds should not, as a rule, be sown broadcast, but in drills or little lines or circles, according to kind and taste, and then, when they come up, it is easy to separate the sheep from the goats.

Raising Seeds.—Do such seeds as Aralia, Canna, Cassia, Chamaerops humilis, &c., Chorozema, Champepe, Solanum, Dracena, and ferns, quoted in catalogues as greenhouse plants, require a stove to start them, or can they be grown in a small greenhouse?—R. W. PARRY, JUN.—[All, except the ferns and the Chamaerops, would be the better for being started in a heated or warm propagating house or stove, although some of them grow very rapidly, as the Cannas and Solanums; Chamaerops raise with the half hardy annuals; ferns raise in a moist shady stove, unless they are hardy kinds, in which case, a moist frame or pit will suit them.]

A New Cure for the Currant Worm.—Our friend Hick Cupps, Esq., of Harfseysover, drops us a tear and a line, enclosing this paragraph:—

"A Connecticut man has found a sure cure for the devastations of the currant worm. He sprinkles his bushes with whiskey; the worm becomes drunk, gets to feeling around, and finally falls off, and either breaks its neck outright, or cripples itself so that life becomes a burden." He says this is a melancholy waste of whiskey to preserve a few berries remarkable words, it is "throwing a spratcoker to catch a mat (sic)."—Tun.

GARDEN DESTROYERS.

THE PINE-BORING BEETLE.

(*HYLURGUS PINIPERDA*.)

THIS is a small, purplish-black beetle, which, both in its larval and perfect state, does much injury to different species of pine trees. It is to it that the brown and withered leaders and shoots which are often to be seen on these trees are generally due. In the north of Europe it ravages the woods of *Pinus sylvestris*. In the department of the Landes, where the *Pinastor* (known there as the Maritime Pine) predominates, it specially attaches itself to it. In this country we know that it attacks various kinds of pine. *Pinus austriaca*, for example, is preferred to the Scotch fir; and *Pinus insignis* is liked better than either. It has also been observed, either in this country or in Belgium, upon *Pinus pinifolia*, *P. laricio*, and *P. brutia*. I no doubt also on others which have escaped record. This is the earliest of the Xylophagous beetles. In the north of Europe, according to Ratzburg, it appears in the month of March. In the south of France it is to be seen in the first fine days after the depth of winter; and from the month of January, after two or three days of sunshine, one is certain of finding it already occupied in boring the bark of pines that have been felled or are sickly, as well as stumps remaining in the ground. Here it is little seen before May. It discloses its presence on the trees by the little heaps of rotten wood which the larva casts out of its galleries. It is the fresh liber of the plant that forms its food, consequently those trees whose liber is too much dried up are disregarded. Those which they attack are sometimes so full of sap that an abundant flow of the resinous juices follows their boring, which hardens into the form of tubes of greater or less thickness around the orifice of invasion. It is indifferent as to the age of the trees. From their tenth or twelfth year, until their most advanced age, they are subject to its attacks; but it is rare to meet with it in trees under ten years old, the reason of which, without doubt, is that these do not offer sufficient space for the development of the insect.

GALLERIES.

The hole by which it enters is oblique, and the principal gallery, always simple—that is to say, without ramifications—extends longitudinally above and below this entrance hole, forming at the furthest end at each side a small curve, whence it proceeds in a straight direction. It is supplied with from one to four air holes. We usually find both the male and the female in this gallery; but never more than one individual of each sex, and rarely the female alone. The eggs are deposited in little notches like those of the *Bosstrichi*, and the galleries made by the larva are winding and transverse, except when the diameter of the tree is considerable, when they end by becoming oblique or longitudinal. These galleries are hollowed out, like the gallery for eggs, in the liber in contact with the cambium, which, however, they never touch. They detach the bark completely, making it easy to lift it in large sheets. It is unnecessary to remind our readers that the cambium and liber are the layers which separate the wood from the bark, the cambium being the layer outside the wood, and the liber that inside the bark. The metamorphosis into the pupa takes place in the bed of liber or in the bark.

LAYING AND HATCHING OF EGGS.

As soon as it appears after winter the *Hylurgus piniperda* invades the trees or timber which it selects to nourish its offspring. The gallery for the eggs is pretty quickly hollowed out; but the emission of the eggs rarely follows very soon after the completion of this work. The occurrence of warm days in spring often determines the laying of the eggs, but the cold and varying weather which frequently succeeds keeps the hatching back, and when at last the larva do come out, the recurrence of similar causes may retard their development. It is not until the month of May or June that the development becomes rapid, seconded as it then is by the length of the days and the higher temperature. The grubs then grow quickly, pass into the pupa stage, and the perfect insect takes to flight in June or the beginning of July.

PROCEEDINGS OF PERFECT INSECT.—TERMINAL SHOOTS ATTACKED.

Next comes the time when it forces itself on our attention by destroying the young shoots of the trees. Hitherto it has not touched them. It has been occupied with the food under the bark of solid, thick trunks or branches. Now, in the perfect state, the liber which served for a sumptuous diet to the larva, is not good enough for it. It must have the fine pith of the young shoots still in the herbaceous

state. It has been said that it sometimes will go farther back on the branch, and begin at the two or three year old part. But this must, we think, be a mistake. Its gourmand proceedings soon show themselves, and the brown, withered, hanging, or broken shoots disfiguring our trees tell us that their enemy has been at work. This continues during the whole summer until September.

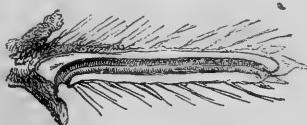

When we come to examine the mischief, we may generally perceive one of those short stalactites of hardened resin which are produced by the exudation from tissues ruptured by insects. If we search for the cause, we find that these withered shoots or twigs are hollow, the medullary substance having been eaten out. In the interior of the tunnel so made, which is frequently prolonged to the terminal bud, we may generally find a *Hylurgus piniperda*. If it is found to be

The Pine-boring Beetle and Grub.

empty, it is because the insect has left it; but, in that case, we may sometimes notice below the entrance hole another by which it has made its exit. More frequently there is only one hole; which goes far to prove that the insect has both entered and gone out there. It is not unusual for two individuals to establish themselves in the same twig. There are then two orifices for entrance at different heights, and the two galleries do not usually communicate with one another, because the lower *Hylurgus* stops its work before breaking through into the upper tunnel.

The insect seems to pass freely up and down its tunnel—and, indeed, it keeps it clean swept and garnished; and this furnishes the easiest and simplest test by which we can distinguish its work in these young shoots from the work of some species of small moths that attack the pine shoots in the same way. Curtis quotes an observation of Dr. Lindley on the mode of the *Hylurgus's* work, which illustrates this:—"For the purpose of observing its proceedings more narrowly, I placed a shoot of the Scotch fir under a glass with the insect. In about four hours after, its head and thorax were completely buried in the shoot, and it had thrown out a quantity of wood, which it had reduced to a powder, and which nearly covered the bottom of the glass. In sixteen hours more it was entirely concealed, and was beginning to form its perpendicular excavation, and was busily employed in throwing back the wood as it proceeded in destroying it." Consequently, in the bored shoots formed by the *Hylurgus piniperda*, there is no detritus or excrement; whereas, in the shoots bored in a similar manner by the *Tortrix*, the gallery is encumbered with excrement. And the reason of this is not any greater love of cleanliness and tidiness on the part of one insect than the other, but simply that, in the case of the *Hylurgus*, the tunnel is excavated by the perfect insect itself, and not by its grub; whereas, in the case of the *Tortrix*, it is the grub that makes the excavation. The former has greater freedom of action. The grub, as usual, eats straight forward, choking up the passage behind it with the detritus and debris of its workings, so that returning would generally be as tedious as beginning afresh.

Shoot Bored by Pine Beetle.

The excavation of the shoot is one of the points in the history of the *Hylurgus* on which it is common to hear a difference of opinion. Is it really done by the perfect insect, or by the grub? Certainly, it is by no means an uncommon thing to find a grub in the perforation; but then that fact is not enough. The perforated shoot may not be the work of the *Hylurgus*, or the grub may not be its grub. It may be that of the *Tortrix* or something else. One of our friends, a very acute observer, states that he has frequently found two grubs in the same tunnel, and he thinks even more. Equally strong is his statement that he has frequently found the pupa in perforated shoots. But then the pupa was not the pupa of a beetle, but of a moth. There are other collateral circumstances which are opposed

to the idea of the grub of the *Hylurgus* attacking the terminal shoots.

INJURIOUS EFFECT OF LEAVING THINNINGS, ETC., LYING ABOUT.

One circumstance is that it has been observed that the insect is much more frequent and destructive in woods where recently cut wood, or thinnings or prunings, are left on the ground, and that the same result follows the putting up of palings of Scotch fir, recently cut and not dried or seasoned. The grub, as already mentioned, feeds on the liber of the pine while fresh, and full of the natural sap of the plant. As the reader knows, this continues fresh and liquid for a considerable time in the pine (at least twelve months), and it is better adapted for the use of the insect during these one or two years than either before or after. After it has turned into actually dead wood, it will not do at all: their food is fresh meat. While still part of a healthy and vigorous tree, it suits them better, but not absolutely, for the resin is apt to overflow them and drown them. Into the bark of such trees the *Hylurgus* is slow to enter, and where it has done so the observer will find specimens embalmed in resin. They are free from such an inconvenience when the connection with the seat of life and growth is severed (but not too long severed), as in recently felled trees and pruned branches, or where the health of the tree is retrograding and its circulation languid, and such form a suitable nidus for the insect—a sure focus of infection—the centre from which the insect spreads around. This is well recognised among foresters.

Thus we have a communication from a correspondent near Ware, Herts; who says:—“There is no grub in the young plantations here, though there are many Scotch firs and austriacas as well; but there is none for fencing in this place.”

Another correspondent remarks, that while his plantations have suffered from the *Hylurgus*, it does not appear to have attacked much larger woods which surround his property. But his plantations are almost part of the shrubberies and garden around his house, and are much cared for, carefully thinned and pruned, and there is always some dead timber thus provided for them as a nidus, while in the larger woods around him there is nothing of this provision.

Again, “The beetle has invariably decreased with us (Warbrook, near Eversley, Hants) after the clearing away of the old dead wood, and where no trees have been taken down it has not appeared.

M. Perris cites a similar illustration. He says:—“Around a recently constructed limekiln, a very considerable quantity of recently felled pines were stored which were severely attacked by *Hypiperra*. By the side of the limekiln there was a group of pines about fifty years old, separated by a distance of from three to four hundred yards from the neighbouring forests. The pines, which had served for the propagation of the *Hylurgus*, gave innumerable swarms of these insects, which, having at their door the pines of which I spoke, threw themselves upon them *en masse*, attacked almost all the branches, and produced such an effect that in the month of August the trees appeared dried up, and after a storm the ground was strewed with broken twigs and the branches fringed with them. I was then consulted, and I confined myself to advising the proprietor of the limekiln and the pines not to store up wood which had not been felled more than a year, or remove the bark of that which had been felled recently. These precautions having been taken, the mischief was not repeated in the following year, but the trees showed only a languishing vegetation and gave very little resin. The year after they were rather more vigorous, but it was easy to see that they were merely in a state of convalescence. I consider it a piece of good fortune that they escaped the attacks of the *Xylophages*, and that the proprietor had not to suffer from his imprudence.”

It has been a question with some authors whether or not the *Hylurgus* passes the winter in the perforated young shoots, but it has been definitely resolved in the negative. Raizeburg, Chevandier, and Perris, all assure us that they have found the insects sometimes in great numbers gathered together round the neck of the roots of large living trees. They hide in the crevices of the bark, or bore as far as the liber, only to make themselves a shelter.

DESCRIPTION.

The grub is about three lines in length, whitish or yellowish white, except the mandibles, which are ferruginous, turning into black at the tip. Its body is curved, and thickest at the thorax. It has no eyes and no legs or feet, but in their place two series of retractile nipples under the three thoracic segments, and a double little tubercle along each side. The number of its stigmata is nine pair.

The perfect insect is black or purplish black, unless when newly or prematurely disclosed, when it is chestnut coloured, or more or less pale. Our illustration represents it, and therefore renders a detailed description unnecessary.

The prevention and cure of this insect has been pretty clearly indicated by the details we have just given. The prevention is obviously to be careful to leave no recently cut pine wood or branches littering the ground. Paling made of fresh cut pine wood with the bark on ought to be eschewed. Old wood seasoned and barked is harmless, and when the insects have reached the perfect stage and attack the young shoots they should be picked and burned or otherwise destroyed.

A. M.

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

Town Garden Plagues.—I have a garden about half an acre in extent in the centre of a town, and this little oasis, which has been trenched and manured until the soil is extremely fertile, is infested by the following plagues:—First of all, hundreds of cats make it their rendezvous, and, in the spring time, sharpen or clean their claws in the hearts of my finest cabbages. Every butterfly within five miles concentrates her reproductive powers on the leaves of my plants, which are, consequently, a mass of insects as soon as they show a leaf. Chaffinches and sparrows in clouds descend upon the early peas, pick off every cotyledon as it shows itself, and root up sometimes the seed from the earth. The only certain crop is that from the gooseberry bushes; but even on these the points of the berries are mostly covered with aphids. I have slain so many cats, that I can scarcely find room for their carcasses.—W. M.—[A good way of keeping cats out of town gardens has been given at p. 114 of THE GARDEN.]

Worms on Lawns.—“J. B.” (p. 255) should keep a pair of Green Plovers (Pewits). I have found these birds a sure remedy; they hardly ever cease eating whilst a worm is to be seen; they must be driven in at night, or the cats will come after them. In the day time there is not much fear; for if puss comes too close, they will call out loudly for help. When worms are scarce, put near their water-trough a little chopped meat, or some bread-crumbs mixed with hot dripping—one wing must be kept clipped. In addition to their very active services, these birds would be interesting and attractive pets for many years; they cost about three shillings and sixpence each.—G. T.

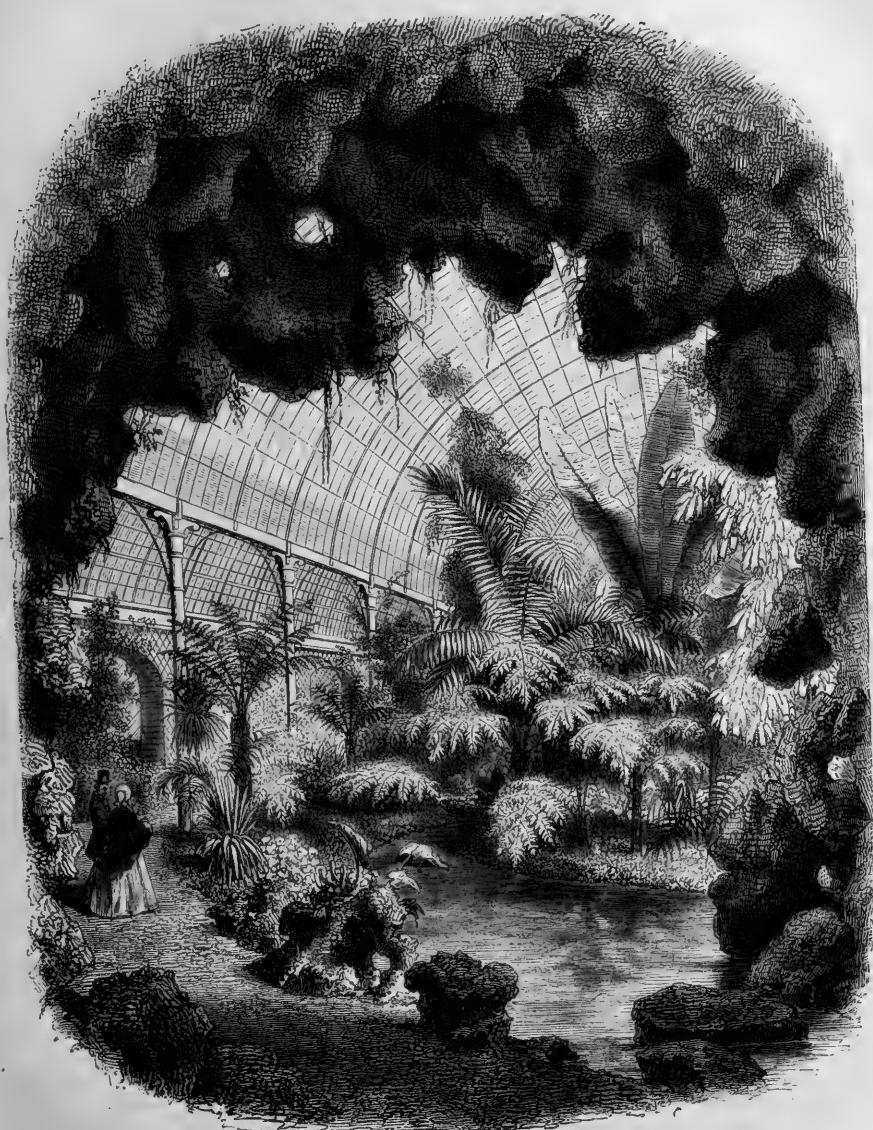

CONSERVATORIES IN THE NATURAL STYLE.

A COOL HOUSE.

In a preceding article (p. 181) we have given consideration to the laying out of a winter garden or conservatory for plants belonging to the warmer regions of the world, and have grouped together such representatives of tropical vegetation as can exist in the same atmosphere. The only exceptions which we have made to this rule is in the case of some greenhouse kinds which acquire larger dimensions under the influence of a more intense heat than they would in a cooler atmosphere, such as certain Palms, Araias, &c. For instance, the Rice-paper plant, which grows in the open air in the south of France, acquires gigantic dimensions in a hothouse. A specimen of it, thus treated, measured thirteen feet two inches high, and threw out magnificent leaves, exceeding six feet six inches in length, including their stalks.

In most cases, nevertheless, the plants named for a greenhouse suffer under too high a temperature. Besides, the cool winter garden is still more valuable than that which we have already placed before our readers, inasmuch as it is as rich in ornamental specimens, and more within the reach of moderate means. Very little artificial heat is enough to keep the temperature in winter at a minimum of three degrees above the freezing point, which is quite sufficient for the period of repose which is required for many of the plants from Australia, China, Japan, New Zealand, and mountainous tropical regions, &c. One can hardly believe what numbers of plants there are, often supposed to belong to tropical climates, with which a cool conservatory can be furnished. Numbers of our beautiful Palms would yield to cool treatment; and hundreds of Ferns require no better situation than the shelter of glass. The Dracaenas, Agaves, Acacias, Dasylirions, Ficus, Araias, Banksias, tender conifers like the Norfolk Island Pine, Yuccas, Grevilleas, Rhopalos, and the Cactuses, would certainly submit to the same treatment, without mentioning the smaller kinds, which only thrive under a low winter temperature.

The experience acquired of the natural style of arrangement in conservatories during fifteen years in Europe, enables us to recommend it with confidence. The treatment carried out in reference to some tropical species has often no relation to the altitude at which the plants naturally grow. Should a plant

COOL CONSERVATORY IN THE NATURAL STYLE.

arrive from Mexico, it would naturally be placed in a warm conservatory. But as regards the Ferns of that country, they are found between 3,600 and 6,000 feet above the sea level, that is to say, at the limit where begin the Pines and Heaths of the sub-alpine region; and it is at this height that the magnificent Alsophilas spring up.

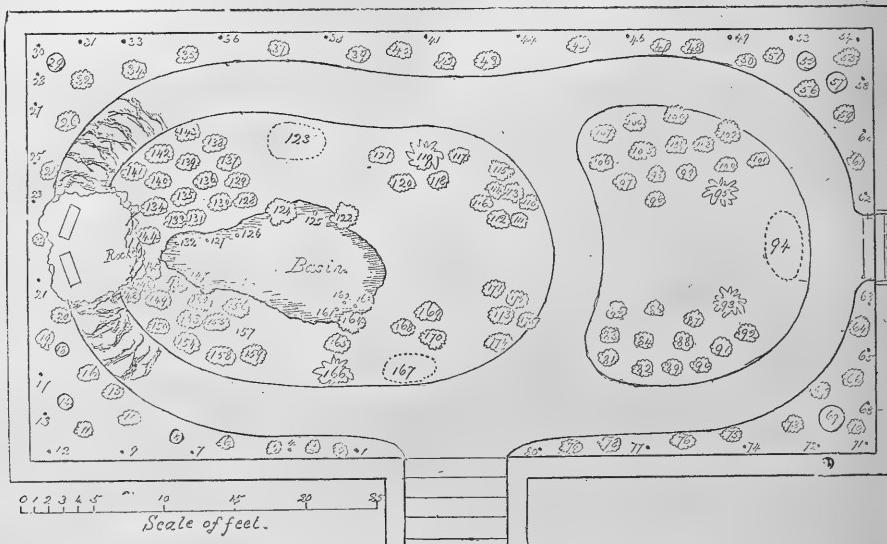

More than thirty Palms now flourish in our cool houses. A great number grow in the cold regions of tropical mountains, such as the Ceroxylon andicola, which is found at 10,000 feet and upwards. The Oreadoxa frigida, and several kinds of Chamaedorea, rise up to the Pine region; the Areca humilis reaches to 8,000 feet in Java; the Chamaerops Martiana to 7,800 feet in Nepal; the Phoenix humilis to 6,000 feet; without reckoning the Chamaerops excelsa of China, the Rhipis fibelliformis of Japan, Corypha australis, &c.

Let us now proceed to plant a cool house on the plan already used in the case of a warm conservatory. By the aid of numbers, we can at once show the different types of vegetation that may be used in each case. Our large illustra-

Permit me now to give a list of plants with noble leaves, and of stately port, that thrive well in a cool house:

67. Chamaerops stoura- cantha	90. Oreadoxa frigida	136. Seaforthia gracilis
15. Chamaerops excelsa	173. Phoenix tenius	142. Chamaedorea glau- cifolia
32. Corypha australis	163. Cocos Romanzoffii	137. Chamaerops Martiana
55. Jubaea spectabilis	159. Areca Sapida	118. Phoenix sylvestris
102. Sabal palmetto	166. Glaziova elegans- simis	105. Cocos australis
105. Phoenix rufa	154. Cyrtostachys renda- nica	95. Phoenix tamarindina
95. Rhipis fibelliformis	156. Cyrtostachys elata	105. Chamaerops humilis
93. Livistona sinensis	149. Seaforthia elegans	102. Brachia nitida
84. Seaforthia robusta	134. Brahea dulcis	

Here, then, are twenty-six kinds of Palms, more or less high, which will thrive perfectly under the temperature that has been named, and which will form a background of foliage of supreme elegance. We speak of such only as have been proved to succeed; and if the altitudes at which they grow spontaneously are compared, it will be seen that a conservatory with a minimum of 38° Fahr. is all that they require. It is known that for every six hundred feet of altitude above the

Ground Plan of a Cool Conservatory in the Natural Style.

tion will convey a faithful picture of the general aspect of vegetation that may be obtained in a large, slightly-heated structure. We will first give a list of climbing plants, without which no such structure can be properly adorned:—

- Rhynchospermum jas- 25. Mandevilla suaveolens 53, 54, 58. Aristolochia minoides
- Plumbago scandens 27, 28, 30, 31. Senecio 60. Kennedya Myrsinaceae
- Dessistoria carroliae
- Mimulus luteus 33. Tropaeolum speciosum
- Solanum jasminoides 33. Tropaeolum spathifer
- 12, 13. Solanum jasminoides 33. Tropaeolum edule
- Cocca scandens varie- 41. Aristolochia semper-virens
- Thunbergia laurifolia 41. Aristolochia semper-virens
21. Thunbergia rosea
23. Kennedya violacea
54. Aristolochia edulis
55. Bignonia Cerereana
56. Bignonia

Among the Tree Ferns, the following are suitable for the conservatory:—

121. *Alsophila australis* 116. *Alsophila ornata* 170. *Cyathea dealbata*
82. *Blechnum brasiliense* 110. *Balantium antarcticum* 151. *Todea australis*

With plenty of space one might add:—

- | | | |
|------------------------|-------------------|---------------------|
| Alsophila excelsa | C. spectabile | Lomaria cycadifolia |
| Balantium Culcuta | Cyathia modularis | L. gibba |
| B. Sellowianum | C. Smithii | L. discolor |
| Blechnum Rio-grandense | Dicksia fibrosa | L. magellanica |
| Cibotium regale | D. squarroso | |

The following plants, though not so important, deserve a place by the side of these, such as:—

106. *Cordyline indivisa* 107. *Camellia japonica*, ss. *Camelia*
97. *Podocarpus* 108. *Vaccinium* 93. *Kempii*
90. *Podocarpus* Tolara 86. *Psychotria* Mario Bell-
99. *Clivia cyathiformis* anger
100. *Correa cardinalis* 87. *Francoa sonchifolia* 86. *Cineraria capensis*
101. *Farfugium grande* 92. *Edwardsia grandiflora* 83. *Brugmansia sanguinea*
104. *Eucalyptus viminalis* flora 91. *Sparmannia africana* 91. *Daphne delphinii*
109. *Eleagnus undulata* 104. *Clivia nobilis* 93. *Camellia* cana

In order to make intervening spaces a little ornamental, an infinite number of less important plants could be added.

We next come to plants for decorating the beds of the central portion. For the grass plot may be taken:—

174. *Pancratium mexicanum* 121. *Rhododendron* Jen. 134. *Thea viridis*
121. *kinnsii* 121. *Platycerium grande*
175. *Sedum spectabile* 122. *Araucaria excelsa* 143. *Scenecio platianthoides*
177. *Aspidistra elatior* var. 123. *Lomaria gibba* 146. *Nephrolepis exaltata*
139. *Asplenium* 130. *Acmaea tuberculata* 148. *Asplenium lamprophyllum*
171. *Agave Verschaffeltii* 129. *Chrysanthemum* 150. *Pteris cretica* albo-
112. *Phormium Colensoi* 129. *Comte de Chambord* 151. *Argosyus sinuatus*
111. *Philesia buxifolia* 130. *Crown salicina* 152. *Cyrtomium falcatum*
100. *Macleania cordata* 143. *Aspidium Bellangeri* 155. *Acacia dealbata*
113. *Linum trigynum* 135. *Stachydium australis* 156. *Pimelea elegans*
114. *Eucalyptus gigantea* 142. *Mimosa cultiformis* 157. *Thlaspi glaucum*
115. *Aralia Siamea* 142. *Sarcococca africana* 158. *Senecio Ghiesbreghtii*
116. *Sarcococca oblonga* 143. *Eucalyptus cana* 164. *Musa Ensete*
118. *Thulopsis dolabrata* 135. *Eucalyptus gigantea*

Plants between the borders and the glass may consist of:—

2. *Wigandia urens* 26. *Verbena citriodora* 55. *Redocarpus zamiaefolius*
5. *Yucca aloifolia* tri. 29. *Magnolia fuscata* 59. *Phyllocaetus Akermanni*
69 or 70. 34. *Aralia dactylophylla* 61. *Fuchsia var.*
5. *Woolverardia radicans* 35. *Saxifraga macrophylla* 64. *Aralia nerifolia*
9. *Jaborosa suspensum* 37. *Templetonia retusa* 66. *Osmanthus ilicifolius*
9. *Xanthorrhea hastifolia* or 39. *Siphocampylus Humifolius* 69. *Geopinus platani-*
10. *Veronica Andersonii* 40. *Solanum latiflorum* 70. *Bocconia frutescens*
var. *veraefolia* 42. *Monnieria heterocarpia* 73. *Helianthus major*
11. *Acacia lineata* 43. *Clivia minata* 75. *Aralia papyrifera*
14. *Abutilon striatum* 43. *Salvia (various)* 76. *Hebeclinium macrophyllum*
16. *Hibiscus rosa-sinensis* 47. *Rogeria gratissima* 78. *Hedychium gardnerianum*
18. *Aralia pubescens* 49. *Rhododendron Gibsoni* 79. *Desfontainia spinosa*
19. *Senecio Ghiesbreghtii* 50. *Azalea amena* 81. *Bombus australis*
20. *Nicotiana wigandii* 50. *Azalea australis* 82. *Rhododendron Nut.*
22. *Bambusa Fortunei* var. 51. *Alpinia purpurata* 83. *Malus*
rigida 52. *Rhododendron* Nut. 70. *Desfontainia spinosa*
24. *Viburnum Arrafuski* 57. *Pleroma elegans*

GENERAL TREATMENT.

The Palms for a winter garden ought to be kept in pots up to the period when their leaves divide and show their character and their stems become at their base as thick as the arm. They must not be put in the ground before this, nor until they shall have been frequently repotted and have been kept as much as possible in a warm greenhouse where the pots have been plunged in tan. They should be repotted twice a year, in spring and summer, when their growth is rapid, without cutting the roots, and in pots deep and narrow. A quiet and warm atmosphere, somewhat shady, but without stagnant moisture, is best suited to Palms when young. Growing Ferns have nothing to fear from the open air or the sun; it is only the stemless kinds which flourish in the shade and under other plants, their roots requiring nourishment. The *Alsophila australis* may be placed outside in the full sun without injury; if it be watered from time to time with liquid manure it will acquire considerable dimensions in a short time and be of unsurpassable beauty.

A great number of the plants named will remain uninjured if protected from the frost; but it is better, as has been already said, to keep up the winter temperature a little over the freezing point; and even when the sun strikes upon the glass, raising the temperature, it will not be necessary to open the house at all during the winter. After February however, when vegetation is getting active, it will be necessary

to give air gradually and to water in the evening. In March you must begin to shade with some light material up to the time that you can uncover the greater part of the conservatory, and at last place some of the plants in pots or boxes in the open air. As to the great Palms and Tree Ferns, Dracanas, Aralias, &c., they will be better slightly shaded throughout the year, taking care to give plenty of air. Where it could be easily done, it would be desirable to remove the roof and allow the contents to be refreshed by the summer rains. Thus managed, with plenty of water and a proper amount of shade, it is very possible to develop splendid vegetation in such a structure.

Here, then, is another example of a winter garden in the natural style. Should the readers of THE GARDEN take some interest in the matter, we may, at some future period, show how it may be suitably varied by tropical plants, hothouse fruits, and medicinal plants.

ED. ANDRÉ.

THE FRUIT GARDEN.

POOT CULTURE OF THE FIG.

To those who are fond of this fruit, and have no means of growing it either planted out in a house or in the garden, its culture in pots is peculiarly useful. It will be found that the essentials necessary to success are very simple, especially where there is a pine stove or cucumber house at command. The roots must be kept in a very confined condition, and moist; the leaves, by syringing, kept clean and healthy, with an atmosphere free from aridity until the fruit arrives at the ripening process, when they must be placed in a medium of heat, airiness, and comparative dryness, as the fruit is liable to rot if allowed to get wet, and in a humid atmosphere it would be deficient in flavour if allowed to ripen therein. The fig is very impatient of stagnant moisture at the roots, and at certain stages of growth more so than at others. Therefore, to prevent as far as possible any mischief from this cause, it is requisite to make the drainage perfect, so that it may last good, if need be, for two successive years. The compost also ought to be of perfectly open and free character, and at the same time manurially rich enough to afford sustenance for a lengthened period; a gritty, fibrous loam four parts, sound manure one part, and a few half-inch bones added, would make a good compost. The pots in the growing season ought to be placed on bricks, so as to allow the water which may drain through the bottom of the pots to clear away, thereby conducing to the healthiness of the trees. Where there is not much room in which to grow them, fresh batches should be periodically propagated, and the largest of the trees should be thrown away.

As early now as possible, eyes should be put in, either singly in three-inch, or a number in larger sized pots, covering the buds not deeper than half an inch with the finest of the compost used, which ought to be free from anything likely to cause the roots to break when potting them off. In a brisk hotbed the emission of roots occupies but a short time, and shortly after this is the case pot off into five-inch pots, and place them in a position where they will have plenty of light, and a warm, hard bottom to stand on. Be sure not to water them till the compost—which ought always to be moist when used—has become dry; otherwise, if watered before, the roots will rot, and the plants in consequence die. After the first watering, the plants ought never be allowed to get dry, but kept constantly moist; this applies to succeeding repottings as well. Seven-inch pots are the size required for the next shift, then nine-inch, and for the largest plants another remove into eleven-inch pots will be required. Those pots which are intended to stand over the next year must be thoroughly drained; the smaller sizes require but little. By pinching the points out of the plants when nine inches high, paying attention to stopping the side branches at every fourth or fifth leaf, and tying them down horizontally, so as to afford the greatest possible room for leaf development, and a greater number of shoots to fill in the centre, neat bushes will be formed. After this, all that is required is keeping the shoots pinched, thereby inducing fruitfulness, thinning the crops down to a moderate quantity on each bush, and shifting them into pots two sizes larger than those previously occupied. In performing this operation, gently prick the ball round the outside, to get rid of any soured soil; pot in all cases to the same depth, and ram the soil quite firmly in round the ball. Place them in a moist, warm temperature, keep well supplied with water, and ply the syringes to prevent flagging; when roots have commenced working in the new soil, remove them to a warm position out of doors, standing them on bricks; from thence to be moved into a house, where no danger from frost need be apprehended. The best time

for shifting into larger pots is immediately after the last crop of fruit has been gathered, fifteen-inch pots being large enough for any of them. When it is thought necessary to shift bushes in this size of pot, chop off an inch from the ball all round, and treat them as advised for other pottings. Weak manure water is beneficial when the pots are thoroughly well filled with roots, but not unless this is the case. It is also the usual practice to surface-dress the pot at intervals; but this I cannot recommend, as either an overdose or a scant supply of water is generally sure to follow, either of which is exceedingly hurtful to the well-being of the fig.

If the trees are required for forcing, commence with a temperature of from 50° to 55°, increasing it as the buds break into leaf. When in full leaf, a temperature of not less than 65° must be allowed them at night, with a proportionate rise in the daytime. As the plants progress, an increase of 10° may be made with advantage. By commencing with a few in the beginning of January, and judiciously managing the stock of trees, a continued supply of ripe fruit may be secured from the middle of April on till autumn. Care must be taken to keep the trees from getting dry during the winter. Plunging the trees, where possible, is the best means of attaining this end, and has the additional advantage of securing to the root a comparatively even temperature. The brown Turkey fig is the best variety for pot culture that I have had experience with, the great fault of many sorts being the bad habit they have of casting their fruit. The flavour of the brown Turkey is also unsurpassable, when thus grown, by other varieties grown under any other conditions. The fruit must not be gathered till the skin has shrivelled. R. P. B.

PEARS AND APPLES UNDER GLASS.

I BEG to inform Mr. Baines (see page 229) that I grow these fruits to eat; and I can assure him, if he has never had an opportunity of comparing house with open-air ripened apples or pears, he has a treat in store which will shake his allegiance in what, at the present time, he may consider to be "superior fruits." With apples and pears, it is true, I cannot girdle the year with fruit, but I can command a nine months' supply, in great variety and of unsurpassable excellence; and this, more especially for private growers, I consider preferable to a glut of stone fruit at a time when fruit is plentiful. What is it but climate which gives superiority to the pears of France and the Channel Islands? What but climate, backed by cultural skill, renders the pines and grapes of our glass-covered areas superior to those of any other part of the world? Again, compare the superior dessert apples and pears of the south of England with those of the north, and climate again asserts its ascendancy; and, such being the fact, why should we northerners be deprived of glass for our common fruits if we like to indulge in it? A finely-matured peach or bunch of grapes are grand things in the dog days, but perfectly-ripened apples or pears at the present time, when all nature is comparatively asleep, is something equally to be appreciated. These I have learned to regard as superior fruits, necessities which no household ought to be without, while peaches and nectarines may be regarded as luxuries, fruits of a day, which must be used directly they are ripe, or be lost for ever. This is my reason for recommending the house cultivation of apples and pears. What a house-ripened grape is to the same kind from the open wall so is a house-ripened apple, pear, or plum to the same kinds grown in the open air.—W.

SPRING FROSTS IN VINEYARDS.

The *Messager Agricole*, a French periodical devoted to scientific agricultural and horticultural pursuits, publishes a paper on this subject, written by M. Gaston Bazille, président de la Société Centrale d'Agriculture de l'Hérault. "It is," says the author of the memoir, "just before sunrise, when the sky is serene and the atmosphere calm, that danger to the vines is imminent, even when the thermometer is some degrees above the freezing point; but if the heavens are cloudy, or ever so slight a mist obscures the sun, there is no danger to be apprehended. After many trials of various means of producing a dense smoke economically and quickly, and maintaining it from an hour before sunrise until an hour or two after, I have found nothing answer nearly so well as the burning of refuse of coal tar distillation, which costs a mere trifle. This, when set fire to in shallow earthenware pans, gives out a dense black smoke, effectually obscuring the brightest sky. These pans should be placed at intervals of about twenty yards on the east and north sides of the vineyard only; for it is to be observed that it is useless to place them on the south or west, insomuch as when the wind is from these points of the compass the vines never suffer. The critical period appears to be about the middle of April. If," says the memoir, "the sun has set in a clear sky with a north wind, the chances are that there will be frost in the morning, and it is then that my workmen are up earlier than usual. The thermometer is

consulted frequently, and whenever it is found not to be seven degrees above freezing, a number of them, each carrying a lighted torch, pass quickly along the line in which the inflammable material has already been placed in suitable vessels, applying his torch to each as he passes rapidly along, and in a few minutes the whole vineyard is protected by a curtain of black smoke. In the year 1864 this process was repeated on three consecutive days, viz., the 9th, 10th, and 11th of April, at my vineyard of St. Sauveur, and on the first day caused no little alarm to a village situated about five miles south of our operations, and when the cause of the smoke became known created considerable amusement, and gave rise to many jokes by my neighbours at my expense; but, as my vines were preserved while theirs suffered considerably during these three days, they are now, when spring frosts are expected, to be seen in their vineyards torch in hand. The system is not expensive; five or six men will suffice to protect a vineyard of thirty hectares (75 acres), at an outlay of about fifty francs for materials and labour."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Bottling Grapes.—There are some operations connected with horticulture that find favour, more or less, for a time, though their advantages are practically few. Preserving grapes in bottles comes under this denomination. If your grapes are badly grown, deficient alike in finish and flavour, bottle them if you choose; you cannot easily make them worse. But if, on the other hand, they are really good grapes, possessing that first essential, flavour, by all means keep them out of the bottles; for, before they have been in them many weeks, they will be as devoid of flavour as if they had never had any. I have frequently tried the practice, this being invariably the result; and all with whom I have spoken on the subject, who have tried the bottling system, admit that the same thing happens with them—otherwise, it would be a very great convenience to be able to clear a whole crop at once, and so relieve the vines, and be able to use the houses for any other purpose for which they might be required. But this one fact—the destruction of the flavour—is fatal to the practice.—T. BAINES, *Southgate*.

Pruning Old Apple Trees.—I have always supposed that the main object in pruning old trees was to keep up a vigorous, healthy growth; but how can this be done, if all the young and thrifty shoots are annually cut away, and none left but the old and unfeebled heavy branches? This seems to be the general practice, and I am only surprised that these old apple trees live as long as they do. When I want to restore health to an old tree, I cut away as much of the old wood as it seems advisable, and leave that which is young and healthy. One healthy young shoot is worth a dozen old branches for restoring health. After a branch has produced fruit for a dozen or more years, it is sure to show signs of becoming weak; and if the internal structure is examined, the annual deposit of wood will be found very thin. At the same time new shoots will start out of these old branches near their base, are usually termed sap-shoots, and the almost universal practice is to cut them away entirely; but they are sure indications of feebleness in the branches above, and if the trees are very old, a few of them should be encouraged, and the branches above them entirely cut away. Of course, all large wounds made by the removal of such branches should be covered with wax, or some similar composition.—M.

Japan Pear.—This curious-looking fruit has attracted considerable attention from amateur fruit-growers within the past few years,—not so much from the quality of the fruit as from the remarkable growth of wood it makes, and the profusion and size of the leaves. We have specimens in the orchard, grafted a year ago last spring; that made shoots last season ten feet long, and three-quarters of an inch in diameter at the base. The leaves on those shoots are five or six times as large as the ordinary pear leaf. The tree does not shed its leaves until a month or six weeks later than the common pear; and from the 1st September until the 1st of December, the Japan pear makes a beautiful ornamental tree, the foliage becoming equally brilliant as the red maple. We have two varieties, and they are undoubtedly seedlings of the old Chinese Sand pear. James Hogg says, in the December number of the *Agriculturist*, that both of these varieties are quite common in Japan, where the fruit is used for domestic purposes. The fruit of the Japan pear looks more like a russet apple than it does a pear, but the wood and leaf have the characteristics of the pear. One of the varieties is quite fragrant, having a pleasant aroma, not unlike a fine quince. Two years ago last fall, when we fruitied it the first time, we considered the fruit nearly worthless, unless it was to keep and look at all winter. Last fall we had some of these pears put up in the same way as in preserving quinces, and, to our surprise, we find they make very excellent preserves. The tree makes a very rapid growth, bearing early and abundantly. The fruits look like ropes of onions, they are so thick on the branches. With further trial the fruit may prove a substitute for quinces for preserving purposes, and they may be valuable on this account. But even admitting the fruit to be without merit, the Japan pear will make a handsome addition on our grounds as an ornamental tree. The trees of this variety that we have are grafted on the pear, and the union seems quite as good as it does with the common pear, grafted at the same time. Next spring we intend to re-graft the Japan stock with the Seckel and one or two other varieties, to see if the rapid growth of the former will exert any change on the latter, either in wood or fruit.

SOCIETIES, EXHIBITIONS, ETC.

Royal Horticultural Society.—The anniversary meeting of this society took place on Tuesday last. From the report of the council, we learn that the society realised £5,030 from the penny-a-head royalty on visitors to the Exhibition of 1871, who were allowed admission to the garden. It was announced that although in 1870 some loss was sustained at Oxford, last year it was more than redeemed at Nottingham, where the net profit was £744. The sum received this year for annual subscriptions does not materially differ from that of last year; and the number of Fellows continues nearly the same. The sum received for daily admissions and promenades has fallen off from £463 to £172, a deficiency directly traceable, it is said, to the International Exhibition of last year. One step in the right direction is the appointment of a Botanical Professor, who, by lectures, answers to personal inquiries, and other means, shall assist in establishing a more correct knowledge of the principles of botany and horticulture, and of the names of plants, among those of the Fellows and their gardeners who are desirous to profit by the opportunity. Mr. Thistleton Dyer, late Professor of Botany in the University of Dublin, has undertaken the duties of this department, which we doubt not will be efficiently carried out. With respect to Chiswick, although the whole of the open space appropriated to the fruit department has been completed, the new boundary walls have yet to be furnished. Steps, we understand, are now in progress to obtain such trees as are adapted for that purpose, and ere spring has much advanced as complete a collection of Apricots, Cherries, Peaches, and Nectarines as it is possible to obtain shall have been secured, and the former high reputation of the Chiswick Garden for its pomological collections will have been restored. Up to the present time there exist, under the successful re-arrangement of these, about 400 sorts of Apples, 350 of Pears, 300 of Plums, 430 of Cherries, 220 of Vines, and 100 of Figs. Of the last there are yet many varieties that have not been determined. This season arrangements have been made for a trial of Peas, of which the varieties have become so numerous, and the confusion of names so complicated, since the last great trial in the garden. In the Great Vinery there is a very marked improvement in the condition of the Vines since the enlargement and re-dressing of the border, and the heading down of some of the varieties. The new Grape, Madresfield Court, which was at first supposed to be a variety requiring hot treatment, has proved to be one of the very best for a cool house, equaling if not surpassing the Black Hamburg in the high condition it attains under such circumstances. A vine of this variety was planted in company with one of the Black Hamburg in the Rev. Mr. Fountain's viney which was erected in the garden, and although the house has no provision of any kind for being artificially heated, the Madresfield Court grape ripened thoroughly, and was considered to be much better adapted for such a situation than the Black Hamburg. But little opportunity was afforded last season for carrying on the usual trials of flowers, but in the vicinity of the Council Room a new series of beds for the growth of trial plants has been made, and though it was late in the season before these beds were completed, a collection of Bedding Pelargoniums was nevertheless got together, and planted out in time to make satisfactory progress. These were examined in August, when the following awards were made:—First-class Certificates, as Flowering Plants, Lawrence Hoywood, Charley Casbon, Mrs. Mellows, Lady Kirkland, Stanstead Rival, R. Bowley, Waltham Seedling, Louis Veillot, and Penelope. As Foliage Plants, Goldfiner, Macbeth, Louise Smith, and Black Douglas. It is proposed to continue the trials of Bedding Pelargoniums, and to add in the outdoor department collections of Pentstemons and Phloxes, and in the indoor department Fuchsias. On the wall bounding the trial ground on the west, it is proposed to grow examples of ornamental hardy climbers, instead of fruit trees as heretofore. Notwithstanding the reduction of space in the garden, the collection of herbaceous perennials which had been recently acquired, has been retained. H.R. Prince Arthur, Arthur Grote, Esq., F.L.S., and Andrew Murray, Esq., F.L.S., were elected members of the council for the ensuing year; and his Grace the Duke of Buccleuch, K.G., John Clutton, Esq., and Major-General Scott, C.B., were respectively re-elected president, treasurer, and secretary.

Fruit and Floral Meeting, Feb. 14.—The principal features of this meeting were the Orchids, Primulas, and Cyclamens, but here were a good many other subjects of interest. Amongst the Orchids were some noble specimens of *Ceclogyne cristata*, shown by Messrs. Veitch and Williams. Amongst the finest Dendrobiums were a very sweet smelling kind; D. *wardianum*, with a

first class certificate for a magnificent plant of *Laelia anceps*, with nineteen good flower spikes, and measuring about three feet in diameter. Lycastes were numerous and very beautiful, as were the Odontoglossums, and some plants of *Phalaenopsis amabilis* and Schilleriana were nicely bloomed. Vandas, Angraecums, and Cattleyas were well grown and flowered, especially the latter. But the most admired Orchid of the day was *Masdevallia ignea*, which is truly a brilliant acquisition to our cool houses, as it is of easy culture, dwarf, very distinct, and a very free blooming plant. It would seem to be as great a gain among Orchids as the gorgeous *Anthurium Scherzerianum* was among Arums. A spike of the splendid *Amherstia nobilis* was sent from Chatsworth; on the parent plant at present there are upwards of one hundred spikes of lovely yellow-stained red blossom. Cyclamens were shown in splendid condition by many growers. Every winter and spring show proves more and more the unrivaled merits of these for enlivening our greenhouses during the dullest season. In fact if we are happy enough to discover a few other kinds of plants equally useful for winter and spring decoration, our conservatories will prove as gay in January and February as in June or July. Chinese Pritchards were also to be seen in great variety; they show much improvement of late. Ornamental variegated Kale, shown by Mr. Melville, of Jersey, was nicely coloured, and of apparent value for spring decoration in our flower gardens. *Tillandsia Lindenii* was one of the most striking and beautiful objects in the room, being of good habit and producing handsome flower spikes of a fine and distinct blue. Two baskets of Lilly of the Valley, grown by Mr. Howard, were among the finest we remember to have seen. Among hardy spring flowers the sweet-scented and richly-tinted *Iris reticulata* was as usual the gem. *Bouvardias* were shown as cut flowers in neat little bundles, with the stems buried in moss. The *Bouvardias* are invaluable for cutting, and, if we mistake not, will soon be as indispensable for winter and early spring bouquets in this country as they now are in America. There was a large and freely-bloomed specimen of *Daphne indica rubra*, to which a special certificate was awarded. It was grown by Mr. Johnstone, Uxbridge. Dessert apples and pears were in good condition; the winning apples were Blenheim Orange, Ribston Pippin, King of Pippins; the second prize lot containing, in addition to these, Braddick's Nonpareil, Glou Morcean, Winter Nelis, and Pass Colmar, were in the first dishes of pears; other pears shown were Knight's Monarch, Beurré Rance, Prince Albert, Easter Beurré, and Josephine de Malines.

Royal Botanic Society, Regent's Park.—At a recent meeting of this society, the secretary reported the receipt of another specimen of the "Mangrove Tree," from the West Indies; he believed it to be only the second instance of the importation of this curious plant alive to Europe, although numerous attempts have been made. In both instances the society, and natural history generally, are indebted to the care and exertions of the officers of the Royal Mail Steam-packet Company, and Mr. P. Cameron, of St. Thomas, Jamaica, who gave particular attention to the packing and transit of the "plant case," contrived by the secretary of the society, and sent out for the special purpose.

Manchester Botanical and Horticultural Society.—At the annual meeting of this society, which took place the other day, the Council announced that the working of the past year had resulted in a gross profit of £709. 2s. 9d.; which, after appropriation of the amount necessary to pay interest upon the debts of former years, leaves a net sum of £397. 15s. 8d. available for reduction of the principal. We also learn from the report that the ordinary income of the society has exceeded the expenses by £305. 1ls. 8d., notwithstanding that a considerable expenditure has been necessary in renovations and repairs of various portions of the premises. The financial result of the national horticultural show at Whitsuntide was a balance to the credit of the society of £553. 19s. 10d.

Royal Agricultural and Botanical Society of Ghent.—This society, we understand, intends to hold, in March 1873, its usual quinquennial International Horticultural Exhibition, of which the programme will appear early this year.

New Provincial Horticultural Society.—Through the kindness of Mr. Ingram, of Belvoir Castle, we are enabled to announce that a very promising horticultural society has been formed for Grantham and South Lincolnshire. It is established to promote the true interests of horticulture, and is not to be restricted to the getting up of an annual flower show. It is proposed should the society prosper, to endeavour in various ways to further the views of those who desire to extend the practice of gardening amongst villagers, to take cognisance of the state of village gardening, and to distribute good sorts of fruit-trees amongst deserving people. The interest taken in the matter by all classes is best evinced by the extensive and satisfactory list of subscribers, which enables the committee to offer upwards of £200 in prizes, in this, the first year of the society's existence. It is announced that the first summer exhibition is to take place on the 17th and 18th of July next.

[FEB. 17, 1872.]

THE AMATEURS' REMEMBRANCER.

Flower Garden and Shrubberies.—Prepare beds and borders for summer flowers; and, as soon as herbaceous plants are up, slightly fork up the ground among them. Prune the harder kinds of roses; climbing ones, on poles and buildings, undo, thin, and tie up again; sweep and roll lawns. If not already done, plant out anemones and mannequins; finish pruning ornamental trees and shrubs; dress borders of American plants with decayed leaves, scattering a little soil over them, to keep them in their place. Plants requiring stakes should be attended to, and neatly, though firmly, supported before March winds set in.

Indoor Plant Department.—To plants in borders now beginning to grow give a good soaking of tepid water, temperature 45°, and whenever favourable, admit plenty of air. Acacias, Camellias, and other plants coming into bloom must not suffer from want of water. Plants for successive blooming introduce into the forcing-pit, keeping pelargoniums near the glass, so as to have short-jointed wood. In stoves maintain a temperature of from 55° to 60°, allowing a slight rise by sun heat. Prune and pot Almondas, Dipladenias, Clerodendrons, Stephanotias, Rondelias, &c. Start a few Gloxinias, Gesneras, Achimenes, and Calladiums, especially such as show signs of early growth. Water sparingly until the plants begin to grow, and avoid undue excitement and cold currents of air. To orchids give a night temperature of 55°, and from 60° to 65° during the day; the Mexican house may be 8° or 10° lower; avoid excitement. Water only such as show signs of growth; give no water overhead at present, but sprinkle the floor, walls, and stages with tepid water once or twice a day. Retard the blooming of some of the finer kinds of orchids, by removing them into a cooler house; to those coming into flower give all the light possible, but screen them from sudden or bright gleams of sunshine. Potting materials should now be in readiness under cover.

Pits and Frames.—Bedding plants wintered in vineeries and other houses remove to these, keeping them close for a few days—afterwards, admit air freely; protect from frost, wind, and heavy rains. To scarlet geraniums and fancy pelargoniums give a small shift. Heaths require full ventilation; should mildew appear, dust with sulphur, and they must never suffer from want of water, nor get too much. From carnations clear dead leaves, and stir, and refresh the soil. Ten-week and other stocks, Cobea scandens, Lophospermum, Mairandyas, and other choice plants, sow for early flowering on a gentle hot-bed. Pansies, plant out; Dahlias, start in moderate heat for cuttings. Pots, boxes, soils, &c., must now be got in readiness for sowing, shifting, and for cutting.

Indoor Fruit Department.—Prepare for the general potting of pine-apples; but the more advanced among them should have a shift at once. Use every means to get the roots in a growing and healthy state before potting. Vines started require a moist temperature—those setting a dry one; stop and thin shoots of the more advanced, and keep regularly tied those retained. In thinning the shoots, commence at the upper part of the house, and work downwards, taking care of the leaders. Figs, water freely at the root and overhead; encourage short-jointed firm wood, and pinch at the fourth or fifth joint; temperature at night, from 55° to 60°; by day, from 65° to 70°. Peaches and nectarines set, and remove any shoots not required for succession; syringe frequently, and increase the temperature. Introduce fortnightly, successive strawberries, giving plenty of water to those in active growth; whilst those in flower, and setting fruit, are better kept rather dry than moist; give air carefully and early in the day, keeping the temperature at from 65° to 70°. To cucumbers keep up a brisk, moist temperature of 75° at night, and from 80° to 85° by day; to the beds add fresh linings as often as necessary. Set the blooms, and stop the shoots, so as to prevent superfluous growth; water overhead, as well as at the root, with tepid water; if mildew appears, sprinkle with water, and dust with sulphur. As the roots extend, add two or three inches of fresh soil. Melons sufficiently advanced stop, removing superfluous growths and male blossoms, maintain a ground temperature of 85°, admit air cautiously, avoiding cold draughts, sprinkle frequently with the syringe, and encourage short-jointed vines, by keeping the plants near the glass. Seakale lift for succession, and place in a mild temperature, excluding light. Of Asparagus keep up a succession. Capsicums and chilles, sow in heat; those that have made four or five leaves, repeat, and still keep them in heat. Carrots in frames, if up, thin; look after snails and slugs. Keep up a succession of kidney beans, syringe frequently, and keep them near the glass; top-dress with light rich mould those about to fruit. Lettuces, sow on a slight hot-bed for succession; plant autumn-sown ones on a hot bed, temperature, 55° to 60°. Mustard and cress sow in gentle heat every ten days. Egg plants sown last month pot, and keep in moderate heat. Radishes sow in gentle heat. Mint and sage force in succession. Expose peacock raised in heat gradually, and carefully shelter them from frost or cold winds. Celery sow in gentle heat, using a rich compost; those above ground thin or prick out into pans and boxes. Cauliflower, marjoram, and basil, sow in gentle heat, for planting out. To potatoes in frames give plenty of air, and, in watering, do not wet the foliage.

Hardy Fruit and Kitchen Garden.—Protect early blossoms from spring frosts by means of wide coping boards, as shown in our last number, canvas, fish, or woollen netting, branches of evergreens, &c. Pruning of all kinds finish. Prepare grafting clay. Lichens or moss on fruit-tree stems or branches scrape off. Fork up the ground between cabbage plants, lettuces, spinach, and other crops. Portuguese onions sow on a warm border, and afterwards transplant. Peas and beans sow in

a sheltered situation. To cauliflower under hand-glasses give all the air and light possible, and permit them to receive gentle showers in mild weather; but protect them from frost, cold winds, and heavy rains; prick off young cauliflower plants raised in frames. Sow a small crop of round spinach; sow also, an early crop of stone turnips. Lettuces of former sowings transplant; and make a sowing of leeks. Cherries and fennel may now be sown. Tie both long and turnip-rooted radishes on a warm border, and cover with rough litter till the plants appear. Shallots plant in deeply-worked soil, in drills one foot apart, and six inches between the plants. Tie up and branch endive. Seakale and rhubarb cover with pots, and surround them with as much leaves and litter as will generate a heat of 50° or 60°. Tansy, tarragon, balm, mint, horseradish, burnet, &c., may now be propagated by offsets, or division of the roots.

COVENT GARDEN MARKET. February 17th.

Flowers.—Of these there is now great abundance, and some tastefully got up bouquets, consisting of white Camellias, which are invariably used as centre-pieces; spikes of Orchids; Tea Roses; Maiden Hair Ferns; Cyclamens; Violets; Epiphyllums; Tropeolus; Snowdrops; Pelargoniums; Eustoma; Mignonette; Orchids; Orange Blossoms; &c. Among others flowers we noticed, Fuchsias; Bonariads; Gladioli; Primulas, and *P. dentiflora*; Cyclamens, in fine condition; Ditycia spectabilis; Deutzia gracilis; Spirea japonica; Zonal and fancy Pelargoniums; Cytisus; Camellias; Ghent and other Azaleas; Heaths; Cinerarias; Lilacs; Acacias; Thysanocactus urticans; Callas; Crocuses; Snowdrops; Tulips; Narcissus; Hyacinths; Anemones; Polyanthuses; Aralias; Hepaticas; and Aconites. Amongst sweet-scented flowers were Violets, Tee and China Roses, Mignonette, Lily of the Valley, Orange Blossoms, Sweet Bay, and sweet-scented Orchids.

Prices of Fruit.—Apples, Dessert, 2s. to 4s. per dozen.—Cobs, per 100lbs. 6s. to 6s.—Filberts, per lb. 8d. to 10d.—Grapes, per lb. 5s. to 10s.—Lemons, per 100, 7s. to 10s.—Oranges, per 100, 6s. to 10s.—Pears, per dozen, 3s. to 8s.—Pine-apples, per lb. 6s. to 10s.—Pomegranates, each, 4d. to 8d.

Prices of Vegetables.—Artichokes, green, each, 6d. to 8d.—Asparagus, per 100 lbs. 8s. to 10s.—Beet, per dozen, 1s. to 2s.—Broccoli, purple, per bundle, 10d. to 1s. 3d.—Brussels Sprouts, per half sieve, 2s. 6d. to 3s. 6d.—Cabbages, per dozen, 10d. to 1s. 3d.—Capsicums, per 100, 1s. 6d. to 2s.—Carrots, per bunch, 5d. to 7d.—Cauliflowers, per dozen, 2s. to 6s.—Celery, per bundle, 1s. to 2s.—Chillies, per 100, 1s. 6d. to 2s.—Cucumbers, each, 1s. 6d. to 3s.—French Beans, new, per 100, 3s. to 4s.—Herbs, per bunch, 2d. to 4d.—Horse Radish, per bunch, 3s. to 5s.—Leeks, per bunch, 2d. to 4d.—Lettuces (French), Cabbage, per dozen, 1s. to 2s.; Cos, per dozen, 3s. to 5s.—Mushrooms, per potte, 1s. to 2s. 6d.—Onions, per bunch, 2d. to 4d.—Parsley, per bunch; 2d. to 4d.—Radishes, per bunch, 2d.—Rhubarb, per bundle, Gd. to 1s. 6d.—Salsify, per bundle, 9d. to 1s. 3d.—Scorzonera, per bundle, 9d. to 1s. 3d.—Seakale, per punnet, 1s. to 2s.—Shallots, per lb. 8d.—Spinach, per bushel, 3s. to 4s.—Tomatoes, per small punnet, 3d.—Turnips, per bunch, 3d. to 6d.

A Park for Birmingham.—At the quarterly meeting of the Birmingham Town Council this week, the Mayor read a communication from Mr. Alderman Ryland, containing a proposal from his relation, Miss Ryland, of Barford Hill, Wandsworth, to present to the town a piece of land for the purposes of a public park. The piece of land in question, known as the Cannon Hill estate, consists of about 54 acres, and is situated on a picturesquely acclivity on the south of the town, and about two miles from the Town Hall. In the event of the acceptance of her offer, Miss Ryland is prepared to lay out the land in an ornamental manner, at an expense of about £5,000, and to transfer the fee simple to the Corporation, reserving a right of way through the park to the house which overlooks it. The plans contain provisions for cricket and croquet grounds, a gymnasium, and an artificial lake, and the gift altogether is estimated to represent a value of not less than £30,000. It is scarcely necessary to say that the proposal was accepted by the Council, with warm expressions of gratitude to the munificent donor, in whose honour it is proposed to name the new acquisition "Ryland Park."

New Ride in Hyde Park.—The new road and ride, which has been some months in preparation in Hyde Park, was opened last week. It branches out of Rotten Row opposite Albert Gate, cutting across that part of the park on which the first Great Exhibition stood, and runs alongside the drive to Kensington, where it joins the "Row." The length of drive in Hyde Park is thus now nearly doubled.

Trees on the Thames Embankment.—In reply to Mr. Laurence Peel (see p. 271), who entreats the Commissioners "in mercy" to remove the trees from the Thames Embankment, because "if we live so long we shall hereafter see a long avenue of green foliage, and be left to guess at a river which that foliage hides," permit me to remind him that no beauty is so beautiful as when partly veiled, and that "the something" which is left for the imagination to supply is the truest part of all enjoyment.—*A Lover of Foliage.*

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters, *envelope*, Subscriptions, Advertisements, and other business be addressed to THE PUBLISHER, at the same address.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE SIX OF SPADES.

CHAPTER IV.

I MUST tell you now (how one loves to linger even among the naughtinesses of early youth!) how I essayed to avenge myself upon our Gardener for his artful ambuscade behind those Scarlet Runners. He had, in those days, the finest Peaches in our neighbourhood; and upon the occasion of our giving a grand dinner, at which the Ducal party from the Castle graciously assisted, he had sent in such a dish of them as could not be surpassed in the county. The specimen which crowned the pyramid was enormous ("Monstreuse," though not "*de Douai*"), and was the largest I had ever seen, save one, which my eldest sister had made in wax, and in which, so far as size was concerned, she had considerably exceeded the powers of nature. When our guests had arrived (we saw them go through the hall, we little ones, as we stood in our night-gear upon a distant landing, like tipsy Pecksniffs on a reduced scale), and had seated themselves at the banquet, what do you think I had the audacity to do? I stole down stairs, imperfectly accoutred as I was, and substituted the artificial for the real Peach, secreting the latter in a cupboard of the house-keeper's room, where the dessert was lying in state!*

Two hours later, some of the ladies were brought up "to see the children." They found me, as you will conjecture, particularly fast asleep. I was located in an inner nursery, which seemed to be regarded that night, as a small chamber of horrors, attached to the general exhibition. "Is that the arch-traitor?" I heard Lady Isabel ask; "the villain slumbers soundly! let us kiss the hoary miscreant." And then I heard how successfully my scheme had sped. The pyramid had been placed in the centre of the table, and the big Peach had been admired by all. Papa had been complimented, as though he did the pruning and the nailing, and general management of the wall trees, himself. The Duke had facetiously suggested that it should be taken to a side-table, and carved like a round of beef. Squire Granville prophesied that, when it was touched, there would be such an inundation of juice, as would compel the company to swim for their lives. Finally, the Duchess had been persuaded to divide it with her neighbour, and then the imposture was discovered. It had been such fun! Every one had been amused, and Papa, though he seemed puzzled and annoyed at first, had laughed most heartily of all.

All this was very successful; but it was not the success I had intended. Not a word of blame was spoken of him for whose entire confusion and discomfiture I had laid my malignant plans. I alone was censured, and that most mildly. Taken by Mamma to the Castle in the carriage, and my new clothes, I had expressed my penitence to the Duchess, and had been immediately punished with a large casket of the most delicious bonbons I ever tasted.

Some years afterwards, for the war continued, and "revenge, Timotheus cried," through my boyhood, I made another hostile experiment, which had a completely felicitous issue. Once a month, Mr. Evans, the gardener, brought in his account book, and used to sit in an armchair by the fire in the servant's hall, awaiting his master's leisure. From an interview of this kind, my father returned one winter's evening to the bosom of his family, in a condition of extreme bewilderment. "Evans had behaved in the most extraordinary manner. Evans, the soberest man on the estate, was ostentatiously intoxicated;

could scarcely rise to salute his master, and when he did rise had brought the armchair with him, and worn it behind him in the most ridiculous manner. Had never seen any one so demoralised and red in the face. And, to crown all, the man had put himself into a passion, and murmured something about 'standing it no longer,' had sat down with a crash upon his anything but easy chair. There my father had left him; but the first thing in the morning, he would have an explanation—yes, that he would."

I could have given him a very full explanation that evening if I had liked. I had smeared the dark seat of that wooden chair most liberally with cobbler's wax, and had lined my bird securely on his twig.

My father sent for me next morning, after a conversation with Mr. Evans on the subject of his "*seance fantastique*," and commenced an oration of a severe and admonitory character; but he broke down in his second sentence, laughing till the tears rolled down his cheeks and leaving me master of the entire position, with the exception of the kitchen garden, into which I did not feel inclined to wander for many subsequent weeks.

Then came a period wherein we felt that weariness of quarrelling, which the brilliant but bilious *Duc de la Rochefoucault* has termed "*une lassitude de la guerre*," in which we still maintained a pugnacious posture, but struck no blows—just as you have seen a couple of pullets drawn up in order of battle, and confronting each other *tête-à-tête*, but wholly indisposed to peck. Alas! I disturbed this peaceful armistice with an onslaught of unprecedented ferocity. An undergraduate at Oxford, I began to fall in love, indiscriminately, with every pretty girl I saw; and Venus must have dowerets for her golden hair, and fragrant posies for her soft small hand. For her sweet sake ("*nam fuit ante Helenam*," &c.), I commenced such a series of sanguinary raids on the conservatory, as must have made poor Evans's heart to "bleed" almost as freely as his plants. Leaders and laterals, hard wood and soft—now the top of a pyramidal Azalea, to make the centre of a bouquet, now the first fronds of some delicate and costly Fern, to form its graceful fringe—fine old specimens and "nice young stuff;" flowers and foliage all went down in terrible excision, until the place looked as though it were one of her Majesty Queen Flora's gaols, filled with plants of an abandoned character, and having their hair dressed *à la convict*.

Oh, ladies and gentlemen—Oh, dames and damsels with your pretty gardens, and long scissars of shining steel—Oh, gallant lovers, with your trenchant Wharncliffe blades—Oh, mothers and daughters, knocking over the flower pots as you sweep along in your "trailing garments"—Oh, wide-sleeved dandies, breaking the young shoots as you reach forth recklessly to seize your prey—Oh, belles and beaux, so charming, so amiable, and so profoundly ignorant on the subject of plants! Pause awhile, I beseech you, and stay your ruthless hands, for you know not what fatal mischief you may do. One little snip with those sharp "rose nippers," and you may destroy in a moment the pleasant hopes of a skilful taste, and the just reward of a patient industry. You may ruin the symmetry of a plant for ever; and behold hereafter an unsightly dwarf, when you might have gazed upon a glorious *Life Guardsman*. What should you say, fair lady, were some disagreeable miscreant to intrude upon the privacy of your bright little boudoir, and to extract the tail of your piping bulfinch? And you, my brave gentleman, would your observations be entirely such as your pastor would approve, were you to hear from your groom that some coarse-minded person had paid your stables a visit during the night, and "gone the whole hog" with your hunter's mance?

There is provocation, I must allow, sometimes. There are Spades in the floricultural pack, though not in our company (limited), so mean as to the amount, and so sulky as to the manner of their donations, that their scared employers, dare not, finally, ask for a single petal, and so are led to adopt the facile alternative of freely helping themselves.

But how comes it, the question may arise, that the young Oxonian, of whom we heard just now as at fierce war with gardeners, and as cutting and maiming the plants around him with so much brutal solidity, how comes it that he has suddenly put off the paraphernalia of battle for the

* This incident occurred long before the introduction of the *diner à la Russe*.

peaceful apron of the florist, and changed his sword into a pruning knife?

Of this transformation, the happiest event of my life, I must speak hereafter; appropriately, I think, in a little lecture upon Roses, which I am preparing at the request of "The Six of Spades;" but I must first introduce you to the rest of our brotherhood; and now, if you please, to that quaint, hearty, hard-working, plain-speaking, cheery fellow, Joseph Grundy, head gardener, coachman, &c., &c., to the good old ladies at the Grange.

S. R. H.

(To be continued.)

THE FRUIT GARDEN.

THE PEACH AND NECTARINE.

THESE may truly be said to be the most delicious fruits that ripen in the open air of Britain. They are liable, however, to many diseases, some of which may possibly be ascribed to a certain delicacy of constitution incidental to their eastern origin; consequently certain conditions are absolutely necessary to insure their successful cultivation in this country. A matter of paramount importance is their being worked upon a suitable stock. Various kinds of stocks have been tried; but I believe it is now admitted that the Muscle Plum is the best, more particularly for trees intended to be grown in the open air. The healthy or unhealthy condition of the individual stock, as well as its being of the proper variety, has, I may add, much to do with the future success of the tree.

SOIL, SHELTER, OPEN-AIR STANDARDS, FOR CULTURE.

The next important condition is that of the soil. Both the peach and nectarine are found to require, or, at least, to succeed best in a somewhat deep and moderately calcareous soil, which must be rendered entirely free from anything like stagnant moisture. The only other condition I will mention, is that of shelter—or being placed on the south, south-east, or south-west side of a wall, or protecting medium of some sort; and, without compliance with this and the above-mentioned conditions, I fear that there is little probability of successfully cultivating these delicious fruits in the open air in this country. Some years since, encouraged by the success of dwarf pyramidal pears, plums, cherries, &c., an attempt was made at this place to cultivate peaches and nectarines in a similar fashion, and the venture did certainly, to some extent, succeed. During several favourable seasons really good and well-flavoured peaches and nectarines have been borne by dwarf pyramidal trees, growing in the open quarters of a kitchen garden, which many have witnessed. But altogether, the experience of several years' cultivation of these trees has led me to the conclusion that peaches and nectarines cannot be profitably or satisfactorily grown as standards or pyramids in the open air and climate of East Anglia. As we advance in life, there is a tendency to think and to say that things are different from what they were long ago. I have even heard of an old gentleman who maintained that peaches had not the same flavour as they had when he was young. Some of his friends ventured to hint that the supposed change was possibly as much due to his palate as to the peaches. But, be this as it may, my observations lead me to think that for several years past, in many garden establishments, peaches and nectarines have not succeeded so well on open walls as they did many years ago. This circumstance may, possibly with justice, be ascribed to a series of unfavourable seasons, which place the matter, in a great measure, beyond our control, but which may, in turn, be succeeded by seasons more favourable to outdoor success. Nevertheless, although this should prove to be the case, the price of glass is now so much reduced, and orchard houses having become the fashion of the day, it is, doubtless, to these and to similar structures that we have now to look for our principal supply of these useful and delicious fruits. This is more particularly likely to be the case now when the mania for confining fruit trees in pots is quietly subsiding, as it was not difficult to foresee that it would do. For I must say that I have always failed to discover any real advantage likely to be derived from the

practice of growing fruit trees in that manner; notwithstanding this, however, I am quite aware that excellent fruit has been produced by this method, in proof of which I may state that the Barrington and other varieties of peaches were produced here in abundance last year, averaging more than eight ounces each, from pots about fifteen inches in diameter, and the same may probably be done during the ensuing season. Still I should be sorry to depend upon trees in pots for a general supply of either peaches or any other kinds of fruit.

OPEN WALLS, WIRING.

With respect to the use of garden walls in this country, I think that it will ultimately be found to be more profitable, and also more satisfactory, to devote them to the use of our more hardy fruits—including the finer kinds of pears—and, if possible, to discontinue the practice of driving nails into them. This is certainly a great evil; a necessary one, I admit, where other means of securing the trees to them do not exist. But all garden walls, old as well as new, ought to be properly wired for the purposes of training. Nail-holes, irrespective of disfigurement, offer to the various insect-enemies of fruits, in all stages of development, free and comfortable quarters, of which they are by no means slow to avail themselves, and from which it is difficult to dislodge them. The gardening world has to thank you very much for your able advocacy of the wiring system; some months since I was much pleased to see this being carried out in a most efficient manner, under the direction of Mr. Macarthur, in the splendid new gardens of His Highness the Maharajah Dhuleep Singh, at Elvedon, near Thetford, in Norfolk.

CULTURE UNDER GLASS, SPAN-ROOFED ORCHARD HOUSES.

My experience as to the use of glass for the growth of peaches and nectarines, brings me to the conclusion that, in order to obtain fruit of the best quality, from such trees, in abundance, and with something like certainty, we must revert to, or adhere to some modification of, the old system; that is, to train the trees under, and near to the glass roof of such structures as we devote to their culture, thereby securing the greatest possible amount of solar influence. Here we have two span-roofed orchard houses, each about ninety feet in length, twenty feet wide, and twelve feet high in the centre. Both are devoted principally to the cultivation of peaches and nectarines, but the interior arrangements are different. In one house a line of pyramidal peach and nectarine trees occupies the central bed, reaching to the top of the house. These trees are remarkably handsome and healthy, and generally bear good crops of fair-sized fruit, and of good flavour, but somewhat deficient in colour, and a little late in ripening; the latter circumstance, however, is rather an advantage than otherwise, inasmuch as it extends the peach season to the utmost. In the other house the path is in the centre, and the trees are planted on each side, at a distance of some eighteen inches from the side walls, and within a few inches of a hot water pipe, which, though seldom used, is nevertheless available for the exclusion of frost when desirable. Strong wires are stretched through the house lengthways, at a distance of sixteen inches from the glass, and about one foot apart. The stem of each tree is trained vertically across the wires, towards the apex of the roof; and horizontal branches from the vertical stem of each tree are led along each wire; the result is thus a series of cordonsof peaches and nectarines, under each side of the span roof, extending to the entire length of the house. The shoots produced by these cordonso require pinching two or three times during the growing season; they are carefully spurred or pruned during the winter or early spring, and they have never failed to produce abundance of fruit of the finest quality, richly coloured, and altogether greatly superior to the produce of pyramidal trees occupying the central bed of the other house. Indeed, I have no recollection of having ever gathered finer fruit than is annually produced by these horizontally trained trees.

Culford, Bury St. Edmunds.

P. GREVE.

Moss on Fruit Trees.—Syringing with salt water in winter, is reported to destroy this; and some recommend soda water. The salt water should not, it is said, be stronger than sea water, which contains some three per cent. of salt. The best way would be, perhaps, in the first place, to ascertain the right strength on some one tree of little value.

PROTECTION OF WALL TREES.

THERE are those who do not believe in nor practice any form of protection for their fruit trees. Their conviction is, that, taking an average of seasons, they gather more and better fruit without with it. And it must be admitted that over-protection has proved most mischievous. Unsuitable materials and faulty modes of using them have probably ruined more fruit and fruit trees than they have saved. Besides, a radical danger lurks in all protective expedients. Most of them must almost of necessity leave behind them a legacy of weakness. In proportion to their thickness and consequent ability to keep out the cold, they shut out the light; and often the semi-darkness proves more destructive to vegetation than the most severe cold. Hence, until we reach that high state of protection indicated by "W." (see p. 292), when all our tender fruits shall pass safely through their danger period beneath the shelter of glass, the chief merit of our opaque expedients for the protection of fruit trees must consist in devising a happy mean or compromise between the conflicting forces of light and darkness. We must, to write popularly, keep out as much cold and as little light as possible.

One of the oldest and simplest modes of saving the blossoms is that of protecting copings. The theory, as expressed by gardeners, is that frost falls in straight lines. Run out a coping to sever these lines, and the power of the frost is cut asunder and the trees saved. Practically the results are as stated, and I will not burden this paper with the true theory of the matter. Provided the coping is wide enough and sufficiently thick and impervious, it is a safeguard against frost in calm weather. Of course, winds dash the cold air against the blossoms as waves are dashed against perpendicular rocks, and the blossoms may then be frost-bitten, despite the overhanging coping. Still, these copings often prove canopies of safety, and the illustration already given of those in use at Montreuil (p. 269), shows a capital way of using them in a temporary manner. Here is another method equally simple and effective, as practised at Thourmy and

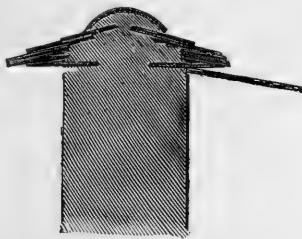

Fig. 1. Permanent and Temporary Copings.

in other parts of France. Modifications of this are also common in England. The illustration pretty clearly explains itself. The wall is surmounted by a heavy, cumbersome coping of tiles projecting about ten inches on either side of it. This is a permanent coping, water and frost proof. But it is not wide enough to shelter the trees. Hence, at intervals of about two yards apart projecting irons, almost twenty inches long, are inserted and slightly inclined towards the earth at the ends. These are the bearers of a secondary coping of wood, bituminized felt frames, or slates. The frames used in France are eighteen inches wide and ten feet long. The felt is simply nailed to light rods of wood, which are easily lifted off and on. These frames being water-proof are much used to protect grapes and other ripe fruits from the autumnal rains, as well as for cold-proof screens early in the spring. Wooden shutters are frequently employed instead of felt. Straw mats, slates, or even a layer of spruce branches, are almost equally serviceable against cold. But, of course, felt or wood are more powerful protectors, inasmuch as they keep the blossoms dry. And, whatever contrariety of opinion prevails about the effect of moist or dry air in moderating or arresting the powers of frost, as a matter of fact, every cultivator knows that a dry blossom-bud passes through a degree of cold unscathed that would have blackened it into death and decomposition had it been wet.

Next in importance to projecting copings follow moveable curtains of textile fabrics, such as canvas, bunting, tiffany, nets of wool, twine, oiled calico, blinds, &c. These are by far the most efficient when kept dry. Therefore, they ought to have the aid of projecting copings, and ready means should be furnished for moving the curtains up or down easily and speedily. This is generally done by means of a roller and pulley, or by suspending the blinds on rings placed on iron rods at top and bottom. Rollers of wood to carry the blinds right off the trees are the best arrangement. With blinds on

rings part of the wall is mostly shaded by the curtains, and the latter are also exposed to all weathers. Not necessarily so, however, for blinds may be drawn up and let down with an arrangement of rings on irons, though not so readily as on rollers. Either way, one great merit of such protectors is their easy portability. They should never be let down at all, unless absolutely wanted. The cultivator scanning the heavens, and sleeping with one eye open, will seldom be caught napping, though occasionally he may have to get out of bed at unseasonable hours to let the blinds down.

Fig. 2 shows a combination of three protectors: a coping of tiles,

Fig. 2. Protected Peach Wall.

another of straw mats, and a third of canvas on rollers. This combination of different methods together ensures the safety of the trees. The canvas is doubled in efficiency by being thus overlapped skywards.

Fig. 3 shows a similar arrangement on a common wall. In this case, however, the canvas is made to overlap two rows of cordon in front of the wall—a capital way of killing three or more birds with one stone; for, indeed, on wide borders five or six rows of cordon fruit trees may be grown. I find the plum does remarkably well as a ground cordon. I am also trying peaches and nectarines. Apples and pears, of course, do well. By growing all our choice fruits near to our walls thus we utilise the heat radiated from their faces, and render it impossible to crop the borders of our fruit trees with vegetables. In a protective point of view we are likewise gainers by inclosing the warm earth at the base of our walls. The earth gives and takes heat more slowly than bricks. Hence, when the walls get cool, the earth helps them; and the more warm earth we can inclose in the same area with our wall trees the better. Of course, the entire border, or only a portion of it, may be inclosed at the option of the cultivator. It will take a little more canvas; but those who have seen or grown most cordons will be the first to declare that it is impossible to do too much for them.

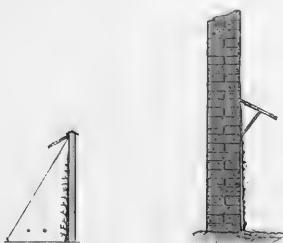

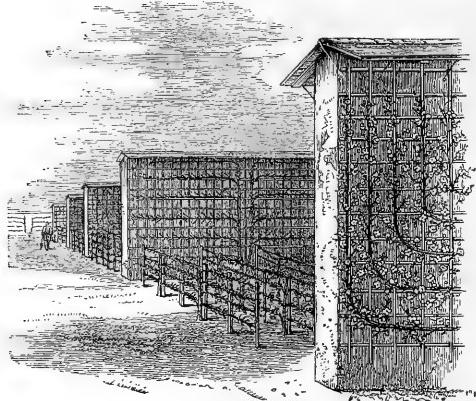

Fig. 3. Protection for Wall and Ground Cordons.

Fig. 4. Coping for Young Peach Trees.

Fig. 4 shows how our means of protection may be brought down to the stature of the trees. Wonderfully simple when seen; but I have noticed many walls with expensive protective expedients all good and proper for mature trees, but useless, because too high above their heads. These simple iron or wooden brackets can rise with the growth of the trees. Of course, as the trees cover more wall, the brackets would be made wider—a point of great importance. For although heat radiates in straight lines, yet the amount of heat returned to the trees on the face of a wall is very much as the breadth of the overhanging coping. Therefore, the higher the wall the wider the coping, if the same efficiency is wanted. In all our various expedients for protecting wall trees, it is singular that so little attention has been paid to the wall itself as a source of warmth. We build walls that our trees may

be warmer on than off them; but we place the walls as far asunder as possible, as if we feared their aggregate warmth would produce a tropical climate. They do not seem to have any such fears in France and Germany. The following is a spring view of a fruit garden in North Germany, on the model of the best of those at Montreuil. The walls run east and west, and are about thirty feet apart. The walls have thus a cumulative effect on the temperature—they give and take from each other, and thus the atmosphere of the fruit garden is sensibly ameliorated. By this "grouping of walls" much shelter may likewise be provided. Cold points and prevailing winds may be built as well as planted out, and special care ought to be taken in the formation of soils, drainage, &c. By choosing a sloping

Fruit Garden in North Germany.—Spring View.

site, or building the walls on a graduated scale from back to front, they might be placed still closer together, say at distances of ten or twelve feet; and the whole space thus be converted into fruit-tree borders. Then curtains or screens, like temporary tents, might be raised over an entire block of walls at once. Indeed, there is no reason why the cultivator should not copy a leaf out of the nurseryman's book in this matter. The latter groups his walls of brick, stone, reed, concrete, wood, or glass, close together for training and growing young trees. This crowding together is chiefly to economise space, but it likewise husband—yes, and accumulates—warmth. Glass walls may be even placed closer to each other, as the light and heat pass freely through; peaches may likewise be grown on both sides to an equal degree of perfection, thus virtually doubling our south wall space. The accumulative effects of the reciprocal action of glass walls upon each other, and their aggregate results on local temperature, promise to be greater than that of any other walls.

From the protection of walls, we advance a step further to the sheltering of espaliers or cordons in open borders. Here is a very simple mode of doing so (Fig. 6), which is now practised in some places.

Fig. 6.

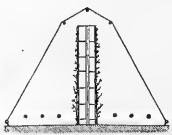

Fig. 7.

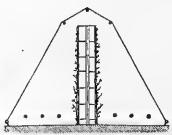

Fig. 8.

Three lines of galvanized wire are carried along the espalier; the centre one rising a foot or so above its top, and the side ones a little under or on a level with the espalier. A few posts will suffice to stretch the wire on; and the width of this triangle may be from three to five feet, according to the height of the espalier. Just before the buds of the trees break, this triangular skeleton should be covered with canvas, bunting, or even common mats. The tighter these are put on, the more rain they will pitch off. Whatever is used can readily be thrown over the wires and made fast by sewing or tying on each side. Figure 7 is a side view of this mode of protection for double lines of espaliers. This simple arrangement is well worthy the attention of every cultivator.

Of late years a sort of prejudice has set in against espaliers, and I confess I prefer nice conical fruit trees to them or any others. But still, when well-managed, espaliers are extremely effective, and may be so treated as to produce a maximum weight of fruit from the smallest area of ground.

Fig. 8 exhibits an extension of a similar mode of protection. In this case the canvas is brought down to the ground, and is made to include three cordons on either side of the double espalier of peers. Of course it would be necessary to roll up or fold back the canvas as far as the triangular roof daily. This would involve a good deal of labour; but it seems not only impolite, but a reckless waste of capital, skill, and time, to allow the fruit crop of a year to be wrecked for lack of this careful protection of the trees for a month or six weeks in the spring.

F.

PEARS AND APPLES UNDER GLASS.

I CAN assure "W." that I have had ample opportunity of comparing these fruits grown under glass with those in the open air. If, regardless of cost in culture, all the attention possible is given them, they are equal to those well done out of doors, but not superior. But it is relatively the same with these fruits under glass, as we generally find it with peaches and nectarines. Those that are under glass receive every attention, whilst those that are outside are comparatively neglected. It is possible that there may be a few kinds that might succeed better inside than out; for instance, the Newtow Pippin Apple is very poor grown in this country, compared with the same sort grown in America; and I have not seen Calville Blanche grown here equal to that kind grown in France. But these are simply the exceptions found in the cultivation of fruits in general. I maintain that the pears grown in France and the Channel Islands are not superior to those grown in this country except in appearance, not in flavour. I can assure "W." that there is nothing extraordinary in keeping up a supply of pears and apples for nine months in the year; with good culture, a judicious selection of sorts, and a well-constructed fruit-room, this can be easily done in any part of the country not absolutely unsuited to the growth of these fruits.

After a dry, warm summer, when I have always found the late-keeping pears and apples to come in much later than in wet, dull summers, I have frequently commenced in July with Citron des Carmes, and ended up in May with *Ne Plus Meuris*.

Anyone has a perfect right to adopt this mode of culture who feels disposed; although it entails three times the amount of cost the productions are worth. But it is opposed to the interests of horticulture to usher this or any other system before the world as possessing advantages which do not belong to it.

Southgate.

T. BAINES.

BOTTLING GRAPES.—I am surprised to find Mr. Baines (p. 292) asserting that bottling grapes deteriorates their flavour. From a rather extensive trial of this system of preserving late grapes, I have not found this to be the case to any great extent where they were thoroughly ripened before being put into the bottles. This I have tried with Lady Downe's Seedling kept in bottles for four successive months, against some left on the vines in the same vineyery, and, if anything, the bottled grapes were the best flavoured when compared. If Mr. Baines can grow late grapes as well as he can cultivate specimen plants, when thoroughly ripe in October or November he may bottle them without any fear of their losing flavour. The great utility of bottling thick-skinned late grapes, such as Trebbiano, Royal Vineyard, Lady Downe's Seedling, and others, is to get the vines pruned and properly dressed every year in season. I used to have grapes hanging in April and May, with the vines in full leaf, and of course this soon had an injurious effect upon the vines. To test their flavour I shall send you a bunch or two of Muscat grapes that have been bottled for three months.—WILLIAM TILLER, *Wesbeck*.

I HAVE forwarded some grapes for your opinion, my employer being anxious to know what you think of them. They have been kept in the grape-room here in bottles of water. The Muscats have been cut from the vines eighteen weeks, and the Lady Downe's Seedling have been cut sixteen weeks from the vines.—RICHARD NISBET, *Asbury Park*.—[We have tasted your grapes, and think their flavor excellent. They have also been submitted to several of our friends, good judges of grapes, all of whom assert that better flavoured Muscats or Lady Downe's have rarely eaten. The bunches, too, are large, the berries plump and sound, and covered with beautiful bloom.]

"NOTES AND QUERIES" repeats an excellent story concerning the Duke of Wellington and the late Mr. Loudon. Mr. John Claudius Loudon wrote to ask the Great Duke for leave to inspect the beeches at Stratfield-say. His writing was not very legible, owing to an affection of his right hand, and it will not appear surprising, therefore, that the then Bishop of London, Dr. J. C. Bloomfield, should have shortly afterwards received the following note:—"My dear Lord,—I shall always be glad to see you at Stratfield-say; and my servant shall show you as many pairs of my breeches as you choose to inspect; but what you want to see them for is quite beyond me.—Yours, &c., WELLINGTON."

ASPECTS OF VEGETATION

TREE FERNS.

SOMETIMES the transition from cold to hot countries is marked by a total change in the character of the vegetation, sometimes by the greater development of the same or similar types. In our latitudes the ferns are lowly and humble—companions of the moss and the short delicate grass or dwarf heather; in warmer latitudes they rear tall and stony columns or stems, from which they throw off crests that rival the palms themselves in stately beauty and grandeur. Their slender trunks rise to the height of from twenty to twenty-eight feet, and from the tops spring large fronds, often eight or nine feet long, bipinnate and feathery, which, from their extraordinary delicacy, are put in tremulous motion by the gentlest wind.

The slender trunks, often quite smooth, and beautifully pitted by the marks of the insertion of the leaves, although they grow to such heights, are sometimes not more than three inches thick. They are confined to the torrid zone; and on some of the East Indian islands they grow in such numbers that their stems are as close to each other as the slender firs and pines are in unthinned plantations. Sometimes the trunks of these tree ferns attain a greater thickness, as much as two feet or more in diameter; but in such instances they are generally cased in a thick layer of roots. Wherever the tree ferns appear within the tropics, from the plain to the height of three thousand or four thousand feet, the soil and atmosphere are full of moisture—indeed, they seem to prefer wet places, and grow in them along with Musaceæ and Scitamineæ. The shrubby ferns prevail rather at the tropics than in the equatorial zone, and they are also less frequent at the foot of tropical mountains than at an elevation between two thousand and three thousand feet. Recent years have witnessed a rich accession of these tropical forms to our gardens. With the hardier palms they constitute the most valuable materials for the picturesque conservatories recently advocated in our columns.

THE KITCHEN GARDEN.

WORTHLESS NOVELTIES.

The adulteration of seeds has often been complained of, but the needless multiplication of varieties is the greater evil. The extent to which this is carried by our seedsmen—even the most respectable of them—could only be justified by real and rapid improvement; and this, we need scarcely say, does not occur. Indeed, some kinds of vegetables are well known to be practically the same now that they were a dozen years ago, and yet our seed houses bring out new varieties every year, and go on christening and selling at a high rate varieties which really have no uncommon merit. Who knows the difference between a slice from Messrs. A. & Co.'s cucumber Emperor of the Longs, sent out at a high price this spring, and some variety in culture for the past ten, twenty, or, it may be, hundred years? Nobody. Yet the gardening public, baited by printed descriptions and new names, are yearly buying varieties of no decided merit, and, it may be, inferior to many good and well-known kinds, for perhaps several times the price of the very best in cultivation. Seedsmen are enabled to carry on this system by the taste that everywhere prevails for novelty. Thus it is that of almost every vegetable there are new and worthless kinds sent out every year, and perhaps the same kind often sent out by different houses under distinct names, to the endless confusion and great injury of the

Aspects of Vegetation.—Tree Ferns.

cultivator. Real and useful novelties are welcomed by everybody; but in the case of our best known vegetables it is rare to find any real improvement, the limits to which they can attain in any one direction seeming to have been detected and fixed in the course of hundreds of generations of their lives. What is sometimes offered as a new pea—the earliest in cultivation—is often simply an old kind under a new name, not a minute earlier than it was twenty-five years ago. The love of novelty, as we have remarked, has a deal to do with this; but it is notable that the same thing does not

prevail on the Continent, where the love of novelty is quite as great as here. We have conversed with a large Parisian seedsmen on the subject, and he regarded it as the greatest evil of the seed trade in this country. "Every one of your seedsmen," said he, "seems to think it necessary to send out a certain number of novelties every year, and we, obliged to buy them to see if they are worth adding to our lists, find as a rule that they are old and worthless kinds, and often that the same kind is sent out by several houses under distinct names." The remedy for this great evil does not seem so clear as that for adulteration. It rests chiefly with the public, who should never invest in new and very dear varieties of the seeds of well-known vegetables, unless they have certain evidence that the said kinds are better than those which they will find marked at less than half the money in the same lists. With flower seeds and seeds of new species it is different, as these, when first breaking into varieties under cultivation, often offer marked interest and value. If a code of nomenclature were fixed on by our Horticultural Society, or some similar body, and the new names and characters only given to kinds possessing real novelty and merit, much good might be done; but the immediate and best remedy remains with the public. They should, as a rule, avoid all new varieties of well-known vegetables, unless in possession of some real proof of their merit; and then they may be spared the disappointment of finding that they have secured a very ordinary or very worthless variety, at, it may be, four times its real value.

PRIZE CELERY.

ORDINARY celery growers commit no greater error in the cultivation of this excellent vegetable than that of sowing it very early and then starving the plants afterwards. As early as the end of January we have seen directions given for sowing the early crop; and the chances are that the plants so raised will be drawn up and stunted into premature old age long before the weather is sufficiently seasonable for them to be transferred to the open trenches. Then follows "bolting," and "kekky" celery, all originating in the check which the plants have received. Plants, to have them crisp and juicy, must be grown with vigour. To sow at the right time, and grow the plants afterwards without a check, is the right way to succeed. This is the secret of the Nottingham system, and in no town is celery generally so well grown. The following is the plan pursued:—About Nottingham celery is grown in almost every garden, and many of the working men grow it with an amount of success only to be attained by those who make its cultivation a hobby, and pursue that hobby with the enthusiasm of men determined to succeed. Among these the late Mr. Samuel Hooley, of Wollaton, was the most successful, so much so as to be justly considered the champion grower of the county. In 1866 he won five first prizes, competing against 129 growers; and in 1867 four first prizes, contesting the pride of place with 126 exhibitors.

CELERY, NATURAL AND CULTIVATED.

Of course, much is achieved by attentive cultivation; but even this, unless you have the proper kind to grow, will not ensure the desired results. When we look to the celery in its original state, choking the ditches in some parts of the country and forming an acrid and dangerous poison, and compare it with the long, thick, solid, and finely formed specimens, perfectly blanched and crisp as an icicle, one cannot but wonder at the ennobling influence of cultivation, and be thankful that the great Giver of all good has blessed us with faculties to convert "weeds" to such useful purposes. Few plants are more esteemed than the celery; for whether stewed or forming part of a salad, it is relished by almost every person. Poisonous when green, it possesses when blanched high medicinal qualities, and is one of the best things which persons suffering from dyspepsia can eat. One of the best kinds of celery is certainly that called Hooley's Conqueror, the kind with which the raiser himself succeeded in conquering all competitors who came against him. It is of the red section, and remarkable for its broad, thick, fleshy leaves, which are almost free from ribs or corrugations. It is the result of careful selection for some years, and at last the character has become so fixed that every plant may

be depended upon as being almost certain to come true to its kind.

PREPARATION OF THE SOIL.

In the cultivation of this plant it is indispensable that the ground be thoroughly drained to the depth of three feet at the least—if four, all the better—and that it be trenched and enriched by the addition of manure and leaf soil to the depth of two feet, mixing the manurial matter as intimately through the soil as possible. The best way to do this will be to trench and ridge the soil at the same time, performing the operation of mixing the dung as the work proceeds. This should be done as early in the autumn as convenient, and during the winter, in dry and frosty weather, the ridges should be frequently forked over so as to expose the whole of the soil as much to the enriching and ameliorating influence of the atmosphere as possible. In this way the whole mass of soil may be brought into fine workable condition. It may seem strange to want well-drained soil for this plant, which is naturally found in ditches and other damp places, but nature is not always the best indicator of the conditions most suitable for a plant in a domesticated state. In a wet soil, Celery grows rank and strong flavoured, and quickly rots when the weather is continuously wet; in a well-drained one, the rain passes speedily away and the soil remains in a healthy condition. In the spring, in March or April, the ground may be levelled down, and then trenches for the plants may be prepared. These should be taken out to the depth of twenty inches and one foot wide, and, if possible, the trenches should run from north to south, so that the sun may act upon both sides alike. Tread the bottom of the trench quite firm, and then place in it perfectly decayed, but rich, horse dung to the depth of eight inches, and that, too, must be trodden pretty firm, then return the soil, and the work is complete, and ready to receive the plants. The trenches should be four feet apart from centre to centre, and the plants must be, when planted, one foot apart. Between the trenches a couple of rows of early potatoes or a row of early peas may be taken, as these will be out of the way by the time the celery requires full exposure. The reason for placing the dung so low is that the roots may get to it, and feed upon it just at the time when the centre leaves, those that will be blanched for exhibition, are pushing up. At that time it will impart increased vigour to the plants, and the leaves will be formed with corresponding strength.

SEED SOWING, AND TREATMENT OF YOUNG PLANTS.

The time for sowing the seed to produce plants for the early autumn exhibition is early in April. At that time a slight bed of hot dung must be made, to receive a small frame, or some hand glasses, and this being covered with some good soil, the seed may be sown very thinly. Shut the frame closely down, and allow it to remain so until the young plants begin to show. Then air must be given daily, and every care must be taken to induce the plants to grow as strongly as possible, and for that purpose, where they come up too thickly, a few of the weaker ones may be drawn out, to give more room for those retained. When the plants have two or three leaves they are in a fit state to plant out in the nursery beds, which must be prepared specially to receive them. The method of preparation is this:—Tread a piece of ground tolerably firm, and upon it place about four inches thick of rotten horse-dung and leaf mould in equal proportions. Tread this firmly, and upon it place about an inch of rich fine soil. Rake this level, water it, and the following day, or as soon as it is dry, it will be fit to receive the plants. These must be put out in lines, the plants being not less than four inches apart, and each plant must be pressed firmly as it is planted. Of course, it is of the greatest importance that the plants be shaded until they recover the transplanting, that they receive copious supplies of manure water when necessary, and that they be kept free from weeds, so as to induce them to grow as robustly as possible. Plants properly cared for will be fit to be removed to the trenches in two months from the time of sowing, say the end of May.

PLANTING IN THE TRENCHES AND SUMMER TREATMENT.

Before planting, each trench must be forked over a full spit deep, and the plants must be put out a foot apart. In

removing them take care to preserve every fibre possible, and this, through the manure being trodden firm, you will be able, to a great extent, to do. Press the soil firm about the roots, water well, and shade the plants from bright sunshine until they are re-established. The summer treatment will consist in thorough cleanliness from weeds, copious watering twice or thrice a week according to the weather, and protection of the plants from being broken by rough winds. For this purpose, it may be necessary, after the plants get a foot high, to tie them loosely with matting, but be careful the ligature does not at any time get tight, so as to cut the plants. In watering, it is essentially necessary that the water be warm at the time it is used, and for this purpose it should either be exposed to the sun in a tub for a day or two before it is used, or it should be taken from a pond. Soft or rain water is the best for all garden purposes, and be careful to give sufficient each time to soak the soil the full depth of the roots. If it can pass freely away by the drainage, you can scarcely give too much water in bright sunny weather, but in dull weather so much will not be required. When the plants are six to nine inches high, weak manure water, prepared by soaking horse-dung and a handful or two of soot in a tub of water, may be given at each alternate watering, and a handful of soot scattered occasionally around the plants upon the ground will be found a valuable stimulant, and will also tend to prevent the ravages of snails and other insect pests. For prize Celery it is not customary to earth the plants much until they receive the final earthing, but a little soil may be scattered over the roots about once a fortnight. This will serve as a mulching, and will encourage the roots to spread on the surface of the soil.

EARTHING AND BLANCHING.

From five to six weeks is the time necessary to ensure the Celery becoming thoroughly blanched, and that is a very essential point in growing it for exhibition. At the time of earthing remove the small leaves from the base of the plants, and at the same time any suckers or secondary shoots that may have formed, cutting or twisting them clean out. This done, fold each plant to the height you intend to carry the soil in clean strong white paper, and tie it loosely with some thin matting, not over strong, as it is necessary it should rot and give way as the plant swells. Some people use tubes, such as drain pipes, around the plants to support the soil, but if tubes are used, the best are those made of iron, zinc, or tin, as they are better conductors than earthenware, and consequently allow the soil to become more quickly warmed or dried in wet weather; the tubes being fixed, fill up to the necessary height with fine light soil, and the work is done. Where tubes are not used the soil must be banked up in the usual manner, taking care to make the bank slope outwards and quite smooth so as to prevent the wet soaking into the centre of the plants. Water must still be copiously applied to the roots, and manure water, weak, but copious in quantity, must be freely administered—the weather, of course, being some guide as to the quantity required.

CELERY FOR EXHIBITION.

Celery about Nottingham, when prepared for show, has only the small outer leaves taken off, and it should be washed quite clean and free from dirt, and be shown in pairs neatly tied together. In addition to the properties before mentioned, viz., the leaves being broad, thick, solid, crisp, and without ridges, they should be free from stringiness and the plants dwarf, sturdy rather than thin and long, and the inner leaves should grow up regularly without spec, stain, or insect blemish. In judging Celery, any plants that are pipy, hollow, or have rotten or discoloured leaves, are at once put aside; and a deformed or run centre is a certain disqualification. The blanching must be perfect and crystal like, and if, in the red kinds, the pink colour does show, it should be of that delicate tint which indicates perfect fitness for table, though not perfect blanching. Add to these qualities fine form and weight, and you have the essentials of a perfect specimen of Celery. In conclusion, we may say the secret of Mr. Hooley's success was, like the secrets of all other successful cultivators—a vigorous plant vigorously pushed forward to its final result. He began late, by which he escaped the risk of the plants starting prematurely to seed, but he lost no time after he did

begin, and hence rarely failed to bring his plants to the head of the prize list on the show day. Of course there is much in the kind grown, but as seed of that and other good kinds is now in the market, that drawback no longer exists. W. P. AYRES.

BROCCOLI.

FIFTY years ago we had good varieties of broccoli, and grew them pretty nearly as well as we do now. We had a good early white, a good late ditto, and an early and late purple, a large brimstone variety, and a sprouting purple. Fashions have changed vastly more than horticulture since those days of knee-breeches and large buckles, when Wellington boots were unknown and Bluchers not discovered. It was about that time when, hearing a good deal of the skill and colossal operations of the London market gardeners—the acres of handlights for early cauliflowers, and the miles of celery—that I started for London, as full of hope, perhaps, as many who went on a higher enterprise. But London generally takes a good deal of the starch out of a young man, poor and without friends, and is usually overawing for awhile till he feels his feet, I remember it was very sleety and stormy in crossing Wimbledon Common, and my spirits were not improved by seeing an old gibbet there, with its chains and irons rattling in the breeze. However, I soon entered a market garden, and felt again at home among the vegetables and flowers that were growing extensively in it for Covent Garden.

At that time people thought as much of their horticultural skill and acuteness as they do now; but I suppose this is true of every generation that has existed since Adam delved and Eve span. At present it is an uncommon thing to hear unthinking though clever people speak as if we had arrived at the climax of horticultural improvement; whereas the truth is there is as much room for investigation and discovery as ever. When we look at the vast surfaces of the earth that have never yet been tickled with a hoe, and consequently never smiled with a harvest—when we think of the comparatively small number of really good fruits that we have succeeded in bringing into popular use; and when we reflect on the multitudes of species found in every clime, and that their uses and capabilities, medicinal or economical, are as yet comparatively unknown, we must own that the ground has hardly been broken yet.

I got on very well in the market gardens, and soon became the manager of the one I entered first. At that time I took every opportunity of seeing good examples of market gardening, independently of the one I was immediately interested in; and I had very little difficulty in doing this, for at that time there were gardens all the way from Pimlico to Putney Bridge, besides those on other sides of London. Ever since that day I have grown quantities of broccoli, and perhaps a few hints from my experience may be of use.

One of the first additions and improvements to the kinds already named was sent out by Messrs. Grange, who kept fruit shops in Piccadilly and Covent Garden, and who had, besides, a large market garden at Hackney. It was called Grange's early white broccoli, and had a great run of popularity, and was then lost sight of, to reappear a few years ago. Something near it in character is Snow's early white—very useful autumn and winter kind, which I have failed to get true from seed of late years. The Malta white is still a good old early spring kind, when we get it true, and its leaves are so arranged as to act as an efficient protection to its head or heart, for the heads are always in close and perfect union in the broccoli tribe. Osborn's dwarf is a delicate and neat little kind, throwing its heart leaves so much open that, if not looked after pretty sharply, every little morning frost disfigures it.

Of all the really useful whites, the Cornish or "large spring white" is my favourite when procured true. By making three or four little sowings of it from the first week in April till the first week in June, and planting these out in succession, fine cauliflower-like broccoli may be cut from Christmas till the following May. This variety has also an advantage in having an abundance of heart leaves to protect it, and is hardy in constitution. It takes a good deal of frost to disfigure it. In fact, I begin to think that, with this and a good variety of cauliflower, we want but little else to keep a supply the whole

year round. It is most likely to be obtained true from Cornwall, as they grow it in quantities there. Of purples, the early Cape is a useful autumn kind. The cooks do not like its colour, though it is tender and of a nice flavour; neither do they like that of the old hardy purple sprouting, which is a useful kind for large consumers. I have left off the culture of most of the purples for years, managing to secure a succession of the best white kinds, which are preferred by all parties. Among other good kinds, I may name Walcheren for the early autumn cuttings, early Penzance, Snow's winter, Knight's protecting, and Somer's particular, and Sulphur and Lake's white for late spring or early summer use.

The object of the country gentleman or private cultivator, as opposed to that of the market gardener, should be a regular succession of good heads, and not a glut at any one time, which might be disposed of by the market gardener, but is often almost thrown away in private gardens. The broccoli is so hardy as to be grown with ease in all parts of the British Isles; but where exposed to the cold blasts it suffers in severe winters, and indeed we have had some winters within the past dozen years that left the broccoli plots a mass of rotten vegetation. It takes a good deal of cold to do that, however, and it even often escapes a scorching frost if a nice coat of snow has fallen previously. Some attempt to protect them by planting them very closely, and by sheltering them with boughs and harder crops, but none of these avail much if it comes to a thorough hard frost. However, as this very rarely happens in Britain, and broccoli as a rule escape, we shall say no more about protection. They are not fastidious about soil, but, like most things; they are partial to good living, and will always be found—like some bipeds—the “best-hearted fellows in the world” when their food and drink are good and in abundance.

Any ground that is cleared off during the season may be planted with them. All garden ground should be sufficiently rich, deeply cultured, and in such tilth that waterings beyond one or two after the first planting, or any other attentions except mere weeding, are unnecessary. From the way in which some talk of using liquid manure, one would think they had quite substituted it for the natural rain. To give liquid manure to broccoli is a thing I never do, nor to any such crop. Well tilled and properly manured garden ground is in no want of liquid manure, and I pity the man who has much to do with it in a tasteful garden.

The first sowing of seed should be in March, the main crop in the end of May, and a little of the Walcheren should be sown in the beginning and end of June. They are, of course, always sown out of doors, but persons wishing to secure a stock for early autumn cutting may facilitate it by sowing a pinch very early in a cold frame, quickly inuring them to the free air and pricking them out on nice warm borders. As a matter of course, the seed should be sown on warm, nicely situated borders, and thinned and pricked out as soon as large enough to handle. They should be planted carefully, using every precaution to keep the roots and leaves as free from injury as possible.

JAMES BARNES.

Two Ways of Travelling.—Going by railroad I do not consider as traveling at all; it is merely “being sent to a place, and very little different from becoming a parcel; the next step to it would of course be telegraphic transport, of which, however, I suppose it has been truly said by Octave Feuillet, “*Il y aurait des gens assez bêtes pour trouver ça amusant.*” If we walk more than ten or twelve miles, it breaks up the day too much; leaving no time for stopping at the stream sides or shady banks, or for any work at the end of the day; besides that the last few miles are apt to be done in a hurry, and may then be considered as lost ground. But if, advancing thus slowly, after some days we approach any more interesting scenery, every yard of the changeful ground becomes precious and quaint; and the continual increase of hope, and of surrounding beauty, affords one of the most exquisite enjoyments possible to the healthy mind; besides that real knowledge is acquired of whatever it is the object of travelling to learn, and a certain sublimity given to all places, so attained, by the true sense of the spaces of earth that separate them. A man who really loves travelling would as soon consent to pack a day of such happiness into an hour of railroad, as one who loved eating would agree, if it were possible, to concentrate his dinner into a pill.—John Ruskin.

THE FLOWER GARDEN.

ROSES AND ROSE CULTURE.

BY S. REYNOLDS HOLE.

Since the accounts of the first National Rose Show were printed in the year 1858, I have not seen in any weekly publication so much interesting information concerning roses as appears in the last number of THE GARDEN.

In the first place, it is to me, and, I doubt not, to many other fond rosarians, a very great gladness to receive from such an authority as Mr. Curtis, of Torquay, not merely the assertion, but the proof, that Devonensis is an English rose. Never until now have I believed that our climate, or rather our miscellaneous collection of climates, could produce such delicate loveliness; and I would urgently exhort our growers of seedling roses and others not to confine their experiments to the hybrid perpetual section, but, remembering Devonensis, to extend their attentions to the family from which she springs. Nor let them hope to evade this duty by pleading that “Devonshire has, of course, THE cream in her Tea.”

In the next place, Mr. Perry's article is a very valuable one. There is not a more reliable judge of roses than he; and he will agree with me, I know, in the statement that, as a rule, the grandest of roses are grown in the budding-ground. But for a beautiful rose garden, for abundant and continuous bloom, for luxuriance of foliage, for endurance of frost—which, if they are mulched can do them no harm—for general effect, and for economy too, his plan of growing roses upon their own roots is by far the best. Vivacious and rampant as the briar is where it is not wanted, it is very shortlived in our rosaries; and it seems often to be a race, generally terminating in a very dead heat, whether the stock or the scion shall expire the first. In Mr. Perry's tasteful and successful garden, where I have seen all that he describes “a blowing and a growing” as only such rose trees can, there is no need of ambulances at every “fall” to bear away the dying and the dead.

And there is no hacking here of the poor Dog-rose, no cruel clipping of his mane and tail (as though he were a French poodle), of which Mr. Baines, at page 276, makes humorous complaint. Heartily do I rejoice to see this prince of plants-men (some day, let us hope, we may be blessed with a Society, not a whit less Royal, but a good deal more Horticultural, than that now dominant, which will delight to honour, by an order of merit, such excellent skill as his) writing about the Rose; and much do I thank him for his welcome, practical hints as to the early treatment of cuttings. His instruction, moreover, is specially opportune, coming in conjunction with Mr. Perry's commendation of roses upon their own roots.

At the same time, I would remind the beginner that it takes three years, as Mr. Perry tells us, to make a rose bush from a cutting; and I would, therefore, advise him to buy at the nurseries. And thus we come to the subject of “Cheap Roses,” also discussed by Mr. Baines, Mr. Fish, and others, in the last number of THE GARDEN. My own conviction is, that, considering the expenses of the grower in rent, wages, glass, and fuel, in the cost of novelties, their uncertain merit and yet more uncertain sale, in grievous losses from drought and damp and frost, the prices charged for rose-trees are perfectly fair and just. And if, simultaneously with his purchase from the growers, the amateur plants briars at seven shillings a hundred, or Mancetti stocks at five shillings, and learns the easy arts of budding and grafting, how else can he fill his garden with beauty at such a moderate outlay?

There is a simpler, shorter, cheaper method of propagating rose trees than any which I have yet seen described, which is known, I dare say, to some of your readers, and which I may shortly, if I am not anticipated, explain to all. At present, having promised to the nurseryman who revealed it to me, to keep his secret, I can only give it to them who ask, What is it? an anecdote in lieu of an answer. Some years ago, one of the minor canons in the Cathedral at Salisbury asked the

prayers of the church at every service for a sick man, whom he mentioned by name. This was done daily, morning and evening, for so long a period that one of the higher dignitaries at last suggested that the name need not be repeated. On which the minor canon, who was very sensitive of interference, gave out at the next service, with an air of injured disgust, "The prayers of the church are desired for an individual whom I'm not at liberty to mention."

For a while I must endure a similar restraint with regard to the multiplication of rose trees.

ENOOTHERA MARGINATA.

This plant is altogether unique amongst its congeners as regards habit and appearance. Commencing at the base, the flowers continue to issue in long succession from the axils of the leaves, and are elevated vertically over remarkably slender tubes, fully a span in length, in a way to produce a beautiful effect. The flowers, as compared with the plant, are of great size, and pure white. The stigma is cruciform and considerably exerted. The description just given, we are quite aware, is very imperfect, and conveys a still more imperfect idea of this fine thing. As yet, so far as we are aware, this *Enothera* is without a specific name. It comes from the State of Utah, North America, and was communicated to Dr. Moore by his friend M. Röezl, of Zurich. When we saw the plant at Glasnevin it promised to seed freely, and we hope ere long to see it widely distributed and taking a prominent position in the choice herbaceous border or cutting a figure in some phase of subtropical gardening, for which its dwarf habit and exotic appearance seem to render it eminently suitable.—*Irish Farmers' Gazette*.—[The plant at Glasnevin is the true *Enothera marginata* (Nuttall), not of *Botanical Mag.*, t. 5,818, which is *Enothera eximia* (A. Gray). The former is much the best plant, producing flowers constantly and daily during four months of summer.]

ACANTHUSES.

These stout and hardy herbaceous plants are of the greatest importance in the picturesque garden or the pleasure-ground, their effect being very good when they are well established. They thrive in almost any soil, but attain their greatest luxuriance and beauty in deep warm ones. The best uses for these species are as isolated tufts in the grass, in the mixed border, or in picturesque groups with other hardy subjects. In all cases they should be placed in positions where they are not likely to be disturbed, as their beauty is not seen until they are well established. All are easily propagated by division. Few herbaceous genera may be made more useful than this. The following are the best kinds:—

ACANTHUS LATIFOLIUS.—The leaves of this are bold and noble in outline, and the plant has a tendency, rare in some hardy things with otherwise fine qualities, to retain them till the end of the season without losing a particle of their freshness and polished verdure. We should not like to advise its being planted in the centre of a flower-bed, or in any other position where it would be disturbed; but in case it were determined to plant permanent groups of fine-leaved hardy plants, then indeed it could be used with great success. Supposing we have an irregular kind of flower-garden or pleasure-ground to deal with (a common case), one of the best things to do with this *Acanthus* is to plant it in the grass, at some distance from the clumps, and perhaps near a few other things of like

character. It is better than any kind of *Acanthus* hitherto commonly cultivated, though one or two of these are fine. Give it deep good soil, and do not grudge it this attention, because, unlike tender plants, it will not give trouble again for a long time.

ACANTHUS LONGIFOLIUS.—A fine, distinct, and new species from Dalmatia and S. Europe, three and a half feet to four feet high, distinguished from *A. mollis* (to which it is allied) by the length and narrowness of its arching leaves. They are about two and a half feet long, very numerous, of a bright green colour, growing at first erect, then inclining and forming a sheaf-like tuft, which has a very fine effect. The flowers are of a wine-red colour, becoming lighter before they fall. A specimen in the gardens of the Museum at Paris, in four years after planting, had twenty-five blooming-stems rising from the midst of a round mass of verdure nearly two and a half feet in height and width. This would be very effective on the undulating and picturesque parts of pleasure-grounds. It does not run so much at the root as *A. mollis*. It seeds more freely than the other kinds, and may be readily increased by seeds as well as by division. Its free-flowering quality makes this species peculiarly valuable, while it is as good as any for isolation or grouping.

ACANTHUS MOLLIS.—A well-known old border-plant from the south of Europe, about three feet high, with leaves nearly two feet long by one foot broad, heart-shaped in outline, and cut into angular toothed lobes. The flowers are white or lilac, the inflorescence forming a remarkable-looking spike, half the length of the stem. Well adapted for borders, isolation, margins of shrubberies, and semi-wild places, in deep ordinary soil, the richer the better. Increased by division of the roots in winter or early spring.

ACANTHUS SPINOSISSIMUS.—This is in all respects among the finest of fine hardy foliage-plants, growing to a height of three and a half feet, and bearing rosy flesh-coloured flowers in spikes of a foot or more in length. It is perfectly hardy, very free in growth, and is quite distinct from any of the other species, forming roundish masses of dark-green leaves, with rather a profusion of glistening spines, by which it is known immediately from its relatives. As a permanent object, fit to plant in a nook in the pleasure-ground or on the turf, associated with the nobler grasses or other plants, there is nothing to surpass it. It does not often flower; and if it should throw up a spike, it will perhaps be no loss to cut it off, as its leaves are its best ornament, though the flowers too are interesting. Never at any time does it require the least attention; it will stand any exposure. It will thrive best in good and deep soil. South of Europe.

Acanthus latifolius (after Vilmorin).

SWEET PEAS.

EVERYBODY admires Sweet Peas for their perfume as well as for their beauty, but few persons grow them so successfully as they could wish; that is, they do not keep them in healthy blooming condition throughout the season. This arises from several causes; first, the ground not being sufficiently rich or deep where they are first planted; secondly, sowing too thick, by which the plants have to battle for life; and thirdly, expecting them to grow in situations where other shrubs or trees are constantly robbing them of their proper supply of nutriment. If the Sweet Pea is to be really well grown, and continue to bloom for many months of the season, the ground or stations must be prepared just the same as you

would prepare them to grow Celery—that is, excavate a trench fifteen or eighteen inches, put in six inches of rotten dung, return the soil, and sow your peas, not in a continuous row, but if a row is to be formed, in patches about a foot apart, placing from six to a dozen Peas in each patch. In this way you will get vigorous development, and, with the assistance of the dung and free watering in dry weather, a plant that can resist some of the vicissitudes to which plant life is exposed. If you wish the blooming to be continuous, you must not allow a single pea to be formed. As fast as the flowers drop, cut off the flower stems, and if, when you are gathering flowers, you cut off some of the points of the branches at the same time you will promote the blooming principle by causing the plants to break afresh and form fresh branches. The purpose and end of all plants is to produce fruit and seed, and we know among annuals, of which the Sweet Pea is one, that so soon as the seed is formed the future energy of the plant is directed to its maturation, and very few fresh flowers are produced. Prevent the formation of seed and the plant will continue for an indefinite period, sometimes for years. From this the importance of removing seed-pods so fast as they are formed should be apparent to every one. A crop of Sweet Peas sown in March and another about the middle of May should command a succession of flowers up to November. Pea sticks generally are not very sightly objects in a dressed garden, but if you procure a sufficient length of three or four inch mesh galvanized wire netting and support it at the right distance and height by neatly painted stakes you may form most efficient, neat, and durable Pea risers.

P. A. W.

MURAL GARDENING.

THERE may be seen—nigh unto the village of Ollerton, Notts, and within view of those grand old oaks of Birklands, which still remain to remind us of Bold Robin and the great Shire Wood—growing in graceful combination upon the walls of a modest little wayside home, two creepers. These are the Variegated Ivy (*Hedera foliis argenteis*) and the Pyracantha (*Crataegus Pyracantha*). The glowing scarlet berries of the latter contrasting beautifully with the silver foliage of the former, seem to brighten the wayfarer's journey, and to

“Cheer the ungenial day;”

and I commend this conjunction to those readers of THE GARDEN who are interested in mural gardening, and who have, horticulturally speaking, a “wall eye.” Furthermore, I avail myself of this opportunity to suggest to them a still more admirable alliance for the summer months, namely, plants in alternation of Rose Maréchal Niel (or Rose Gloire de Dijon) and of Mr. Jackman's magnificent Clematis, which bears his name. When these hang out their banners of purple and gold upon the outer wall, the effect upon the “wall eye” just referred to is almost overpowering.

S. REYNOLDS HOLE.

PRIMULA ALTAICA.

AMONG the choicest gems of the hardy spring garden there are few that will bear comparison with the Altai Primrose (*P. altaica*), and yet I know of few gardens where it is to be found. It was sent to me some years ago as a most interesting and desirable plant, and I have ever since cultivated it with the utmost care. It is, however, delicate in constitution, and I can seldom reckon upon keeping more than two or three robust plants. I suspect it misses the protection of the winter snows of its native home. In general appearance it very closely resembles our own *P. acaulis* (*vulgaris*), but may at once be distinguished by its narrow and more deeply-cleft petals, the reddish hue of its flower stalk, and its singularly attenuated, deeply channelled, and sharply cuspidated calyx, the basis of which is not nearly so deflexed as in *P. acaulis*. The tube of the corolla, too, rises higher above the calyx than in the last named species. The flowers, which are produced in great profusion—quite smothering the plant when it is in a healthy state—are of the most lovely soft mauve, the base sulphur, with an orange spot in the centre. It comes into bloom several weeks earlier than the common Primrose, in fact, it is the companion of the earliest Aconites, Snowdrops, and Snowflakes. It seems to come quite true from seed, but is very shy in ripening any. It ought to be one of the favoured pets of every garden, and I hope some day it may be. It cannot but be loved at first sight wherever it is seen.

The Rectory, Drayton-Beauchamp, Tring. H. HARPER CREWE.

[Along with this communication came a beautiful bloom of this charming Primrose, which is certainly one of the handsomest of the fine genus to which it belongs. In 1819 a plant of it in a pot was exhibited in beautiful condition by Mr. Darbyshire, who found it in a meadow on the Asiatic side of the Bosphorus, near the entrance to the Black Sea.]

SPRING HAS COME.

The sunbeams, lost for half a year,
Slant through my pane the morning rays;
For dry Northwester, cold and clear,
The East blows in its thin blue haze.

At first the snowdrop's bells are seen,
Then close against the sheltering wall
The tulip's horn of dusky green,
The peony's dark unfolding ball.

The golden-chaliced crocus burns;
The long narcissus-blades appear;
The cone-beaked hyacinth returns,
And lights her blue-flamed chandelier.

The willow's whistling lashes, wrung
By the wild winds of gusty March,
With sallow leaflets lightly strung,
Are swaying by the tufted larch.

The clins have robed their slender spray
With full-blown flower and embryo leaf;
Wide o'er the clasping arch of day
Scars like a cloud their hoary chief.

See the proud tulip's flaunting cup,
That flames in glory for an hour—
Behold it withering—then look up—
How meek the forest-monarch's flower!

When wake the violets, Winter dies;
When sprout the elm-buds, Spring is near;
When lilac blossom, Summer cries,
“Bud, little roses! Spring is here!”

The windows blush with fresh bouquets,
Cut with the May-dew on their lips;
The radish all its bloom displays,
Pink as Aurora's finger tips.

Oh, for one spot of living green—
One little spot where leaves can grow—
To love unblamed, to walk unseen,
To dream above, to sleep below!

—Oliver Wendell Holmes.

EARLY FLOWERS.

The following are the earliest and latest dates at which the subjoined plants have flowered during the first four months of the year, from 1850 to 1871, as observed in the Royal Botanic Gardens, Edinburgh, by Mr. James McNab, viz. :-

Name.	Earliest Date.	Latest Date.
Adonis vernalis ...	Feb. 18, 1851	Apr. 19, 1855
Eranthis hyemalis ...	Jan. 15, 1851	Mar. 2, 1855
Heptacodium trilobatum ...	Jan. 14, 1853	Mar. 7, 1855
Draba sibirica ...	Mar. 4, 1852	Apr. 11, 1855
Oreaster vernalis ...	Feb. 25, 1850	Mar. 25, 1852
Nasturtium officinale ...	Feb. 1, 1850	Mar. 20, 1850
Ribes sanguineum ...	Mar. 1, 1869	Apr. 19, 1855
Tussilago farfara ...	Jan. 18, 1863	Feb. 14, 1871
Rhododendron alnifolium ...	Jan. 2, 1851	Apr. 6, 1855
“ nobleanum ...	Jan. 16, 1869	Apr. 13, 1855
Jasminum nudiflorum ...	Jan. 21, 1869	Mar. 18, 1870
Oppimphala verna ...	Feb. 2, 1863	Apr. 23, 1855
Malva parviflora ...	Jan. 17, 1869	Mar. 17, 1870
Scopolia carniolica ...	Feb. 19, 1869	Apr. 9, 1861
Daphne Mezereum ...	Jan. 2, 1851	Apr. 6, 1855
Nordmannia cordifolia ...	Jan. 21, 1869	Apr. 9, 1855
Corylus Avellana ...	Jan. 14, 1855	Mar. 21, 1855
Crocus susianus ...	Jan. 15, 1853	Mar. 8, 1853
“ vernus and var ...	Jan. 18, 1853	Mar. 15, 1853
Sisyrinchium grandiflorum ...	Jan. 14, 1853	Feb. 23, 1870
“ album ...	Feb. 1, 1869	Mar. 19, 1869
Galanthus nivalis ...	Jan. 4, 1858	Mar. 2, 1855
“ plicatus ...	Jan. 26, 1869	Mar. 4, 1870
Leucojum vernum ...	Jan. 17, 1869	Mar. 21, 1853
Narcissus moschatus ...	Mar. 1, 1869	Apr. 13, 1855
“ pseudonarcissus ...	Mar. 23, 1860	Apr. 20, 1855
“ prasinus ...	Mar. 26, 1869	Apr. 2, 1855
Erythronium Dens-canis	Mar. 1, 1851	Apr. 1, 1855
Fritillaria imperialis ...	Mar. 13, 1851	Apr. 14, 1855
Muscari botrysoides ...	Feb. 17, 1853	Apr. 14, 1855
Puschkinia scilloides ...	Feb. 29, 1869	Apr. 16, 1855
Scilla bifolia (blue) ...	Jan. 30, 1866	Apr. 10, 1855
“ (red) ...	Mar. 10, 1863	Apr. 6, 1855
“ (white) ...	Feb. 21, 1863	Apr. 5, 1855
“ major ...	Feb. 21, 1863	Mar. 25, 1870
“ sibirica ...	Feb. 9, 1863	Apr. 21, 1855
Symplocarpus foetidus...	Feb. 4, 1851	Mar. 20, 1855

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Alpine Plants Green in Winter.—I have recently purchased a place with a good deal of raised and rocky bank, within close view of the windows. On these I should like to establish the most interesting kinds of alpine vegetation, especially if I can obtain kinds that do not leave the ground bare in winter. My garden is near a town, but in pure air.—J. F. [The following will suit you well:]

Alyssum montanum	Loiseleuria procumbens	Saxifraga umbrosa
A. saxatile	Lycopodium dendroideum	Selinum acre
Andromeda tetragona	Monotropa uniflora	S. album
Arabis albida	Myosotis sylvatica	Anacampseros
Arenaria balearica	M. sylvatica	S. angustifolia
Aubrieta, in var.	Othonna cheirifolia	S. Eversii
Corydalis lutea	Phlox reptans	S. glauca
Daphne cneorum	P. subulata	S. microcarpae
Dianthus alpinus	Daphne Changibuxus	S. paniculatum
D. neglectus	Primula Auricula	S. sexangulare
Drys Drunamundi	P. integrifolia	Sempervivum calcareum
D. octopetala	Pyrola rotundifolia	S. globiferum
Empetrum nigrum	Sagina glabra, var. corsica	S. Heuffelii
Epicia repens	Saxifraga affinis	S. hirtum
Erica carnea	S. Andrewsii	S. montanum
Erysimum ochroleucum	S. Elandii	S. pectorum
Gaultheria mucronata	S. serpyllifolia	Silene vulgaris
Genista sagittalis	S. cordifolia	S. alpestris
Gentiana acaulis	S. Coccinea	S. Pinnifolia
G. verna	S. crassifolia	Soldanella alpina
Globularia cordifolia	S. Geum	Thymus lanuginosus
Heulinthemum, in var.	S. hirta	Vaccinium Vitis-idea
Hedera, var. petiolaris	S. hyssopoides	Veronica sativata
Leptophyllum buxifolium	S. hyperborea	V. officinalis
Linnaea borealis	S. longifolia	V. minor
Linum arboreum	S. mucosoides	Viola, in var.]
Lithospermum prostratum	S. palmata	
	S. Stanfieldii	

Late Flowering Rhododendrons and Azaleas.—Will some of your correspondents kindly furnish me with the names and colours of a few late flowering good varieties of Rhododendron and hardy Azalea? I am desirous of planting a few first-rate varieties, and prefer late flowering sorts on account of the danger to early ones from spring frosts.—RUSTICS.

The Winter Heliotrope.—This is very suitable for planting by the sides of walks in woods, under trees, or in clay where nothing else will grow. Where other plants of a more objectionable character grow this seems to have the power of exterminating them. It is green the greater part of the year; and at this season, when in flower, its scent is something like that of hawthorn blossom, but not so strong. It must not be introduced into dressed grounds, as it would become a troublesome weed; but by woodland walks and on roadside banks it would never be out of place.—WM. TAYLOR, *Longleat*.

Christmas Roses.—Mr. McNab laid before a recent meeting of the Botanical Society of Edinburgh a variety of Hellebores raised from seed by Mr. G. M. Butler, nurseryman, Finmarch, Greenock, being crosses between Helleborus purpurascens and atro-sanguineus. The habit of the plants, as well as the size of the flowers, approaches H. purpurascens, while the colour is intermediate between the two. These hybrids will prove a great acquisition, as adding to our stock of hardy winter flowering plants, now so much wanted. Mr. Butler does not give any detailed account of their parentage, but it seems evident that the seed has been taken from the H. purpurascens crossed with H. atro-sanguineus.

Cypripedium Calceolus.—Last September I became possessed of a root of this plant, the crown at that time looking as if it would immediately start. I planted it in a forty-eight-sized pot, in coarse turfy peat, kept thoroughly open by a free use of small broken crocks. Up to the present time it has not started at all, and the other day, when I removed some of the soil, to see if it was rooting, I found some of the old roots in a state of decay. I should add that it has been kept near the glass in a house, where the temperature has not been below 45° all the winter. I fear I have treated it wrongly.—S. HILLMAN, *Lower Norwood*.—[C. Calceolus is a perfectly hardy plant, which will grow in the open air in half shady places in any part of Britain. On the fringes of groups of shrubs, in good sand or calcareous loam, it would be likely to thrive, and also on shady banks. A few pieces of calcareous rock broken up with the soil, and also half buried round the plant, are very desirable for it.]

Plants Suitable for a Suburban Public-house.—A correspondent has written to ask an opinion as to the kind of plants most suitable for his front garden, he having recently opened a small suburban tavern. To this, a friend, to whom the query was submitted, has favoured us with the following reply:—“Tell your correspondent he must, in the first place, carefully avoid the *Ten-plant*; and after selecting some respectable plant *in-potter*, he had better purchase a good stout *Ale-plant*. This he must at once make quite tight with strong *Bass*. Should his neighbours make fun of this plant, and call it a *Rum shrub*, he had better remove it, and plant in its stead a *Boose-well-ia*. This, indeed, has some advantages over the former, for its smell is truly *lush-tous*. It, however, requires constant *swilling*. For the border, he might have *Gin-tian* and *Cloves*; these will be found far preferable to either *I-beer-in* or *Mugwort*. Should the boys prove troublesome, and pull up his flowers, he cannot do better than plant a few wild *peeler-goniuns* in the neighbourhood. Our friend “*hops*” this will quite meet the views of the tavern-keeper.—W. G. S.

PUBLIC GARDENS.

THE MANAGEMENT OF OUR PARKS AND PUBLIC GARDENS.

Those interested in selecting trees for planting in positions liable to much smoke could scarcely do better now than stroll into Hyde Park or any other of our London parks and gardens, and observe the aspect of the evergreens as compared with that of the deciduous trees. But nowhere may the ruin be seen more plainly than along the drive in Hyde Park, where it is quite painful to see the filthy and dying objects that were once beautiful and glistening young evergreen conifers. It was simply folly to plant these in this position; as anybody who studies the fate of trees in London could have foretold that they had about as much chance of thriving as if planted in the fire. The whole thing is disgraceful to us as a nation of gardeners; and the worst of it is we do not know who to blame for it. It was done long before Mr. Gibson, than whom no man is more fitted to do justice to the position, was placed in charge of Hyde Park. But even if this were not the case, we could not, if report be correct, blame the superintendent. We understand that our great parks and gardens are not ruled by their appointed guardians, but from the central office. It appears that the functionaries here, not content with selecting the best man they can find for each park or garden, not content with the many important duties which of right belong to them, go further, and are good enough to inform the various able and intelligent superintendents of our public gardens where they are to place their pelargoniums, and, generally, how they are to arrange the details of their charge!

We have reason to believe that this system, so intolerable and unjust to the superintendents of our gardens and parks, and so fraught with evil to the gardens themselves, is applied to the Royal gardens at Kew as well as to the parks. We know of a case in which a superintendent of a park was desirous of getting rid of a peculiarly objectionable feature in one of our most popular parks, and reported accordingly; but orders came not to interfere with it. We assure the reader that nothing in a tea-garden could have been in worse taste, but the answer from Whitehall Place was, “Let it remain!” On the other hand, orders, from which there is no appeal, are given for the execution of the most unwise changes in our gardens. If a mere question of taste were involved in this, we should not have anything to say. Let the reader look at one of the consequences of the system we point out—the hideous “rockwork” at the eastern end of the Serpentine, and he will see at once that it means in at least one case a costly monstrosity in the vilest taste.

Not long ago the site of this was an ordinary steep bank shaded by trees, with an objectionable and watery hollow at its base. It was resolved to improve it by covering it with an extensive “rockwork.” It is difficult to give an idea of what this is like, but numbers of our readers may have an opportunity of seeing it for themselves. Suppose a cottager, in some part of the country where cottagers display grotesque taste in their usually pretty little gardens, to be owner of a few barrowfuls of the rubbish of burnt bricks, clinkers, &c., and to make of these and a little mortar a flat shapeless mass on the ground, with a hole in the middle to act as a sort of vase. Suppose the whole surface of the large bank in the park to be covered with a gigantic and hideous plaster of this kind, and a roundish hole here and there left to be filled with earth for the reception of plants, and the reader who has not an opportunity of seeing this scene will have some idea of what it is. We should hesitate to describe it were it not under the eye of everybody, as people might naturally conceive it incredible that such a course should be pursued in a public park on which vast sums of money are spent.

The “rockwork” once made, then came the planting; and in this, if possible, a greater blunder was committed. Probably the wretched effect of the great bank of plaster and brick-yard rubbish became too evident, and it was resolved to hide it by thick planting; but, in any case, the whole surface is covered with evergreen and often rare shrubs as thickly as the floor of a nurseryman’s wagon on its way to the railway.

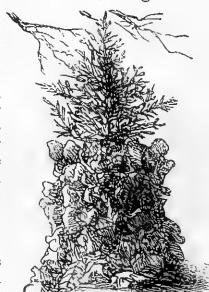

station with a load of specimens. In many cases they are denser than this, and if the reader walks round the fringes of the bank, he will see as many as half-a-dozen choice little shrubs stuck in, and struggling for existence, in one hole, or rather he will see the sickly remnants of them, for of course they gradually perish under such treatment. Delicate and pretty little alpine shrubs, like *Daphne Cneorum*, that always require a little space to spread out and be seen, may be here observed bearing their last few leaves, extinguished under some coarse shrubs; and this in many cases. In one miserable hole here, only large enough to develop a house-leek, or some rock plant with an iron constitution, we observed the following plants:—*Retinospora*, two kinds of *Rhododendron*, an Ivy, a *Genista*, a *Daphne Cneorum*, and a small Cedar.

The whole was done at first just as if it were merely arranged for the sake of its effect for a single evening. It resembled a vast toy garden, planted by children innocent of any notion that the shrubs would grow. Of the judgment used in selecting the subjects, some idea may be formed when it is stated that numbers of plants of the New Zealand Flax were crammed in among the shrubs on the low mounds. But the prime beauty of the planting here has yet to be described. Here and there on the surface of this wonderful "rockwork" may be observed a clinker and cement vase sticking up a couple of feet above its neighbours, and less than two feet in diameter, probably designed to act as the "last great evidences of mountain beauty"; or, say, to afford something of the effect the Lombardy Poplar affords among low-headed trees. What is planted in these pockets elevated in a thin wall of cemented rubbish? A creeper to fall over the sides, or a *Yucca*? No; each contains what was once a promising specimen of one of the noblest and hardest conifers known—the well-known and much-admired *Picea Pinsapo* of Spain, and which forms such imposing forests on the higher and northern parts of the Sierra Nevada. M. Bossier, who discovered this fine tree, which has already formed large specimens both near London and Paris, would indeed be astonished to see it in this position, as would every lover and planter of conifers throughout these islands. In addition to being planted as described, they are placed right under large trees, so that they are in dense shade in summer.

We are, in simple pursuance of our duties, obliged to call attention to eyesores in our public parks; but so long as the system we have alluded to exists, it would be most unfair to blame the superintendents of the gardens or parks, who are not guilty of perpetuating such absurdities as we allude to, and who are powerless to remove them.

The question we now bring up, let no man suppose to be a trifling matter. Let anybody, with a knowledge of trees or general gardening, walk round the "rockwork" alluded to at the end of the Serpentine, and look closely into its structure and planting, noting also the *Piceas* dying in the ridiculous vases just named, and he can only come to one conclusion—that the whole thing is a standing insult to the intelligence of our gardeners and garden architects. We shall continue, then, to point out blemishes of this kind, assuming that the superintendents of our gardens are not responsible for them—at least till we learn that their hands are loosened.

The Cow Tree.—On the parched side of a rock on the mountains of Venezuela grows a tree with dry and leathery foliage, its large woody roots scarcely penetrating into the ground. For several months in the year its leaves are not moistened by a shower; its branches look as if they were dead and withered; but when the trunk is bored, a bland and nourishing milk flows from it. It is at sunrise that the vegetable fountain flows most freely. At that time the natives are seen coming from all parts, provided with large bowls to receive the milk, which grows yellow and thickens at its surface. Some empty their vessels on the spot, while others carry them to their children.—*Humboldt.*

Picea Pinsapo, as planted at the end of the Serpentine (from a sketch in the Field).

A NOBLE NATIONAL PARK.

THE YOSEMITE VALLEY.

N order to form some idea of the noble national park about to be described, let us imagine a noble chain of giant mountains, with towering peaks for months white with snow, with flanks clothed in gigantic forests and rivers with chasms, down which streams are precipitated from vast heights into park-like valleys, forming cascades of astonishing beauty and grandeur, and again dashing onward in "arroyo" torrents through the valley. Let it be imagined further that a region has been discovered, in which the grandest features of alpine scenery are concentrated within comparatively limited space around a valley of surpassing beauty, and then some idea may be formed of the territory which the State Government of California has declared a national park, to be preserved in all its original magnificence as a pleasure ground of the American people for ever.

It is in acts of this kind that the far-seeing sagacity of American rule is exhibited under its most favourable aspect, and in a way that makes its shortcomings in many other directions seem small failings in comparison with its grand sympathies for the well-being of its rapidly increasing millions. In many of the States of the great Federation, stretches of noble scenery have been secured for public parks by timely foresight, before the disfiguring hand of man could settle his tall black chimneys and his noisy workshops like unsightly blotsches on the fair face of beautiful nature. Some of the noble parks thus secured have been briefly described in the pages of THE GARDEN; but those alluded to, though containing grand natural features of rock, of river, of remnants of natural forest, cannot for a moment be compared with the Yosemite Valley, which was proclaimed a people's park in 1865-66.

The Yosemite Valley became known to Europeans for the first time in the year 1850. During the whole time of the Spanish occupation of the country and that of the Americans, till that date the extraordinary beauty of that magnificent recess among the great mountains of the Sierra were utterly unknown except to the Red Indian. In the year 1851, a small mining population of Whites, living on the streams which head round the vicinity of the Yosemite land, found themselves unable to live in peace with the scattered Indians of the region, and a war ensued, in the course of which it was ascertained that the Indians had a secret stronghold high up among the mountains, into which they disappeared whenever they found themselves completely overmatched. In 1851 an expedition was organized to discover this retreat if possible, and drive the Indians from their fastness, which was effected through the treachery of a chief named Tenaya, who led the Whites by the secret tracks of his tribe into the Yosemite Valley. The Indians were terribly disheartened by this betrayal of their retreat, and, after a feeble resistance, made peace, and retired far into the Nevada, leaving the beautiful valley in the undisputed possession of the white man; the Indians who remained being finally expelled after a quarrel in 1852. It was ascertained that in this favourite retreat of the Indians they had a special name for every meadow, every stream, every cliff, and every waterfall in the valley, some of which were picturesquely descriptive, as are so often their own personal names. The waterfall, now known as the Bridal Veil, they called "Po'homō," meaning a blast of wind, and expressive of waving motion imparted by the wind to the slender stream in its fall of nearly a thousand feet. The beautiful cascade now known as the Vernal Fall, they called "Peiuayac," or white water, which is, in fact, but a shower of snowy spray. These are, however, already superseded by English names, many of which, if not always appropriate, are not without their poetry, and will serve to perpetuate the enthusiastic feelings of admiration with which Europeans first beheld the wondrous scenery of this unrivalled alpine valley. That such a spot should have remained undiscovered till within the last twenty-five years appears somewhat extraordinary.

Approaching this "State Park" from the Mariposa side,

SCENE IN A NOBLE NATIONAL PARK.—THE YOSEMITE VALLEY.

near which station was discovered the grove of Giant Wellingtonias, which has also been declared national property, the visitor arrives at an opening in a great ledge of rock, about seven thousand feet above the sea level, from which the first view into the valley is obtained. It has been named "Inspiration Point." The entire valley is about six miles in length, and from half a mile to a mile in breadth, and sunk almost a mile (perpendicular) below the general level of the adjacent region. It may be roughly likened, as has been said by an American describer, to "a gigantic trough, hollowed out in the mountains nearly at right angles to their regular bend. The vast chasm is, however, of extremely irregular form, being characterised by prominently jutting angles and deep recesses; its stupendous walls, which are, on an average, above two thousand feet high, being as nearly perpendicular as can be well conceived in alpine scenery—one deep sheer cut down, productive of the most startling effect when seen for the first time. Its detached features are so remarkable, that any one of its great domes of granite—any one of its great waterfalls—would be sufficient in Europe to attract travellers from all parts.

From Inspiration Point to the bottom of the valley is a deep descent of nearly three thousand feet. The more striking features which first present themselves are, on the left, the enormous rock called "El Capitano," which one cannot help thinking may have been so named by one of those Spanish friars who are known to have penetrated far into the mountains in their missionary pursuits. At all events, the name is an appropriate one. It is, indeed, the Captain rock, standing at the head of all its giant congeners—the true *hetman*, as a Cossack might say, of the granite giants that wall in the valley.

Another great rock, with rounded and polished crest, which seems to have been half cut away from base to summit, is conspicuously visible over the Sentinel Rock, and is known as the "Half Dome." Opposite El Capitano is the gracefully-beautiful waterfall known as the Bridal Veil, which precipitates itself, in its first clear leap, to a depth of 630 feet, when it strikes on a projecting ledge, and makes another plunge of 300 feet, the total height being over 900 feet. As seen at a distance, it seems sometimes to flutter like a white lace veil, producing an indescribably beautiful and peculiar effect, from which it has received its poetical name.

On the other side of the valley is a cascade nearly, if not quite, as beautiful, which has received the name of "Virgin's Tears," which again suggests the visit of some pious Spanish friar, as the modern mining population of Anglo-Americans would be hardly likely to have conferred a name founded upon Roman Catholic legends. This fall makes a clear descent of more than a thousand feet into a deep recess of rocks; and in the spring, when the supply of water is abundant, forms an exquisitely beautiful object. Yet this cascade, very superior to the celebrated Staubbach of the Swiss Valley of Lauterbrunnen, is hardly spoken of as remarkable among the marvellous beauties of the Yosemite Valley. The towering group of rocks called the Cathedral, from their turreted aspect, rise 2,660 feet above the base of the valley, and yet are far less lofty, less massive, and less impressive, than El Capitano.

The next object that attracts attention is a detached rock call the Obelisk, or Sentinel Rock, from the foot of which the first glimpse is obtained of the grandest of all the grand features of this marvellous valley, the Yosemite Fall itself, which, taking into consideration its height and its surroundings, may, perhaps, be considered the grandest and most picturesque cascade in the world—so many elements of beauty and grandeur are combined in this grand fall and its accessories. Its vertical height, it is assumed, surpasses that of any known waterfall in the world. In the central depths of the Himalayas or Andes there may lurk concealed some miraculously-formed valley, whose features, both in rock and water, may surpass those of the Yosemite, but such regions have not yet been discovered; therefore, the Yosemite Fall, of its kind, remains at present supreme. In the spring, when the snows first begin to melt, the volume of water of the Yosemite Fall is very great. At its average, the breadth of the stream which falls over the lofty granite ledge is about twenty feet; but, in the early spring the supply of water is nearly treble what it becomes at a late period. The first vertical descent of

this cascade exceeds 1,500 feet. From the ledge on which it strikes, it makes a further descent of 600 feet in a series of plunging falls, and then takes a final leap of 400 feet on to a talus of low rock at the base of the precipice. As the various portions of the fall are upon one vertical plane, the effect is fully as grand, and even more picturesque than it would be if the descent were made in a single leap from the summit to the bottom of the valley, a depth of 2,500 feet! The descending mass of water is too great to allow of its being broken up into spray; nevertheless, it widens considerably in the course of the descent, and at the base, at high-water time, its general width is not much less than 300 feet. At a moderate state of water supply, it has been estimated the quantity projected over the summit is at the rate of 220 cubic feet per second.

One of the principal characteristics of the Yosemite Valley is the close concentration of so many magnificent features, the great fall, for instance, being only distant in a straight line from the Sentinel Dome two and a half miles, and the extraordinary clearness of the atmosphere makes it appear less than half that distance. In springtime, and at the period of full moon, the scenery of this valley is perfectly magical, and no description—not even that of a Byron, if such a genius were again available—could ever approach in words, the glorious majesty of the scene. We know well how he could paint alpine scenery by what he said when he makes Manfred exclaim, as he issues from his mountain laboratory at night, and paints the Alps by moonlight,—

"The stars are forth, the moon above the tops
Of the snow-shining mountains.—Beautiful!"

And, again, in words that might apply to the rent rocks and tumbling waters of the Yosemite Vale, lit by the moon,—

"And thou diest shine, thou rolling moon, upon
All this, and cast a wide and tender light,
Which softened down the hoar austerity
Of rugged desolation."

But even touches like these of an inspired pen would paint but vaguely the marvellous and endless details of exquisite beauty, which shines out in the soft spectral light of the California moon, in early springtime.

A remarkable cliff beyond the Yosemite Falls rises to the height of 3,030 feet above the level of the valley, and a little further on an Indian canyon may be ascended by good climbers, from which a magnificent view of the whole region may be obtained. Many more such features, combined with the aspect of the waters of the Merced, which run through the valley, and the beauty of the Californian flowers that cluster about the roots of the noble detached trees, and carpet, in the season, the open spaces in the denser woods and the alpine meadows during spring and summer, render this region of concentrated natural beauty and grandeur, one of the most remarkable spots on earth. What a chance America has of making its vast inheritance the noblest and most attractive in the world! Scenes of matchless magnificence lie spread out before her, unencumbered by any of the claims of private property, and that can by a stroke of the official pen, be made public property for the enjoyment of all, as a common possession. In our thickly populated country there is no longer a chance of securing such national privileges without an entire remanipulation of our land system. There was once a time—only then public parks were not dreamt of—when we might have enclosed many a noble piece of land, which might have formed natural parks of great beauty.

But the times for doing so are long past with us, and it is only by struggles with already established "rights" that we can now receive a few shreds of land, here and there, for popular purposes. The remaining scrap of Hampstead Heath had to be purchased from the Lord of the Manor with a large sum of money taken from the taxation of the whole people. The remnant of our once grand Essex forest has to be fought for foot by foot, or dearly paid for. The claim for a little extension of Victoria Park, in order to afford a little more breathing space for the dense population of eastern London, is deemed an unwarrantable demand by our tight-handed Chancellor of the Exchequer; and, in short, the time is past with us for doing that which the State Legislature of California has effected with such far-seeing wisdom. NOEL HUMPHREYS.

THE BOTANIC GARDEN AT GLASNEVIN. (FROM DR. MOORE'S REPORT.)

In the Palm-house, two of the large palms have flowered and perfected their seeds, from which young crops have been raised. One, *Seaforthia elegans*, a feather-leaved species, native of Australia, is now nearly forty feet high; the other, *Lataenia borbonica*, a fan-leaved kind, from the Isle de Bourbon, has attained nearly the same height as the former. In one of the other warm conservatories the Mango tree, *Mangifera indica*, bore ripe fruit last year. The chocolate tree, *Theobroma cacao*, is also fruiting again. The flaming ferns are growing well in the house lately erected for their culture. The different species of *Trichomanes* and *Hymenophyllum* seem quite at home in it, and have been much admired by many of the visitors who have seen them. The fine collection of tree ferns which is now in this garden continues to make progress; but it is difficult to make an atmosphere exactly suitable for them in ordinary conservatories where they are associated with other kinds of plants. Additions of considerable interest have been made to all the departments in the garden, in the way of plants, which have been obtained partly by purchase, but mostly by exchange. The journey I made to the principal botanical establishments in Belgium, Switzerland, and Germany, during the month of July last, enabled me to make selections from them of such plants as were much required at Glasnevin, and to supply in return those selected by the directors of botanical gardens, &c., from our lists. By no other means can a good botanical collection be properly maintained, where it is necessary to grow many kinds of plants not to be found in commerce. The gardens have been much frequented during the past session by the professors of botany and their students, belonging to several of the medical schools in Dublin, for the purpose of teaching and studying from the arranged plants. Notwithstanding the unusually wet summer of last year, a very large number of persons have visited the garden, on both week-days and Sundays. The books show that the Sunday visitors, during the year, amount to 170,170; on week-days, 54,889. Total, 225,059.

Public Park.—On Tuesday, February 6th, the Warrington Town Council passed a resolution, authorizing the purchase, by the town, of Bank Hall and its beautiful grounds for the sum of £50,000, for the purpose of forming a public park. The mansion is to undergo certain alterations and additions, which will fit it for a town hall, to which will be attached suitable handsome buildings for a police station and a fire-engine station. While we find so much difficulty in raising £24,000 to secure a small extension of Victoria Park for the vast population of East London, we are fairly put to shame by the spirit displayed by this provincial town. The cases are not precisely analogous, a park for the population of Warrington being, comparatively speaking, a luxury, and, therefore, more properly be paid for by themselves. But, had not the means been forthcoming, as they evidently are, it would have been incumbent upon the Government to come to the aid of Warrington, in a case where the health and wholesome recreation of the people are concerned.

Meetings in the Parks.—Mr. Ayrton's Bill for the regulation of the Royal Parks and Gardens contains the following among the eighteen regulations to be enacted by the Bill:—"No person shall deliver, or invite any person to deliver, any public address in a park except in accordance with the rules of the park." The rules (except as to any matter within the jurisdiction of the Ranger) are to be made by the Commissioners of her Majesty's Works and Public Buildings. The Bill applies to Hyde Park, the Green Park, Kensington Gardens, St. James's, Regent's, Victoria, Kennington, Greenwich, Battersea, and Bushy parks, Richmond Park and Green, Hampton Court Park and Green, Kew Gardens, Chelsea Gardens, Parliament Square Gardens, Primrose Hill, HolYROD Park, and Lulilithgow Park.

Proposed New Market near Leicester Square.—The company which has been formed for the erection of a new market close to Leicester Square, near Coventry Street, include in their plans a proposal to build on a portion of the square, dividing it into wide and spacious streets, leaving about half the area of the square open and still unbuilt upon. It is suggested that the site and the property in the locality will be enhanced in value by the opening of a fruit and vegetable market on the side of Coventry Street, with two entrances from the last-named street, and platforms underneath, connected with the new railway which is about to be constructed, so as to unite the Euston with the Charing Cross and Waterloo stations. All the requisite plans in connection with the company's proposed works have been deposited with Parliament.

Hardening Asphalte Covering.—Nothing can be done till summer; then on a hot day, give a coat of coal tar; this will dry in a few days; then boil pitch, tar, and tallow together. I do it by rule of thumb—say, one of tallow and three of pitch to four of tar; put this on a hot day, and, if properly done, roofs or paths will require no further care for years; ten feet square may be tarred with a sweeping-brush in ten minutes.—*English Mechanic*.

A WINTER GARDEN FOR LONDON.

WHAT resources have the people in the way of enjoyment during spring and summer? Let the myriads that throng our public parks and gardens answer. The human frame, pent up in close workshops or rooms for many days together, sighs eagerly for a glimpse of nature, a breath of fresh air, the odours of sweet flowers, the enjoyment of the beautiful, even though to be had only in a London park. To rich and poor alike, our Hyde, Victoria, and Battersea parks, or our Kew and Hampton Court gardens, are glorious institutions, of which, while the sun shines warmly, one never tires. The noble umbraeous trees, the green velvet sward, the orange or scarlet tufted shrubs, and, not least, the beautiful flowers, with the many and varied tints of foliage, planted out in quaint and captivating forms, all combine to allure and attract the attention of all classes. We are proud of our parks, and justly, but these are but fair weather sights; and, when winter comes, where can the poor Londoner enjoy his holiday? My earnest wish, therefore, is that either the Government or private capitalists would establish within our midst a veritable winter garden. But what sort of a garden is practicable? We want our winter garden to be vast in its proportions. Nothing but a large area, enclosed and covered by iron and glass, will suffice. The kind of building in which such a garden should exist must not be a temple dedicated to Flora—a thing to look at only. It is not in height but in breadth that we shall find our hopes realised—a building that shall hold within its bounds the simplest flower or the choicest plant as easily as they can now be cultivated within the bounds of the humblest glass structure our gardens afford is what we want.

Our winter garden ought to be placed in some sheltered spot in a deep crescent of trees and shrubs, which should shield it from the north and east winds, whilst its entire area should be encircled with shrubs and borders. The glass erection should be strong, and consist of a series of half-circular roofs, supported upon neat iron columns, plenty of ventilation being provided, as well as wide and roomy gutters, so as to enable snow and dirt to be cleared off with facility. Within we would have, at least, one small portion divided by a glass partition from the remainder, and which should be devoted to the cultivation of plants and flowers that need heat to have them in perfection. In the larger area, however, there should only be maintained a moderate degree of heat, so that, with proper cultivation, the humble primrose and the violet should blossom as favourably in the vast structure as on the banks of our fields and meadows. We want neither shelves nor stages, but artistically arranged banks, beds, and borders, all margined with *Lycopodium*, succulents, ornamental grasses, and any kinds of vegetation that will thrive well under glass. All through these beds and borders must be planted masses of *Camellias*, *Azaleas*, *Cytisus*, *Coronillas*, and all kinds of winter-flowering plants, whilst hardy ferns, palms, &c., shall tower up and display their splendid forms to the gaze of admiring multitudes. As far as possible, the groundwork of these beds must be covered with all kinds of plants that experience has shown to be useful for winter decoration, not even the humblest hedge flower being forgotten. Running like a network all over the wide area should be broad, smooth gravel or asphalté pathways, over which thousands might wander without discomfort, and be delighted with the charms that so beautiful a spectacle would present. Seats in all kinds of recesses, and at all commanding spots, should be abundantly provided, and nothing should be wanting to make our winter garden the most beautiful, enjoyable, and captivating place of resort that the metropolis could boast through the dull, dead days of winter.

Then we must have miniature waterfalls on rockwork; and, in order that the flowing streams should be at a proper temperature, we would have them previously to entrance subjected to the action of powerful jets of steam, and thus not a little would be accomplished towards the maintenance of an agreeable temperature. Such a winter garden would be a boon to us.

Perhaps much of what I have advised is incapable of realisation, but at least the conception will bear consideration. One thing is certain: our winter garden must be within reach of the people, and not placed eight or nine miles away, making the cost of travelling greater than the cost of admission. Great as have hitherto been our horticultural enterprises, a good winter garden will exceed them all.

A. D.

New Mode of "Watering" Streets.—Some days since, at a meeting of the Paddington Vestry, at which tenders were received for watering, slopping, &c., it was resolved by a large majority to accept Mr. Cooper's tender for "watering" the parish with his patent salts for the ensuing twelve months. We presume these are something of the nature of the deliquescent salts tried in Paris.

GREAT GARDENS OF EUROPE.

VERSAILLES.

THE GARDENS OF THE LITTLE TRIANON.

BY NOEL HUMPHREYS.

The gardens of the Little Trianon never fail to produce an agreeable impression upon the visitor after the grand formalities of the great gardens of the palace. Their comparative simplicity and the refreshing irregularity of the walks and plantations, in professed imitation of nature, are undoubtedly a source of relief to the explorer who has undergone the fatigues of the endless rectangular walks oppressed with the legions of statues, urns, and fountains of the great gardens. Nevertheless, the comparative naturalness of these pretty grounds is not above criticism. The Marquis de Girardin, when he purchased the celebrated domain of Ermenonville in 1762, proceeded to embellish it after his own carefully cultivated taste in the matter of landscape gardening; upon which subject he published a treatise, the title of which may

clear lake in which they are reflected, and turn his attention to the finely-grown trees, many of which first flourished in Europe in the soil of the Trianon, he cannot but feel that the pretty *jardin paysage* is a very pleasant place. Even the somewhat over-classical Temple of Love is so prettily situated on the picturesque island, that one is inclined to give in even to the pretence of its name, and Bouchardon's elegant statuette of Cupid, cutting his bow out of the club of Hercules, is such a graceful fancy, that the imagination is led away captive, and, not troubling itself about shams, is simply delighted with the pretty effect of the little edifice reflected in the lake.

Even the imitation "Swiss Village," fails to offend, and the "natural" arch of foliage at the side of the lakelet, one base of which terminates in the water, is so tastefully and naturally managed that criticism is so fairly led away by it, that the trickiness of the thing evades notice.

There is one feature in the gardens of the Little Trianon—a little building overgrown with ivy and deeply embosomed among noble trees—which is so truly picturesque and attractive that it matters little whether it be a reality or a sham, for it is

Scene in the Gardens of the Little Trianon.

be thus translated, "On the Composition of Landscapes, and the Means of Embellishing Nature." He hastened to put in practice at Ermenonville the theories enunciated in his work; and the result of his labours has been thus described by a clever though somewhat cynical critic:—"This is certainly a return in the direction of nature; but accompanied by the unfortunate determination to ornament it by the introduction of sham ruins, imitation cottages, pretended temples, false tombs, and other devices of a similar class, such as verses inscribed on rocks, or half-obliterated inscriptions on fallen fragments of stone; it being expected that a wanderer among those serpentine paths should feel a vivid pleasure in the deciphering of some sublime phrase half overgrown with moss on the face of a rock, or to fall into a pleasing reverie in the contemplation of the fallen stones of the sham ruin." Absolutely similar remarks might be made on the planning and decorations of the gardens of the Petit Trianon, which have also their sham seigniorial castle, their sham *chaumières*, their imitation mill, and their utterly idle, yet very pretty mill stream. But if the visitor will only shut up his cynical criticism, and admire the green slopes and the

undoubtedly a very charming object; so charming, that few will care to be told that it was originally built as a *real dairy*, which it now only pretends to be, as it is no longer used for that purpose.

In summing up the general merits of the great park and gardens of Versailles, it must be admitted that as a grand geometric garden, supposed to be in accordance with the architecture of the palace, it is the most sumptuous example of its kind that regal expenditure and the labour and genius of a host of great artists ever produced, or that is ever likely to be produced—at any rate in Europe. In such a system of gardening, the beauty of flowers, the contrasts of various kinds of foliage, the grandly contrasted natural forms of trees, and the irregularly and picturesquely sedged edges of sparkling water, perform no part, or, at all events, a very minor part. And therefore, this system of palatial gardening must be judged, to a great extent, according to the principles, good or bad, upon which it is based. We must at the same time concede to the little landscape garden of the Trianon the merit of being sufficiently charming to prevent the most cynical critic from objecting to it.

THE INDOOR GARDEN.

SAND AN UNSUSPECTED PLANT-KILLER.

All is not gold that glitters, we know; and it is equally true, though not so well known, that all is not sand that looks to be so. I have even found in some so-called silver-sands a large percentage of lime. It looked white and sparkling, but tested with water it made a milk-like infusion. Many such-sands contain lime enough to kill whole colonies of heaths or other choice plants. And as to coloured sands, they are still more impure; and the more colour, as a rule, the greater the impurity; for the colour is the stain left by some earth or iron that is certain to be injurious to plants. Reigate silver-sand is the best. The partiality of cultivators for this is well known to dealers in sand; consequently, they all profess to come from Reigate, though many of them get their supplies much nearer where they live. I have even had white sand from the seashore offered for pure Reigate.

The purification of sand for the potting of choico plants is a branch of gardening that has been much neglected. Great care has been exercised in the selection of peats and the choice of loams, and their qualities have been, and are, tested in various ways; but sands have received far less attention; and yet the best sweetened loam and peat may speedily be converted into plant poison by means of impure sands. The best sand I ever had was pounded down from white free or sand stone. A good portion of it was used in a roughish state, and the roots of Heaths, Epacries, Azaleas, &c., clung to these as if they were pearls of great price to them; and the fine sand seemed almost equally esteemed. For the potting of choicer plants, all sands should be passed through fire and water first. The first burns out any organic impurities, and the latter washes out fine earthy matter. Some portions of sand may even be too fine for our purpose, and their minute particles can be washed out. Sand is used chiefly for mechanical reasons; it balks, if I may so express it, the cohesive power of soils, and hinders them from running too closely together. Hence, the grittier it is, in reason, the better. For soft-wooded plants and common purposes, I prefer road to pit sand. Both ought to be washed; and when this is done, the reason of the preference will appear. Take the same quantity of each to start with, and at the end of the washing we will find generally as much again of the road as the pit sand left. Of course the latter varies immensely in quality, and occasionally pits of pretty pure coloured sand are found. But very often pit sands contain fifty or more percent. of coloured earths, soft, fine, useless, and it may be highly injurious.

Sand might readily be burnt in our boiler furnaces in small portable retorts; and were its purification, either by fire or water, more general, we should hear fewer complaints of sour soils that the roots refused to feed upon, and of sudden and apparently unaccountable deaths among choice plants.

D. T. FISKE.

AN OLD PLANT OF THE DWARF FAN PALM.

This is usually seen in such a dwarf condition that few of us would suspect it to attain such stature as that represented by the specimen now figured. It grows, and has long grown, in the Garden of Plants at Paris, where it and a companion plant are placed every year in the open air. This Palm, valuable in all stages, is particularly so for narrow corridors, glass-covered passages, &c., where a tall, graceful, and tropical type of vegetation is required, and where there is no room for wide-spreading forms.

CONSERVATORIES IN THE NATURAL STYLE.

In discussing the subject of conservatories in the natural style nothing has yet been said respecting the building for the winter garden, conservatory, or whatever name it is thought fit by which to designate it; nevertheless, wherever any attempt is made to carry the project to a successful issue it is of much importance that this most essential point be well considered. By far the greater number of conservatories in this country, large and small, are nothing more than mere creations of the architect, who generally finds a vacant corner into which the introduction of a conservatory will improve the appearance of the mansion, and this without regard to adaptation for the plants it is destined to hold. Therefore, with the exception of roof-climbers, it becomes a mere living sepulchre for the occupants, which can only be kept in anything like tolerable condition by frequent removals, simply through an insufficiency of that greatest of all essentials—light. The fact of every plant which we introduce into our glass houses, and more especially the occupants of the warmest of them being indigenous to countries where they are subject to an amount of light scarcely understood by us in our sunless climate, ought to point to the necessity of making this the first consideration in the matter. And even if it were not a positive essential to the existence of the plants, there is another potent reason in reference to this to be considered, and that is that a conservatory ought to be most enjoyable in winter; yet how often do we find from insufficiency of light that a gloom is cast over the whole of the interior?

The first consideration should be the situation. Unless a conservatory can occupy a position that will afford an abundance of light, and also harmonise well with the architectural features without being made too lofty for the well-being of the plants, it never

ought to be placed in immediate proximity to the mansion; and, wherever it is placed, the internal appearance, when furnished, ought to take precedence over mere outside effect; but where sound cultural and the necessary architectural knowledge are combined, both these essentials might be secured.

The next question is the material—iron or wood. On this subject much difference of opinion exists; each have their advantages. In

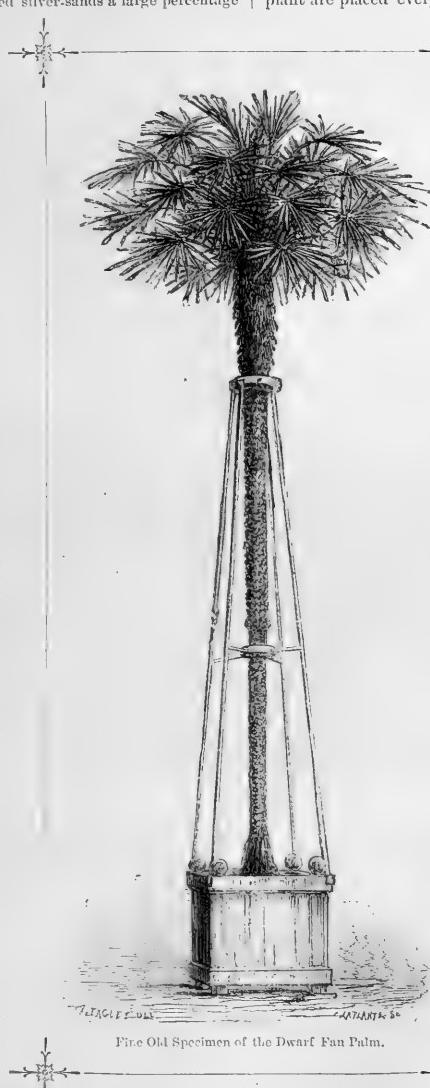

FIG. 1. OLD SPECIMEN OF THE DWARF FAN PALM.

wood, the expansion and contraction consequent upon the changes of our variable climate, are much less than with iron, consequently there is not so much breakage of glass. Against this, iron has the two great advantages of durability, and its greater strength admits of its being reduced in bulk, so as to admit much more light than is possible in the case of wood; therefore I must give the preference to iron.

A third consideration is the form of the building; here there will be room for the exercise of much diversity of taste, and the surroundings in each individual case will in some measure determine the plan: Conservatories of any size, constructed with a single span, internally have an apparent deficiency in breadth, in short, a cramped appearance, and do not afford sufficient scope for anything approaching a natural arrangement of the plants. The best form would be a series of three or five curvilinear spans, according to the length, the centre one being higher than the rest, using iron columns for support, and hollow, so as to take off the roof-water. This form might be varied with a transept, or in other ways, if thought desirable.

As to the distribution of the plants, no set form of arrangement can be satisfactorily given, unless the size of the building was determined on; but, above all things, anything approaching crowding must be avoided, otherwise, it would be impossible to secure the repose which is so essential for general effect. As to the plants that are to be permanently planted out: this will require being done with judgment, considering well what proportion each individual is likely ultimately to attain, and should be confined to such things as are intended to drape the walls with climbers for the roof and the plants that are to fill the most commanding positions in the building. If it were necessary to use only such things as are grown for the beauty of their foliage, or to make the arrangement to consist principally of such, then almost all might be planted out. This might answer in the sunny clime of southern Europe, but during our sunless winters we want a very considerable amount of colour in the shape of blooming plants. Now, I say distinctly, that with few exceptions, these blooming plants must not be planted out, but must be grown in pots, tubs, or similar contrivances. And this for many reasons, the principal one being that it is impossible to regulate the blooming season with plants that cannot be moved. As to the objectionable appearance of the pots or tubs, this might easily be overcome by sinking them to the level of the ground where they are placed; or there are many other devices by which they might be concealed. But, as I attempted to show in my first communication on this subject, unless the selection of the plants is made with care and judgment, failure must follow. Instead of going to the hottest parts of the world for plants of quick growth that will always be struggling to strip the bounds allotted to them, and that require a temperature too hot to render the place as enjoyable as it should be, the selection should be made of such plants as are found in more temperate climates that possess advantages the reverse of those to which I allude.

I have no doubt that a more natural arrangement of our conservatories will gradually take the place of the present system. Fortunately, this improvement in general effect can be attained without sacrificing in any way that excellence of culture on which the gardeners of this country justly pride themselves.

Southgate.

T. BAINES.

I QUITE agree with M. André as to the general principles involved in this matter. Nothing is more desirable than that the structures by courtesy called "green" houses and conservatories should be made a little greener and fresher and more natural-looking than they usually are. This is desirable from every point of view, but especially so for the gardener, who is continually harassed by the present system of filling and emptying the conservatory every second week or so. The success of the plan, however, depends entirely on the selection of the plants; and while M. André's selection of Palms and plants of noble habit is admirable, and embraces a good many things that deserve to be better known, I think he is wrong in enumerating in his last list such subjects as the Sweet Verbena and the Sparmannia. No doubt they would do well, but so would hundreds of unsuitable weeds. It is the noble Palm, Dracaena, and Tree Fern type of vegetation we want; the small-leaved and flowering plants we can add in pots as we like. As types, these are not so welcome for permanent planting as the tropical forms. But the chief reason for employing such plants as the New Zealand Flax, the harder Palms, Tree Ferns, Dracaenas, &c., is because they do not become periodically shabby; do not rush up to the roof hastily and begin pushing through the glass, but remain for years at a time in a healthy and beautiful condition—always in winter or summer ready to gracefully harmonise with any flowering or other plants we can spare to associate with them.—H. VINE.—[We quite concur.]

APHELANDRA CULTURE.

THOUGH common many years ago, these are now not often seen, even among the best-appointed collections of plants. Why should be we cannot tell, for they are not plants of difficult cultivation, neither do they belong to the most fugitive of decorative plants, as the flowers are produced upon branched spikes, and remain in perfection for many weeks. The great drawback is that they are not easy to produce in a dwarf state, and hence, unless great care be taken at the outset, they are apt to run up spindly and produce a single spike of bloom only. To prevent this, it is necessary that the cuttings be taken not more than two inches long, so that the young buds may come pretty close to the ground. The buds are opposite in pairs, and hence the first growth should be two shoots, the second four, and so on, six or eight pairs of shoots making a magnificent plant—such a one as is rarely seen, and will take several years to form. Cuttings may be taken in the spring, when the plants will be in a comparatively dormant state, and possibly many of the leaves will have fallen. Cut the plants down to within the last pair of joints on each shoot from the old wood, and then cut each shoot into lengths close above and about two inches below the joints, making the last cut in a sloping direction, so as to allow a larger surface for the production of roots. To strike the cuttings readily a brisk, moist bottom and atmospheric heat is necessary—in fact, indispensable. The cuttings are best put in singly in small pots, as then they sustain very little check in removal. When they are struck allow the shoots to grow on, removing them into larger pots as it may become necessary, until they are six or eight inches high, and then, when the pots are full of roots, stop each shoot back to the lowermost pair of buds. From these four pairs of shoots should be produced, and when these have attained sufficient strength they also may be stopped back, if they are vigorous at the time eight pairs of shoots may be the result. This, technically speaking, may be called forming the bottom, a process which may result in fine plants another season, but not in those which will produce flowers the first. But never mind that; take care to get the last set of shoots well grown and thoroughly ripened, and then gradually dry off and put the plants to rest for the winter. They must not be kept absolutely dry for the winter; but no more water must be given than will be requisite to keep the plants from shrivelling.

With plants for blooming it will be necessary to grow them right on from the cutting state, giving them none of the checks of the stopping process, but encouraging them to grow as strongly as possible. For this purpose a brisk growing temperature of 70 degrees, rising to 90 degrees with sun heat, is necessary, and if at the same time bottom heat can be given, it will be so much the better. Cuttings rooted in small pots may be removed to four-inch, again to six-inch, and if they are very robust, to eight-inch pots, of course watching the right time for these several removals. The best compost for the strong-growing kinds is rich turfy loam three parts, and a fourth of rotten dung well incorporated, to which must be added sufficient sand, charcoal, and crushed oyster-shells to make it light and friable. Pot firmly at all times, but especially when the plants receive their last shift for the season. To ensure their blooming, the plants should be kept in full lights, and as near to the glass as possible; but at the same time, as the leaves are thick and coriaceous, to prevent their scorching it will be necessary to shade them in bright sunlight. This, however, will depend upon the quality of the glass. If it is good and free from convexities, no shading will be necessary; but if not, it will be safest to throw a slight shade over the plants in bright sunlight. The plants may be made to bloom at any time from October, or earlier, to March, according to the temperature in which they may be placed; but all attempts to prolong the blooming beyond that season and into the early spring have signally failed. When they have ceased blooming reduce the supply of water, and remove the plants into a lower temperature. The time for cutting them down must be regulated by the season in which it is desired that the plants should bloom. It is best to divide the stocks of the plants into three or four sets, and, by introducing a set into a higher temperature every month, a succession of bloom may be had from October to the end of March.

In speaking of the old plants, in successive years the young shoots must be boldly cut back to the lowermost pair of buds upon each branch, then syringe them daily, limiting the supply of water at the root. In a short time the buds will begin to develop themselves, and then the plants must be shaken out, the roots curtailed, and repotted into small pots in the compost previously named. After this bottom heat may be applied with advantage, and the plants may be grown vigorously on, of course guarding against those insect pests to which almost all plants are subject. The preceding remarks apply in the main to that old favourite species, *A. cristata*, but they are also applicable to *A. aurantiaca* and *Roezlii*, though these, being more delicate in habit, will require the compost to be very turfy, with an addition of peat; and, until they become well established, should have limited pot room and careful watering. Two more beautiful plants when properly grown it would be difficult to conceive. The regret is that we see them so rarely. In addition to the above we may specify *A. nitens*, a recent introduction from Guayaquil, which blooms in May. *A. Siboniana*, from Brazil, is another spring-flowering species of great beauty. These two species we should specially recommend to our great plant growers as being worthy of their attention for exhibition purposes.

W.

PALMS FOR THE GARDEN.

(Continued from p. 283.)

COCOS AUSTRALIS (SYN., *WALLISHII*; *PARAGUAY*).—Habit, dense; fronds, recurved; pinnae, regular, narrow, channeled on the underside; a character which also belongs to all the species. A good greenhouse palm, the fronds of which are more like those of a *Phoenix* than those of others of the genus.

C. BOTRYACEA (SYN., *BOTRYOPHORA*; *TROPICAL AMERICA*).—Fronds, when young, erect, when old, drooping; pinnae, regular, lax. Very ornamental when about ten, or from that to sixteen feet in height, the whole plant then being very erect, and forming a striking object among large-foliated plants.

C. FLEXUOSA (BRAZIL).—In general habit allied to the last, except as regards the pinnae, which are arranged in sets of from eight to ten. Very ornamental.

C. NUCIFERA (*COCOA-NUT PALM*; *INDIAN ARCHIPELAGO*).—Fronds very stout compared with those of the other species; pinnae, regular, two inches broad. A well-known and noble palm for large stoves; fond of water and heat, and so fast a grower as soon to get too large for general purposes. Of this species there is a fine variety called the "King," with a yellowish tint in the foliage, altogether a stronger plant than the last, of which, moreover, there are some twenty other varieties, some smaller than the normal kind, but not in cultivation in this country.

C. PERNAMBUCENSIS.—A lax, bad grower, and not useful.

C. PLUMOSA (SYN., *COMOSA*; BRAZIL).—Erect; pinnae, irregular. Of the erect-growing section of this genus, this is the best, though all are good. Where a slim, tall plant is required to break a line or give elegance to a lofty stove, such palms as these are useful, giving to such positions a very tropical effect.

C. ROMANZOZZIANA (BRAZIL).—Erect; pinnae, regular, narrow, and lax.

C. SCHIZOPHYLLA (BOLIVIA).—Fronds, reflexed, long; pinnae, regular; petioles brown, with spines at base. A tall-growing species, with the habit of a *Phoenix*. A very ornamental conservatory palm.

C. WEDDELIANA.—Fronds, gracefully spreading; pinnae, one and

a half inch wide, regular, glaucous. The most elegant species of this genus; when not more than four feet in height, young plants of it have often as many as twelve and twenty graceful fronds on them, forming a plume of the most beautiful description.

COPERNICIA.—A genus of Tropical American palms, having foliage similar to that of *Latanias*, but irregular and sparse; therefore not desirable in an ornamental point of view. The species are *cerifera*, *tectorum*, and *palmata*, the last of which is the best; foliage nearly round and dark-green.

CORYPHIA AUSTRALIS (SYN., *LIVISTONA*; NEW HOLLAND).—Fronds, palmate, cut half-way, forming almost a circle; spines on the petiole, small and recurved; fibre at base brown. An excellent greenhouse palm or for setting out of doors in summer. It is not a very fast grower, and may be kept in a room for a long time without injury.

C. UMBRICALIFERA (CEYLON).—Fronds, palmate; petiole with small spines on margin. A very slow-growing palm, and one which forms very strong roots, unfitting it for pot culture.

DIPLOTHrixMIUM CAUDESCENS (BRAZIL).—Fronds, from twelve to twenty feet, two feet six inches wide, nearly erect, regular, pinnate, channelled on the underside, and white; upper surface dark green; unarmed. A noble palm for a large house, the nearly erect fronds, showing the white undersides, being very effective; moderate heat is sufficient for it.

D. LITORALE (BRAZIL).—A lax, useless plant for decorative purposes.

D. MARITIMUM (BRAZIL).—In general aspect like *caudescens*, but dwarfer and denser.

ELEIS GUINEENSIS (THE OIL PALM; WEST TROPICAL AFRICA).—Plant, dense; fronds, erect and spreading; pinnae, regular, channelled on the underside, recurved; base of petiole spinose; fronds, fully developed, plant from eight to ten feet. When young, this makes a good plant, as well as a good useful plant for decoration, being of light feathery habit, and it will last well in a small pot for eight or ten years. When old, it gets rough; it is fond of heat and water.

E. MELANACOCCA (BRAZIL).—In general appearance like the last, but slender, and without spines; a good palm. J. CROUCHER.

(To be continued.)

Window Box furnished with Dracenas.

THE GARDEN IN THE HOUSE.

DRACENAS AS WINDOW PLANTS.

But a few years ago Dracenas were only known in collections of choice greenhouse plants, and like many other things, it was formerly supposed that they could only be grown by skilful gardeners. They have been found to endure, however, and even flourish under very ordinary treatment. The increased taste for and general use of hanging-baskets and window-boxes have made plants formerly rare in such positions now quite common. Dracenas, as will be seen by our illustration, have a fine appearance in window boxes, and they also look well in Wardian cases. Dracenas, as is doubtless well known, belong to the Lily family, but they do not have showy flowers, and are cultivated solely for their foliage. Many of them have red coloured foliage, and others present different shades of green. There is considerable difference in the width and thickness of the leaves, and all have a pleasing tropical habit. They endure the dry air of our dwellings with impunity. The tall specimen in the centre of the box is *Dracena indivisa*; the two smaller ones are, *D. terminalis*, with reddish foliage, and *D. anustralis*, with broad green leaves. Some *Tradescantia repens* is put in as a covering to the soil, so as to give the box a pleasing appearance.—*Hearth and Home*.

CULTURE OF PLANTS IN ROOMS.

(Continued from page 199.)

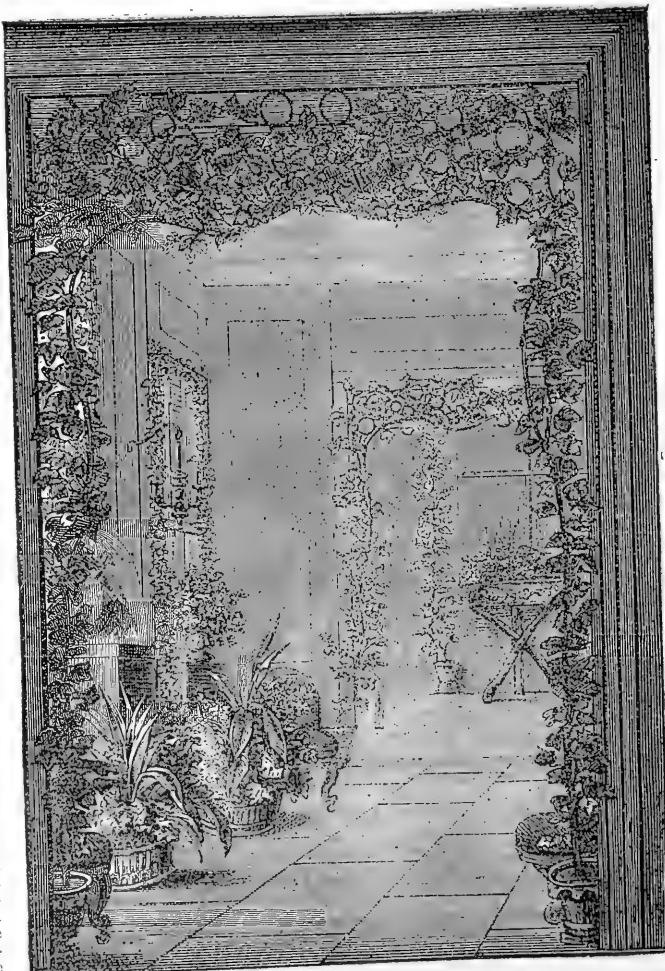

Our illustration is intended to furnish a view of plant arrangement in a room which is lighted on one side only. Ivy and the antarctic vine here form an important part of the decoration. The baskets of plants on the floor are placed at just such a distance from the wall that the light from the windows may fall directly on them. In place of these, flower-stands may be used, placing them directly opposite the windows. The parts of the wall between the windows are very unsuitable positions for flower-stands, although one often sees them placed there.

In dwelling-rooms, properly so called, plant decoration, as we have hitherto described it, cannot be carried on, as it would either darken the rooms too much, or would deprive the mistress of the house of the window recess in which she loves to sit at a table with her work. But even in Russia, when nature out of doors lies dead and the earth is covered with a shroud of snow, we can obtain the greenness of vegetation, so soothing to the eyes and so cheering to the mind, by constructing bowers or canopies of ivy or Cissus, at the window and only a little broader than it, so that they may be in a line with the side-walls of the window recess. The plants placed in the window here should not be too large, and then the mistress can sit at her work-table in a green bower in the middle of winter, the dimensions of space in the apartment being very little entailed thereby. But these rooms generally have several windows, one or other of which may, without detriment to the light or the use of the apartment, be devoted entirely to plants, in which case boards or shelves may be placed one over another, and on them may be cultivated ornamental foliage plants, or flowering plants, or the windows may be converted into double windows, the construction of which will be explained further on.

THE ARRANGEMENT OF PLANTS IN ROOMS, CORRIDORS, CELLARS, &c., WHERE THE TEMPERATURE IS ABOVE THE FREEZING POINT.

We must here, as in the foregoing remarks, make a distinction between the arrangement for ornament, and the arrangement for culture only. With respect to the arrangement for decorative purposes in rooms not usually occupied, but which maintain a temperature above the freezing point, or in corridors, on staircases, &c., with a similar temperature, the instructions already given will be equally suitable, and the only difference will be in the selection of the plants. Hardy evergreen greenhouse plants may be employed here during the period of rest, and, so long as they do not make a fresh growth, may even be placed during the winter in positions at a distance from the light without suffering any harm. But as soon as the new growth commences, they must be transferred to positions which are better lighted.

In the greater number of cases, greenhouse plants, whether they be evergreen foliage plants, or flowering plants, are not brought by the amateur inside the dwelling-house for decorative purposes, but partly in order to produce flowers for winter-blooming, partly to fill flower-stands before the windows in summer, and partly for the open-air decoration of balconies, verandahs, &c., during the summer. Therefore in cultivating them in rooms, the winter period is the chief one which requires attention. Hardy kinds which can endure some degrees of cold unsheltered, and which maintain a perfect state of rest all through the winter, may be wintered in places

Room Plant-Culture at St. Petersburg.

feebly lighted, or even almost dark, such as cellars, vaults, &c. As in such places all depends on keeping the plants in a state of rest, the temperature should range from 1° to 3° above zero. The positions of the plants are to be looked to, so that they will be injured neither by too much moisture or damp air, nor by dust or too dry air. In the first case mouldiness and decay, and in the second the drying up

of the plants will inflict much damage. Thorough ventilation will prove of considerable service during the winter. Cellars in which fermentation is carried on, dry heated vaults, fruit cellars, &c., are consequently unsuited for the wintering of plants; while half-lighted, dry cellars are most favourable. Deciduous shrubs, and shrubs in pots, and even hardy evergreens, are more easily wintered in such localities, in proportion as the mildness of the climate allows them to be brought in late in the season, and to be brought out again early in the following spring, before the new growth begins.

A room with a temperature above the freezing point is an excellent place for wintering the greater number of those favourite greenhouse flowering plants, the flowers of which fall off principally in the summer months, such as Pelargoniums, Heliotropes, Fuchsias, &c. In this case, where it is possible to have such an arrangement, the plants should be placed on tables or stands which run across the window, and at just such a distance from it, that the parts of the wall between the windows may not hinder the light from falling directly on the plants. Stands with steps from top to bottom, and rising from the window, which are not more than a foot broad at the most, are the most suitable arrangement, because on them the plants are so distributed that each receives more light than if they were arranged on tables. When a stand of this kind is used, there should be either no plants or only very small ones placed between it and the window, so that the plants on the stand may enjoy all the light possible. The space behind the stand and under it may be utilized for the wintering of deciduous plants, hardy evergreens, and, above all, hardy greenhouse plants in a state of rest.

When the room is not to be entirely devoted to the wintering of plants, several boards may be placed in the window, at a distance of two feet one above another, on which the smaller plants may be placed. Other and larger plants may be set on separate stands at just such a distance from the window as to permit access to the smaller plants which are placed there. Ventilation in mild weather and a careful observance of the temperature, so that frosty air may not enter during a sudden change in the weather, are two points which require to be especially attended to.—*From the German of Dr. Regel.*

NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

Rose and White Flowered Lapagerias.—The rose-coloured Lapageria and its white variety, on account of the size, form, consistence, and durability of their flowers, are among the most choice and valuable for cutting. The latter is a most important quality most fully developed in the Lapageria. The flowers have a wax-like consistency that preserves them from fading for days, or even weeks. Pendent branches, hung thickly with rose pink or white bells, are simply magnificent for vase and basket work, the effect being unique and imitable. The flowers strike one at once as of the highest quality, while their size adapts them admirably for large vases, &c. A vase filled with Brugmansia suaveolens, with Lapageria roses fringing its sides, has a magnificent effect. Single flowers, set in green moss or fern, are telling in flat arrangements. I hardly venture to write how long the flowers will keep fresh in such positions. Then, for centres or for forming hand bouquets, the Lapageria mounted singly furnishes material of the first quality. A single flower of either the rose or white variety forms an exquisite eye or centre. Both colours may be used in the bouquet with good effect. A white centre, with three or five rose-coloured flowers round it, forms, with green backing and fringe, and a little “stabbing” of Lily of the Valley, Hosta japonica, violets, or nigoniroot, or other slender flower, for contrast and perfume, a perfect bouquet. A rose centre with white around is equally beautiful, and more chaste. The white variety gives quite a new character to wedding bouquets. This is a great boon; for few arts are more difficult than the securing of variety in bouquets spotlessly white and green only. The novelty of form, too, in the Lapageria is an advantage to the maker of wedding bouquets. Standing up, the white cup-like flowers remind one of spotless goblets offered to the bride. The only difference in the two varieties is that of colour; in all other respects they appear identical. The white does not manifest that great weakness even though often appears in white varieties, as if white were indeed the breath of consumption, or the pale touch of early death. Still, the white variety is not yet generally cultivated, though it ought to find a place in every garden.—D. T. F., in “Field.”

A New Floral Ornament for the Drawing-room.—Last August a lady friend of mine gathered a handful of the world-renowned flowers of Forget-me-Not, Myosotis palustris, and to preserve them for as long a period as possible they were put in a large soup-plate filled with rain water. The flowers were placed near the window, so as to enjoy the advantages resulting from an abundance of light and air, and the water

was replenished when needful. In a surprisingly short space of time—three weeks, I believe—white thread-like roots were emitted from the portion of the flower-stalks in the water, and they ultimately formed a thick network over the plate. The flowers remained quite fresh, excepting a few of the most advanced when gathered, and as soon as the roots began to run in the water the buds began to expand, and to take the place of those which faded; and up to the middle of November the bouquet—if it may be so-called—was a dense mass of flowers; and a more beautiful or chaste ornament for the indoor apartment cannot be imagined.—*Thomas W. Gruesler, in “Gardener’s Magazine.”*

Goniophlebium appendiculatum.—It is well known that many fern leaves, even when they are matured, will not stand long in water after being cut—one or two days at the most will suffice to finish their beauty. Even the Maidenhair, though quite matured, will not stand more than three days. I may mention, however, that this species of Goniophlebium appendiculatum, fronds of which when dried, will keep in a perfect state. It is a warm greenhouse kind, and like most of the valuable winter decorative ferns, is most impatient of heat. It should never be allowed to get dry, and a saucer of water at the roots in summer will assist it very much to mature its numerous fronds for the winter months, when they are found really valuable.—H. K., in “Gardener’s Chronicle.”

THE PROPAGATOR.

THE ART OF GRAFTING.

(Continued from page 276.)

METHODS OF GRAFTING.

THESE are numerous, and vary according to circumstances, being not unfrequently the result of chance, or the fancy of the operator. From our own experience and observations we shall describe the modes which are most useful. By modifying them in one way or other the number may be increased; but all may be referred to the types which we shall describe, and may be employed with the same results. A systematic classification of them is difficult, on account of their number, and the almost invisible lines of demarcation by which some of them are divided from each other. They may, however, be grouped into three great divisions, viz.:—Grafting by approach, or inarching; by detached scions; and by detached buds.

In the descriptive part, under each subdivision, we shall give the title by which each particular operation is known. We have arranged the subject in the following order:—

GRAFTING BY APPROACH.

Group 1.—Method by veneering.
 , by inlaying.

 English method.

Group 2.—Inarching with an eye.
 , with a branch.

GRAFTING BY DETACHED SCIONS.

Group 1.—Side grafting under the bark.
 , with a simple branch.
 , with a heeled branch.
 , in the albumen.
 , with a straight cleft.
 , with an oblique cleft.

Group 2.—Crown grafting.
 Ordinary method.
 Improved method.

Group 3.—Grafting *de précision*.
 Veneering, common method.

 , in crown grafting.

 , with strips of bark.

Crown grafting by inlaying.

Side grafting by inlaying.

Group 4.—Cleft grafting, common single.
 double.

 , oblique.

 , terminal.

 , woody.

 , herbaceous.

Group 5.—Whip grafting, simple.
 complex.

Saddle grafting.

Group 6.—Mixed grafting.

Grafting with cuttings.

When the scion is a cutting.

When the stock is a cutting.

When both are cuttings.

[FEB. 24, 1872.]

ROOT GRAFTING.

Of a plant on its own root.
on the root of another plant.
Grafting with fruit buds.

BUD GRAFTING (BUDDING).

- Group 1.*—Grafting with shield buds.
Bud grafting under the bark, or by inoculation.
" ordinary method.
" with cross-shaped incision.
" with the incision reversed.
" by veneering.
" the combined or double method.
Group 2.—Flute grafting.
" common method.
" with strips of bark.

GRAFTING BY APPROACH.

GENERAL INSTRUCTIONS.—Grafting by approach is the most ancient of all the methods of grafting. From time immemorial nature has given examples of it in our forests, hedges, arbours, &c., where we find trees joined together by their branches, stems, or roots, from long continued contact or rubbing. Grafting by approach, then, consists in uniting two trees by their stems or branches. In certain cases, the shoot of a tree or plant is thus grafted on the parent stem or branch. The season for grafting by approach commences and ends with the flow of the sap, from March to September. The stock and the scion may be in the woody or the herbaceous state, the mode of operation being the same in both. In grafting by approach, the scion is not stripped of its leaves, as in the other modes, because it remains attached to the parent plant while it is being joined to the stock. From both scion and stock a precisely similar portion of wood and bark is removed, so that the parts may fit exactly when they are put together. In order to promote their union, the graft is bandaged, and covered with grafting wax. In the case of two trees being grafted together, a prop, or stake, is used. After they have continued to grow together for, at least, a year, when the union may be considered perfect, the part grafted on the other may be detached from the parent stem. The modes of grafting by approach may be divided into two classes:—First, those ordinary methods, in which the upper part of the scion is retained after it is joined to the stock; and second, the process named "marching," in which the cut top of the scion is inserted under the bark of the stock.

Veneer Grafting by Approach.

GROUP I.

ORDINARY GRAFTING BY APPROACH.—The scion is a tree, or a branch of a tree, distinct from the stock, or a branch belonging to the stock itself. The top of the scion is kept entire above the point of contact with the stock: however, if too long, it may be cut above the graft, leaving two or three

eyes if it be a single shoot, and a length of four, eight, or twelve inches if it be a ramified branch. There are different ways of joining the scion and stock, named after other modes of grafting, as by veneering, by inlaying, and by the English method.

VEENEER GRAFTING BY APPROACH.—The scion (A) has a portion of the bark and albumen removed at *a*. In the stock (B) a flat-bottomed groove is made at *b*, reaching to the albumen, and corresponding in dimensions to the part *a* of the scion. The metro-greffe will be useful here in adapting these two parts accurately to each other. They are then joined together at C, bandaged and covered with grafting-wax if necessary.

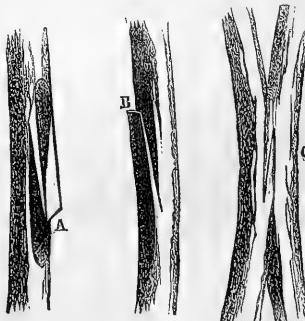

APPROACH GRAFTING BY INLAYING.—The scion (D) is slightly cut on both sides at *d*. The stock (E) is prepared to

Approach Grafting by Inlaying.

receive it by having an angular groove made at *e*, into which the bevelled part *d* will fit accurately, and be inlaid, as shown at F.

ENGLISH METHOD OF APPROACH-GRAFTING.—In addition to bandaging, the parts may be still more firmly consolidated by means of corresponding tongues or notches (A and B) cut in

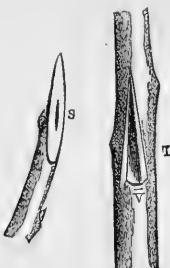

English Method of Approach-Grafting.

each, so as to fit exactly into each other as shown at C. If it is apprehended that the union of the parts will be tedious, the top of the stock is cut off at the time of grafting, and the scion joined to its extremity. This is called the English method.

GROUP II.

APPROACH-GRAFTING BY INARCHING.—Although more particularly employed for restoring defective parts of plants and trees, this mode of grafting by approach is equally useful for multiplication. The proper time for it is from April to July. The chief difference between this and the preceding group consists in the cutting off the top of the scion, whether tree or branch, and the inoculation of the top so cut under the bark of the stock. The cutting of the scion is made under an eye or a shoot, so that one or other may be set in the stock. This scion, having been topped and bent in the manner represented at S in our illustration under the terminal bud or shoot, is grafted into the stock by means of a reversed T-shaped incision in the bark, as shown at V. The place of the incision is calculated from the length of the scion, which should be an inch or so longer, so that in inserting it into the

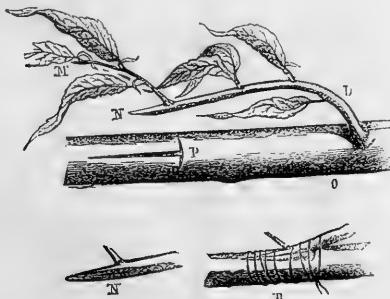

Approach Grafting by Inarching,

incision it is first slightly bent, drawn back, and the point then allowed to slip under the bark. The two principal modes of inarching are only to be used during the flow of the sap, in spring or in summer.

INARCHING WITH AN EYE.—The eye being selected like the terminal bud, the scion is cut at the end with a flat splice-graft, as shown at S. It is then inserted under the bark of the stock T, which is raised at V. We shall re-produce hereafter the same graft completed and beginning to vegetate. When the bark of the stock is thick, an incision is made with a double longitudinal cut, the intervening strip of bark is raised at one end, and the top of the scion is inserted under it. Neither the strip of bark nor the bandage should cover the eye of the scion.

INARCHING WITH A BRANCH.—The scion (L) bearing a young lateral branch (M), is to be cut about an inch above it, in a sloping direction (N), on the side next the branch. Care should be taken not to cut the end too thin; and the leaves

Inarching with a Branch.

are not to be removed from either the branch or the scion. The stock is either a distinct tree, or a branch (O) bearing the scion. The incision (P) is made in such a manner that the introduction of the scion is effected as represented at R. The branch (M) may be left entire or cut down to two eyes,

according to its length. It is called an "anticipated branch" if it has been produced in the course of the year on the herbaceous scion, in which case the grafting would take place in summer. It is called a "branch" simply, if it has been developed in the spring on the woody scion, or in the preceding year on the main branch. In this case, the grafting would take place from April to June.—*C. Ballet, "l'Art de Grefyer."*

(To be continued).

ANOMALOUS GRAFTING.

YOUR correspondent, *agropus* of anomalous grafting, in your number for December 30th, p. 122, whilst asserting that Virgil speaks of "a plum tree which bore apples after being grafted," and "recommends the grafting of the pear on the ash," mis-states Virgil's drift in his second clause, and in his first confounds his authority with that of Palladius, a Latin horticultural writer of the fourth century after Christ. Of what Virgil had to say on grafting, Mr. R. D. Blackmore's version of the "Georgics" gives a fair transcript:—

"But just as grafted on the rough auburn,
And barren pines bear apple-trees in fruit.
With chestnut bloom the beach is silver-laid,
The mountain ash in white pear-flowers array'd,
And swine crunch acorns in the elm tree's shade."

—*Georgy. II., 69.*

Palladius has not found a translator that I know of for his poem on grafting, but I give his lines *ad rem*, and a rough and ready version of them:—

"Insita proceris pergit concrescere ramis,
Et sociam mutat malum amica pirum;
Seque feros silvis hortatur lignera mores,
Et parte gaudet uobliuore frui.
Spiniferus prunus, armataque rotora, sente-
Levigata, et pulchris vestit adula cornu;"

—77-32 *Palladius De Inustione.*

The engrafted apple, blending kindly growth,
Transforms the kindred pear tree, nothing loath;
Leaves barren habits in the natal bough,
And joys to yield a fruitage apt for food.
Makes smooth the spiny plums and prickly thorns,
And with gay foliage novel boughs adorns.

In the context to these lines the author describes how the service tree (*Sorbus*) and the medlar (*Mespilus*) owe to the apple the same insstitial improvement.

JAMES DAVIES, M.A.

L A W.

IS A GREENHOUSE A CHATTEL OR A FIXTURE?

THIS case was heard before Mr. Justice Quain, in the Court of Queen's Bench, on the 5th instant, and was an indictment removed into this court by *citeriorari*, the prosecution being instituted for a conspiracy under the Malicious Injuries to Property Act, and the penal sections of the recent Debtors Act. The defendant, Mr. D. Perkins, was a nursery gardener and florist, and held a lease of his house and gardens in St. John's Wood Terrace. In 1869 he obtained an advance of about £117 on the security of this lease from the Model Discount Company. The advance, it appeared, was not repaid, and in June 1870 he filed a petition for the liquidation of his affairs under the Bankruptcy Act. During his tenancy he erected four greenhouses on his premises, the brickwork and foundations being there when he came into possession. The evidence was that these were not fastened into the brickwork, but laid upon it so as to be fixed only by their own weight. While the liquidation proceedings were pending it was alleged that the defendants took down and removed three of these greenhouses, and a prosecution was then instituted against them for conspiracy under the above Act. The case for the defence was stated to be that they had been sold before the liquidation by Mr. D. Perkins to his co-defendant, a Mr. Tindal. A somewhat curious point arose as to whether a greenhouse erected in the way described was a building, or fixture, within the meaning of the Act for preventing malicious injury to property. The facts turned upon the alleged removal by the defendant of the greenhouses after a distress for rent and after the presentation by him of a petition for liquidation. The learned Judge ruled that the greenhouses were not "buildings or fixtures" within the meaning of the first-mentioned Act, and that the defence might be confined to the question whether they had been removed fraudulently with the object of defrauding creditors within four months of the commencement of the liquidation. The case for the defence was that the greenhouses had been sold by one of the defendants, D. Perkins, to a co-defendant, one Tindal, some time before both the distress and the liquidation proceedings. The jury

found the defendants D. Perkins and Tindal guilty, and acquitted the third defendant, Frederick Perkins, who, it appeared, had only acted as gardener and labourer for his father, D. Perkins. The learned Judge ordered D. Perkins and Tindal to stand forward, and sentenced them to be imprisoned—D. Perkins for two months, and Tindal, as the principal offender, for three months, in each case without hard labour.

THE AMATEURS' REMEMBRANCER.

Flower Garden and Shrubberies.—Herbaceous borders dig lightly over, taking care not to injure the roots of the plants; loosen the surface of spring flower-beds, and make all appear neat and gay. Rectify the edges of grass verges, gravel walks, and lay box edgings. Lawns sweep and roll. Roses prune, and firmly stake. From those on walls and pillars remove dead wood; thin them, and neatly tie them up again. Beds and borders of American plants, dress with a covering of decayed leaves. Plant out Pansies, wintered in frames, press the soil firmly about their roots. Where Auriculas are planted, loosen the soil to the depth of two inches, and top dress with cow-manure, leaf-mould, sand, and charcoal. Plant out Hollyhocks four or five feet apart in deep rich soil.

Indoor Plant Department.—In conservatories, which should now everywhere sparkle with floral beauty, maintain a night temperature of 45°, and while the weather is so favourable give plenty of air. Let nothing suffer from want of water, and plants beginning to grow syringe morning and evening. Climbers, thin and tie where required. Keep up a regular succession of blooming plants, and those done flowering remove. Calladiums, Gloriosias, Gesneras, &c., showing signs of growth, pot, and place in a nice bottom-heat of 75°. Marantas, Dieffenbachias, Dracanas, tropical Palms, &c., repot, and keep in a warm, moist atmosphere, and where convenient, a brisk bottom-heat should be given. Pot Sarracenia in rough bits of turf peat mixed with a little silver sand. Ferns not already potted, should receive that attention at once, and where ferneries are out of repair, they should be renovated. Orchids beginning to grow may receive more water, but at present, they must be kept rather dry at the root; encouraging a moist, fresh, and healthy atmosphere, by frequent sprinklings of water on the floor, walls, tables, &c. Shade from bright sunshine, and give a little air, but avoid cold draughts.

Pits and Frames.—A regular supply of Lilies, Azaleas, Spiraeas, Deutzias, bulbs, &c., should be introduced to the forcing-pit, for conservatory decoration hereafter. Propagate Coleus, and pot those already rooted. Alternantheras shake out of their cutting pots, and pot off singly into small pots. Dahlias and Cannas, start in gentle heat; sow a few choice annuals for indoor decoration on a gentle hot bed; those already up should be pricked off into shallow pans. Gloriosias, Gesneras, &c., as they begin to grow, shake out, and pot them, plunge them in a gentle bottom heat. Chrysanthemums, if rooted, should be potted singly, and kept near the glass, shading from strong sunshine for a few days. Sow Lobelias in pans or boxes, prick off those sown in autumn, and plants from cuttings should now be placed in heat for propagating from. Tropaeolums, introduce into heat for cuttings; Fuchsias, prune, and place in gentle heat, for early flowering and for cuttings. Stocks in frames, as soon as they show flower-buds, and the single ones can be known from the double, should have the former pricked out, and thrown away, and the latter potted. Geraniums and other bedding plants should receive all the air possible; young plants may be repotted, and where two or three are in one pot, separate them, and pot singly. Propagate by inserting in sand in a hot-bed of 60° or 65°. Verbenas should now be kept in heat for cuttings, which should be placed in a hot-bed, and kept near the glass. As soon as rooted, pot off singly, and plunge in bottom heat, so that the points of the young plants may be taken off, and struck. Salviae, Heliotropes, Ageratines, &c., may be similarly treated. Camellias should now be grafted, or inarched, keeping them rather close afterwards for a time.

Indoor Fruit Department.—Pine-apples, pot as they require it; they may now receive more water and heat than they have been getting; keep up a bottom heat of 55°, and maintain a steady growth. Those colouring fruit require a drier atmosphere and more air than succession plants. Vines setting require a rather dry atmosphere; for Muscats, a night-temperature of 70°, and for Hamburgers, 65°. Thin and tie, and syringe frequently those starting. Before and after the fruits is set maintain a moist atmosphere. To figs give plenty of water, and keep up a temperature of from 60° to 65° at night; pinch the young shoots at their fourth or fifth joint. Peaches and Nectarines set may have a temperature of 60°, not more; syringe frequently, and give plenty of air, avoiding draughts; for those in flower, maintain a temperature of 50°, keeping the atmosphere dry, and admitting air whenever that can be done. Strawberry plants introduce every fortnight to shelves near the glass; pick off small flowers, and when a sufficient quantity is set, remove the rest.

Hardy Fruit and Kitchen Garden.—Finish planting fruit trees and bushes, also pruning and nailing. Blossom protection look to, adopting some of the modes of protection given in another column. Ground vacant dig, and trim edges of alleys. Grafting may now be commenced. Sow Onions on well-prepared ground; plant some bulbs for seed in an open situation, and cover to the depth of six inches. Peas and Beans sow for succession. From Lettuces in frames remove the sashes in fine weather, and sprinkle with lime, to keep off snails, &c., and make good blanks. When Lettuces are sown in frames with Carrots or Onions, the former should be removed, and the latter thinned and

regulated. From Cauliflowers, remove the handlights in warm weather. Radishes, sow successively, covering with litter till they appear, after which the litter may be removed. As soon as Broccoli is cut, replant the ground. Early Turnips sow, also prickly Spinach and early Cabbages. Potatoes forwarded a little in boxes, plant out in a warm, sheltered border; early potatoes may also be planted in the open ground.

A NEW LONDON PARK.

The contractors of the Metropolitan Board are now engaged in the rapid completion of what will be one of the best of the public gardens of the metropolis; and by the spring it is hoped that it will be ready for the recreation of the public. For many years past the large open space known as Stepney Green, which is situated in the heart of the most crowded quarters of the East of London, had fallen into a neglected condition, and its enclosure and adornment having become the subject of discussion at the local board, the Mile End Vestry, an appeal was made to the Metropolitan Board. After a brief delay, the Metropolitan Board consented to contribute the whole cost—about £3,000—of converting the fields into flower gardens and a public recreation ground. Stepney Green, apart from its sanitary value as one of the very few open spaces in the East of London, has many interesting historic associations. It is the last remaining remnant of the once famous Mile End Green, the trysting-place of the civic archers of the Tudors, and the rendezvous of the rioters of Essex in the insurrection led by Wat the Tyler in 1381. By a patent granted under the seal of the Second Charles an annual market and fair was held on Mile End Green at Michaelmas; but this has shared the fate of other metropolitan fairs. It is only within the last century that some of the houses of the Stuart nobility which stood on Stepney Green, and marked the spot as a once fashionable quarter, were demolished; and so recently as 1859 a large castellated mansion belonging to the Marquis of Worcester, and commonly known as "King John's Castle," was still standing in excellent preservation. The Lord of the Manor of Stewsbury has now granted Stepney Green for the free and perpetual use of the people as a recreation ground, and, except in regard to the expenditure for enclosure and culture, this valuable open space, which contains many noble and venerable trees, has been secured to the public without cost.—Metropolitan.

COVENT GARDEN MARKET.—February 24th.

Flowers.—Conspicuous among flowers, representatives of which are now everywhere in blossom out of doors, are Violets, Crocuses, Snow-drops, Christmas Roses, Arabis, Aconites, and one or two species of Saxifrage; while, from frames we have the lovely Winter Windflower (*Anemone blanda*), which often opens its charming deep-blue blossoms as early as Christmas. Cyclamens, Primulas, and Polyanthus—those never failing harbingers of spring may be obtained in abundance; and those ever-pleasing occupants of our hot-houses, Orchids, there is no scarcity, either as regards quantity or variety. Other flowers consist of Spiraea, Daphnes, Heaths, Epacries, Roses, Acacias, Camellias, Deutzias, Lilacs, Cyrtisus, and others.

Prices of Fruits.—Apples, Dessert, 2s. to 4s. per dozen.—Cobs, per 100 lbs., 6ds. to 6s.—Fibberts, per lb., 8d. to 10d.—Grapes, per lb., 6s. to 12s.—Lemons, per 100, 7s. to 10s.—Oranges, per 100, 6s. to 10s.—Pears, per dozen, 3s. to 8s.—Pine-apples, per lb., 6s. to 10s.

Prices of Vegetables.—Artichokes, green, each, 6d. to 8d.—Asparagus, per 100 lbs., 8s. to 10s.—Beet, per dozen, 1s. to 2s.—Broccoli, purple, per bundle, 10d. to 1s. 3d.—Brussels Sprouts, per half sieve, 2s. 6d. to 3s. 6d.—Cabbages, per dozen, 10d. to 1s. 3d.—Carrots, per bunch, 5d. to 7d.—Cauliflowers, per dozen, 2s. to 6s.—Cucumbers, each, 1s. 6d. to 3s.—French Beans, new, per 100, 3s. to 4s.—Herbs, per bunch, 2d. to 4d.—Horse Radish, per bunch, 3s. to 5s.—Leeks, per bunch, 2d. to 4d.—Lettuces (French), Cabages, per dozen, 1s. to 2s. 6d.—Onions, per bunch, 4d. to 6d.—Parsley, per bunch, 2d. to 4d.—Radishes, per bunch, 2d. to 6d.—Rhubarb, per bunch, 6d. to 1s. 6d.—Salsify, per bunch, 1s. to 1s. 6d.—Scorzonera, per bunch, 9d. to 1s. 3d.—Seakale, per punnet, 1s. to 2s.—Shallots, per lb., 8d.—Spinach, per bushel, 3s. to 4s.—Tomatoes, per small punnet, 3d.—Turnips, per bunch, 3d. to 6d.

Readers who may find it difficult to procure THE GARDEN regularly through the newsmen, may have the numbers sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsmen, at the railway book-stalls, and from the office.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

GARDEN

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

THE FLOWER GARDEN.

THE ROSE SECRET.

THERE is no mystery whatever in raising roses in any quantity by means of cuttings, and thus making them much cheaper than budded ones. Where cuttings can be had in quantities, the best time to put them in is October, on a sheltered south border, into which plenty of sand has been worked to make it light. If frames can be put over them, they will strike quicker and be safer in severe winters than when unprotected. In making the cuttings a small piece of the old wood should be left attached to the end inserted in the soil, as it calluses sooner for the emission of roots than when only the current year's wood is used. Last year, in October, I had between four and five hundred cuttings put in from roses grown in pots, consisting of some of the best new sorts. About twelve cuttings were put in each pot, and the pots were placed in a frame, where they have continued all through the winter. They are all now thoroughly rooted, and want planting out the first opportunity. I have frequently struck great batches of the Fellenberg Noisette and Céline Forestier for planting in hedges, and all on a south border in the open air. The Fellenberg is one of the very best of perpetual flowering, dark-coloured Noisettes, and when mixed with Céline Forestier a hedge of them is grand all the summer and autumn, the only drawback being that severe winters often cut them down; but they spring again from the roots. Roses on their own roots ought to be planted more than they are; for, either as bushes or pillars, they are far more graceful than the cabbage-headed standard roses now so much patronised. Another reason for cultivating roses on their own roots is their safety in very severe winters; for, if cut down to the ground or snow line, they will spring up again from the roots, and soon show their former beauty. In cycles of ten or twelve years a killing frost thins all the standard roses, and both nurserymen and gardeners suffer great losses in their collections. For exhibition purposes, perhaps, the largest and finest specimens of rose flowers are grown on standards, the first or second year after budding; but, for a display of the Queen of Flowers, give me a pillar rose tree covered with flowers from ground to top.—WILLIAM TILLERY, Welbeck.

— Is "G. S." who feels disappointed with "Y." in not letting him know the way in which he grows his cheap roses, will try the following plan, he will doubtless be able to grow them by the hundred or thousand. I select my cuttings in September or October, and put them in any odd corner of the garden. The cuttings have about six eyes, three below and three above ground. I make a trench to begin with, as if I were going to put in box edging, put in the cuttings, tread them firmly, and then level for the next trench, and so I go on until all are in. I put in two hundred cuttings last October, and of these only two have missed growing. Those I inserted the season before made shoots four feet and five feet long. I have struck Devoniensis most successfully in this way.—W. J.

— "Y.'S" METHOD of managing rose cuttings, which is so mysteriously held back, is doubtless striking them in water. Cuttings put in a glass of water in a warm room will grow—i.e., make roots. A lady whom I know strikes quantities in this way. They, however, require very careful handling afterwards, in the matter of potting, &c. The roots, being so tender, damp off in the soil—a circumstance owing, doubtless, to the bruising they receive by that operation. The varieties which will most readily grow in this way are the Teas; the most success attended the trial of other varieties when small fine cuttings have been used. Now the pruning time is come, plenty of opportunities will offer for the experiment.—HENRY MILLS.

— I sometimes strike a few Roses, not by the thousand, like "Y.", but ninety-five out of every hundred cuttings put in can be struck in the following manner:—In the spring, as soon as the roses have made shoots about six inches long, I take a sharp knife, and where I think them too thick I take off some of the young shoots with a bit of a heel to them. I then have some six-inch pots ready, with plenty of drainage in them, and fill them with soil consisting of loam and leaf-mould, with plenty of silver sand. I put ten in a pot, and then plunge them in the cutting-frame, with a bottom heat of about 75°. I shade them as little as possible, give them plenty of air, plenty of heat, and plenty of moisture; and thus managed they strike as freely as Verbenas. There is no secret in that. I have some plants in frames now that were struck last May. They consist of Madame Margotin, Céline Forestier, Charles Lefèbvre, and Elizabeth Vigneron, all of which are, of course, small; but nevertheless they have on them three or four blooms each, and I find them handy for the decoration of small vases in the drawing-room or for cutting from; if they are spoilt, it is of no importance, as I can strike more next May. On the 17th instant, I planted out twenty Maréchal Niel and about a hundred Hybrid Perpetuals of kinds that were struck at the same time and had been kept in pots in a cold frame. They are from twenty to thirty inches high. I shall cut them down nearly close to the ground, and take all shoots off but the two strongest, and next year they will be pegged down to make an edging for the centre walk in the kitchen garden.—J. PINK, *Lees Court*.

— ONE of the largest rose growers in France says:—My principal propagator employs two methods for striking rose cuttings. 1st. He keeps strong plants of each sort of roses we have in large pots, which are plunged in a bed of ashes. About Christmas, when he looks over his stock of roses on their own roots, and finds that some sorts have run short, he removes the rose trees of the said sorts which are in pots into the propagating house, where they soon push young shoots. About the end of February he cuts all the young wood off, divides it into bits with two buds each, and plants the cuttings closely in silver sand in frames, which are on both sides of the propagating house, and under which the flue runs. The frames are two feet broad, and are covered with movable panes of glass, which are washed every morning. My propagator takes great care in inserting the cuttings, to cover only the lower bud. After they are planted, they are watered through a finely rosed watering-pot. In three or four weeks all will have struck root. They are then potted off into small pots, covered again for a week or two, and then removed to an outside frame, where they get hardened off.

The second method is, in the beginning of July, to take the half-ripe wood of such rose trees as my propagator wishes to increase, and to cut it in the same way as has just been described; but, instead of planting the cuttings in the propagating house in heat, he inserts them in frames against a north wall, which he has nearly filled with finely-sifted coal ashes. In about five weeks all will have struck root, and none will have damped off.—G. S., Cheltenham.

[Other interesting communications on this subject remain over till next week.]

THE ROSE GARDEN FOR MARCH.

BY GEORGE PAUL.

ROSES are now in so forward a state as to almost necessitate immediate pruning in order to have dormant eyes to prune back to. The present time is considered, I believe, by amateurs early for the operation; but, from considerable experience (last year's especially on a very large scale), I think pruning should be done earlier in the season than it is in general. The fact is, we are losing in our Hybrid Perpetual roses the character retained from the damasks and Hybrid Bourbons, and getting the earlier growing and early flowering habits of the Chinas. Of course, the numerous seedlings of General Jacqueminot, a host in themselves, have led to this organic change. The season will somewhat modify the pruning. One must prune back closer than ordinary to have a good unshot eye to start with. Thin the shoots well out, leaving no wood in the head that is not healthy and fairly vigorous. Study the individual habits of the roses; the catalogue descriptions of vigorous, robust, and moderate being in some sense guides. For instance, Maréchal Vaillant, a vigorous kind, does not bloom if cut in close. Its shoots require to be left at least one foot to one and a half foot in length. Robust roses, as Madame Vidot or Baroness Rothschild, with short stumpy wood, should be pruned to a prominent bold eye—the best on the shoot, high or low. The small wood of these sorts never yields blooms worth having, and must be cut clean out. Moderate roses, as Mlle. Bonnaire or Xavier Olibo, need close pruning. They may be cut in almost to the old wood.

quite so, when the shoots are weak. The eye to which the shoot is pruned should, if possible, look outwards. If this rule is followed, a hollow head will be formed, allowing air to circulate well amongst the foliage and flowers. Prune, if possible, after a day's drying weather, as, if the ground is in good order, roses do not bleed badly. Choose likewise fine weather to dig the ground, turning in some manure, unless this has been already done, when a mulching of some short horse dung (road droppings, fermented by having been in a heap, are good for them) may be applied early in April.

Make good all vacancies in borders where the kinds to be planted are Hybrid Perpetuals, Noisettes, and standards of the Teas, and reserve places for dwarfs of Tea roses, which are better planted from pots in May.

In the forcing houses a few kinds started in November will be just opening, Souvenir d'un Ami, Madame Falot, and the white Hybrid Perpetual Marquise de Montemart, are amongst the first. Where plants are just breaking syringes twice a day, which will also supply almost sufficient moisture to the plants; 55° to 60° is a good day temperature, which may fall to about 50° at night. All pot roses should now be pruned, as after May, grown under glass, they do not compare favourably with the early flowers from out of doors. It is well therefore to get all pot roses over by the end of that month. Pot roses should always be pruned some days before being started, however slowly, into growth.

EARLY SPRING FLOWERS.

A LOVE for flowers of all kinds seems naturally implanted in man; but it is the early flowers of spring that always bring along with them the greatest degree of pleasure. Our affections seem immediately to expand at the sight of the first opening blossom under some sunny bank, however humble its race may be. Addison says that he always looked upon the whole country, in spring-time, as a spacious garden. We then welcome our long-lost associates with a cordiality that no other season can excite; and Flora, even early in the year, scatters her gifts all over the land with generous hand—some to deck the valleys with innumerable hues, others to adorn our upland pastures. Who among us has not admired the drooping Snowdrop of peerless white, or the pale Primrose, which garnishes the hedgerow bank, or the Wallflower, whose abode is everywhere, from the crumbling ruins of the dismantled abbey to the humble cottager's garden, or the meek Violet, whose home is in the secluded dell, where at dewy eve its fragrant sweets are tossed upon the gentle breeze? These, when they reappear in spring, stir up dormant memories which few can altogether abolish. The sight of the Crocus bursting through the mould bespeaks the advent of sunny days. With summer flowers we seem to live, as with our neighbours, in harmony and goodwill, but for early flowers we cherish a private friendship; and, when we first meet them in spring, it is like meeting with a long-lost friend. Autumn Violets are greeted with none of that affection with which we hail Violets in the spring; they are unseasonable, and we view them with curiosity rather than delight. The last Rose of autumn loses its charm compared with the first Rose of summer. Every season, however, has its peculiar charms, and autumn's sere and yellow leaf yields to many as much enjoyment as the full gush of young foliage in spring.

Amongst the earliest flowers of the year are those of the Christmas Rose and the fragrant Coltsfoot, whose beautiful blossoms load the air with perfume. The vernal Hound's Tongue, too, rivals the Forget-me-Not in loveliness, and, like the Primrose, is a "lorn tenant of the peaceful glade." The Wood Anemone carpets the shady grove, and Hepaticas of various hues also love the shade and thrive best when undisturbed. The humble winter Aconite, with golden flowers frilled with green, must also be classed amongst the first harbingers of spring; as must also the vernal Pheasant's Eye, with golden flowers prettily set off with leaves like Fennel. The charming little Moor Heath (*Erica carnea*) is indispensable to the spring garden, giving it a warm, wild, rosy glow, much wanted on a cold spring day; and not less valuable is the Mezereon, whose branches, though leafless, are well attired and thickly beset with blushing floral wreaths. With these may be associated the Poppy Anemone, concerning which the poet exclaims,

"See you Anemones their leaves unfold,
With rubies flaming and with living gold;"

and Dog's Tooth Violet, of humble growth, with spotted leaves and drooping flowers; also our beautiful little early Squills, with flowers of celestial blue; or the Blue Bell, with its spikes of nodding bells, which deck the woods and groves in imperial hues. Nor must we omit the Crown Imperial, or the bold Daffodil that defies the winds and storms that sometimes beset it early in the year. With materials such as these there need be no necessity for bare borders or beds in spring.

GEORGE GORDON, A.L.S.

THE FLOWER GARDEN FOR MARCH.

BY GEORGE WESTLAND, WITLEY COURT.

WHERE new lawns have to be formed, the preparation of the ground is of the greatest importance, and except this is attended to in the first place no after management is likely to be so thoroughly productive of that verdant close, even, evergreen turf so desirable; and unless good turf can be secured, perfectly free from coarse grasses and weeds of every description, I would favour sowing with seeds adapted for the formation of a permanent lawn, being particular that the ground is made evenly solid. Lawns that were top-dressed early in winter, and such as are patchy, will be improved by being sown with grass seeds and white Dutch clover; afterwards rake and roll over the ground. Finish turfing repairs, and edge the margins of walks. This is a good time, before the ground becomes hard, to grub up Daisies, Dandelions, &c. Sweep and roll turf; the rolling should be done the day previous to mowing, and lose no time in having the grass cut with the machine, which will greatly improve the appearance and texture of the turf. Specimen ornamental shrubs should now be pruned. Azaleas, Hollies, Bays, Portugal Laurels, &c., will be greatly improved by going over them with the knife, so as not to lacerate the foliage. The branches may also be regulated; cutting back straggling shoots upon such plants as Junipers, Retinosporas, Yews, and Thujas, &c. Unless such plants as the Irish Yew, for instance, are rendered compact by pruning, they break down and often become unsightly. Borders containing herbaceous plants should be manured and dug; and such plants as require it should be divided and replanted. Herbaceous plants are the first to cheer us in spring and the last in autumn; they therefore deserve a little attention. Towards the end of the month, plant Gladioli either in groups, beds, or lines, keeping the crowns about three inches under the surface. That soil is best for them that has been enriched with manure twelve months previously and frequently turned; avoid manure in any form coming in contact with the bulbs, as it is almost sure to generate decay although it gives continuity of bloom. Gladioli should be planted at different times. They are also well adapted for pot culture. Mignonette may now be sown, and after the middle of the month sow hardy annuals at intervals. Transplant autumn sown annuals, and thin out those remaining, so as to induce perfect development. Sweet Peas should now be sown.

The following is a list of good Bedding Pelargoniums; but it must be observed that soil, situation, and other local circumstances often effect such a decided change in certain kinds, that it is impossible to say whether or not they will be equally effective everywhere. They have been, however, all that could be desired here.

SCARLET.

Vesuvius, first-class in every respect.

Waltham Seedling, fine bedder, the finest in the Stella section.

Lady Constance Grosvenor, a remarkably bright and effective variety—one of the best.

Bayard, very dark crimson; very effective.

Violet Hill, very dwarf; requires liberal treatment; first rate when well grown.

Tom Thumb, still one of the best for effect when planted in large masses, and good in all seasons.

Warrior, a veritable scarlet, with fine trusses of bloom; for large beds and vases this is a most effective kind.

Duchess of Sutherland.

PINK.

Christine, still the best; Blue Bell, a fine variety.

WHITE.

Madame Vaucher, than this we have yet nothing better.

Purity, also a good bedder.

Waltham Bride and Avalanche, two silver-edged kinds, with white flowers; both charming and very effective.

GOLDEN TRICOLORS.

Sophia Dumaresque, Sophia Cusack, and Lady Cullum. These are inferior to the Golden Bicolor kinds, with plain yellow leaves, which are best adapted for effect. Such as Crystal Palace Gem, a desirable variety of fine habit and constitution, Golden Chain, and Golden Fleece, may also be grown as the best of that section.

SILVER BICOLORS.

May Queen, one of the most effective, with pure white and green leaves; Flower of Spring; Mangles's Variegated, still a very useful trailing variety.

Pits and Frames.—Push forward propagation with the utmost dispatch, maintaining a brisk heat; and be careful that soils are properly prepared and aerated, as much mischief is done by pottng tender cuttings in cold, wet, pasty soils. Never allow a plant to experience a check if possible. Prick off seedlings as soon as they are fit to handle; and remember that if they are allowed to become

drawn and leggy in the seed-pans, no after management will insure such a perfect plant. Secure a good stock of Coleus Verschaffeltii and Batemanii, which are the two finest varieties of that genus for bedding purposes. Also Iresine Lindenii and Herbstii, both of which rank amongst the most useful plants we possess. Do not overlook Ageratum imperial dwarf, so serviceable among blues and more effective even than Lobelia at a distance. Divide and pot herbaceous Lobelias. Pot off cuttings and remove the more hardy among them to cold frames, to make room for the raising of the tender kinds of seeds, which should now be sown in well-drained pans in light, sandy soil.

THE FRUIT GARDEN.

THE DYEHOUSE CHERRY TREE.

About thirty years ago, an old man named Dychouse found growing in his orchard, among some English Morellas, a small bushy tree, which differed in form from the others, and also ripened its fruit some four weeks in advance of them. The fruit was about the size

The Dyehouse Cherry Tree.

of that of the Morello, but different in colour and shape; and the tree was found to be much harder than its supposed parent. It grew vigorously, and soon became a good bearer. The original tree is now dead, but others raised from it have been disseminated to a limited

The Dyehouse Cherry.

extent over this (Lincoln) and a few adjoining counties. The raiser was not a fruit-grower. He lived out in our hill country, far removed from fruit regions, and no one, until recently, except a few neighbours, knew anything of this cherry. Eight years ago I planted fifty plants of it, about five feet high and with stems an inch in diameter;

they grew rapidly, and for the past four years I have gathered full crops from them. They have been in full bearing for three years, and have not wholly failed, even this present year (1871), when all other fruits, without exception, were totally destroyed by the severe cold of April 29th. I believe this variety to be a seedling. It is certainly very desirable. As a fruit for tarts and preserves, it has no competitor in the cherry kingdom. The fruit is quite tart, but when fully ripe is, to my taste, perfectly delicious, having the most pleasant and agreeable acid. This cherry would make a fine wind-break and ornamental hedge, if planted eight feet apart, and cut down at planting time to within a foot of the ground, and annually pruned. It will bear much cutting, with impunity. I saw a small orchard of it, which had been repeatedly browsed by stock, and it grew finely. I cut one down to the ground, and it threw up a dozen vigorous stems, and grew into a beautiful bushy tree.—*American Agriculturist.*

JANUARY'S TEACHING.—FRUIT TREES.

At first view it may appear somewhat remarkable that fruit trees should be so little influenced by eight weeks of weather more or less mild, moist, and unseasonable. Spring flowers are expanding, and spring plants are making rapid growth, so that we have already a garden chequered by bright blossoms, those of early rhododendrons being conspicuous; but the apricot, which is especially susceptible of abnormal warmth in the early part of the year, is almost quiescent. Peach-buds are scarcely moving; and pears, considering the many temptations offered by a spring-like temperature, betray the same commendable reluctance to burst into bloom. Early plum-buds exhibit a disposition to expand, but are by no means so far advanced as to be liable to injury from frost.

We may learn, from the occurrence of a season such as we are experiencing, that circumstances may exist which tend to modify the effect of temperature on fruit-trees. It seems that dull and cloudy weather, even when accompanied by a vegetating temperature, is insufficient to excite deeply-rooting trees. When the weather is frosty, but clear, apricot trees are more prone to open their blossoms. Perhaps it is not alone the hygrometrical condition of the atmosphere that has kept fruit trees inactive. The soil was chilled by severe frost in December, and frequent falls of rain throughout January surcharged the land with wet, and so rendered it impervious to the influence of the milder condition of the air.

The lesson taught us by the circumstances I have attempted to describe seems to me to be capable of application in the management of wall trees, which are often excited by bright weather early in the year, and are, as a rule, cut off by succeeding frost. It is to exclude the trees, by covering them early in the year, from the existing influence of bright sunlight, and by watering the borders abundantly, or otherwise procuring such a state of things as exist to depress the temperature of the ground at this season, so that the roots may be kept from the stimulating effect of early but treacherous warmth.

An examination of our weather record for January shows but little variation of temperature, the range being only 26°, and an absence of severe frost, unusual in the first month of the year. The lowest reading of the maximum thermometer was 39° on the 20th; a temperature of 52° was recorded on the 4th, and 53° on the 30th; the average maximum temperature of the month was a little short of 47°. The minimum thermometer recorded slight frost on eight nights, the lowest reading being 27°, or 5° below freezing, on the 15th. The occurrence of clear sky and unobscured sunlight was recorded on eight days only; so that there were twenty-three dull and cloudy days; a south-west wind prevailed, and rain was registered on eighteen days—the amount collected was about three inches (2.97 actually). The same dull, moist weather has characterised the month of February up to the present time (February 15th); a change of wind from south-west to east and north-east somewhat lowered the temperature of the air.

Belvoir.

W.M. INGRAM.

THE FRUIT GARDEN FOR MARCH.

BY WILLIAM TILLERY, WELBECK.

Outdoor Fruits.—March, the most uncertain month in the year, makes it necessary to devote more attention than most gardeners can give to preserve their fruit blossoms from its scathing power. The month this year is likely to have a great preponderance of easterly winds, for the prevailing currents have been southerly for the last two months, and there is almost sure to be a reaction. Up till this date in February, rain has fallen more or less on nearly every day, and the soil is quite saturated; but a change to slight frosts in the mornings has taken place, and the air is gradually getting drier. Apricots, peaches, and nectarines will want protection as soon as the

blossoms show colour. Glass coverings are certainly cheapest and best where they can be had, and strong canvas the next where it can be rolled up and down, according to the weather. All nailing and pruning should be completed as early in the month as possible, for the blossom-buds of hardy fruit trees on the walls are swelling fast. I find pears on the quince stock to be more advanced in their buds than those on the pear stock. The time for grafting will be earlier in March this year than usual, and grafts intended for using must be placed in the ground behind a north wall till wanted. There are often many worthless kinds of apples and pears in collections, and the best way is to cut their heads off and graft them with good sorts. Gooseberry and currant bushes will soon have their foliage expanded, unless a check comes soon, and protection of some kind may save a crop should there be severe spring frosts. Fern leaves, dry hay, or fir branches, will if put on the top of the bushes on the appearance of a severe night's frost often afford sufficient protection. Strawberry plantations will now want dressing, and if a slight covering of littery manure is spread over the beds the foliage will grow through it, as well as the flower stalks, and the straw will keep the fruit clean.

Orchard House Fruit Trees.—The mild season has naturally brought all kinds of fruit trees grown in pots into bloom sooner than usual. If the pots have not been top dressed in the autumn they should now be done so by making a rim of fresh cut turf round the edges of the pots with the grassy side down and filling the centre with some well rotted cow or sheep dung. This will give fresh vigour to pot trees which have not been repotted for years. Before the flowering process commences, syringe with Gishurst Compound of the strength of three ounces in a gallon of water, and this will help to keep the trees free from mildew and aphid; soft soap dissolved in water of the same strength is likewise an excellent corrective of mildew on Peach, Nectarine, and Cherry trees.

Vineries.—As soon as the stoning process in the earliest viney commences, a steady night and day temperature must be maintained. The thinning and stopping the shoots in the succession houses will want frequent attention; and muscats, when in flower, require a high temperature, 70° not being too high. To have this fine variety of grape in the greatest perfection as regards colour and flavour, the forcing of it should be commenced in January or February if possible.

Peach Houses.—The thinning the fruit where too thick, and tying the shoots down as they advance in growth, must be attended to. In the earliest peach house it is better to leave the fruit rather thick on the tree till the stoning process is over, as some may drop off then. The temperature must be kept rather lower and equable till the stoning is over, and the inside borders kept well watered. The dull, sunless weather of the last few weeks has been against peaches and nectarines setting well in the late succession houses without artificial fertilisation.

Fig House.—Figs, whether grown in the borders, tubs, or pots, will now require liberal waterings and syringings over head on fine clear days. Some liquid manure may likewise be given them occasionally until they begin to ripen. The most luscious figs I have ever tasted were grown in pots, and the trees placed on bricks on the flue of a succession pine pit. The sorts were the White Marseilles and Lee's Perpetual, and the fruits, when ripe, were of the most delicious syrupy flavour. The trees were grown in turfy loam brought from the top of a limestone rock, and the pots when placed on the top of the flue had the trees well rooted in the soil. The pots were placed in shallow pans containing water and liquid manure, until the fruit began to ripen, when the watering was discontinued for a time.

Cherry House.—Cherries require to be kept in rather a low temperature when stoning; from 50° to 55° will suit them. Air must be given freely in favourable weather.

Cucumber and Melon House or Pit.—The weather lately has been much against the growth of young Cucumber and Melon plants, for the long continuance of dull days and want of sunshine have given them a sickly appearance, and many of the earliest raised plants have succumbed. If grown in dung beds the linings must be attended to, so as to keep up the requisite temperature. When grown in houses or pits heated with hot water, the trouble of growing them is greatly lessened, for heat and moisture can be better regulated there. Sow now good batches of seeds for succession crops, and keep the young plants in the seed beds till strong enough to hardened off.

Strawberries.—The earliest placed plants in heat will now begin to show colour, and watering must be more sparingly given to improve the flavour. The Black Prince with me is now beginning to ripen, but I shall discard it in another year for forcing early, for it is only a small fruit with not much flavour, and the plants are very

liable to mildew. Keens' Seedling is, if from selected plants, perhaps, the best early forcing strawberry yet grown, and President is also very good for a second kind for succession.

THE PINERY FOR MARCH.

BY JAMES BARNES.

PAY great attention to fruit swelling in all stages; continue to allow an increase of heat by day and night, as the light increases. Maintain a kindly humidity, taking care to ventilate, but so as to avoid draught. Give tepid, clear manure water to the roots, and syringe round the stems and over the plunging materials with the same. Some charcoal laid about the surface of the plunging material is also beneficial in absorbing and giving off gases and humidity. Take care that such fruits as have nearly finished swelling get neither bottom watering nor syringing about the stems; and if they can be moved to a light, dry situation, let it be done, in order to improve colour and flavour, and make room for others that may be starting. From those now in bloom withhold syringing for a short time till they set, and apply but moderate humidity. Give such pines as are now starting into fruit every encouragement, in order that they may make a bold and strong appearance; taking care at the same time not to stint them for water at the roots. Select for another batch the finest, fittest, ripe, well-grown plants, and place them together on a well-prepared, moderate bottom heat, to come into fruit in succession, and shift on other successions to replace them. In the case of succession plants, there must be no stand-still; shift them on as they require it into good sized, well-drained pots, in which they are intended to fruit, using good, healthy, sweet, well-pulverised soil, charcoal, and soot. Place them on a kindly, moderate bottom heat, increasing the atmospheric heat as light increases, which will also naturally raise the bottom heat a little. Syringe freely now on fine afternoons, shutting up early. Maintain a kindly, humid growing heat, and allow the plants to make full speed while there is light and heat. No check must be allowed, or splendid, well-swelled fruit will not follow in succession at all seasons of the year. Starve or stagnate a young pine-plant, and it will never produce perfect fruit. Suckers, take off in succession as you clear away the fruit, and pot and start them immediately. Thus fine plants and noble, well-swelled fruit will be the result. Push them along at full speed on a kindly, healthy bottom heat in a humid atmosphere, well charged with ammonia, giving kindly methodical syringings early on fine afternoons, airing freely in order to fully maintain robustness and vigour throughout their progress, and never allowing a plant to get dry at the root, or pot-bound for lack of timely re-potting. Attention to little items like those cannot fail to end in complete success.

WHAT THE DATE TREE IS TO THE SAHARIANS.

THERE are eight villages in the oasis of Wodian, in the Desert of Sahara. The chief occupation of the inhabitants is the cultivation of the date tree. At Kreez one of the villages, there is an excellent spring of water; but it will not supply all the plantations. Therefore deep wells have been made, and by the aid of camels the water is raised from them in earthen jars whose contents are emptied into wooden troughs. The water is conducted by long trenches into channels, which, when one plantation is well watered, is diverted to another grove of trees. The blessings of the date palm are never-ending to the dwellers in the Desert. First, it delights the eye by its picturesque appearance; it affords shade, without which the heat of the sun would be beyond endurance; its fruit is food; its wood is fuel; houses are built of it; and from its leaves baskets, ropes, mats, bags, brushes, brooms, beds, and fans are manufactured. From its branches the natives make cages, fences, and chairs. After the kernels of the fruit have been soaked two or three days in water, camels will eat them with eagerness.

The date tree reaches its highest vigour at thirty years, and continues bearing fruit in perfection until it has reached its one hundredth year. It gradually decays for a hundred years more, and then dies. A date palm yields during its best years between twenty and thirty clusters of dates, each cluster weighing about thirty pounds. If the suckers, of which every date tree throws out a number, are removed and transplanted, fruit can be obtained from them in ten years' time. Trees raised from seed will not yield dates until twenty years old. The Arabs love their palm trees. They would not leave the desert with its groves of dates for the Garden of Eden.—*Hearth and Home.*

Extreme Cold.—A rural American paper says they have no thermometer in their town, so the weather gets as cold as it likes. Another journal of western New York reports the glass “30° below nothing, and it would have gone much lower, only it wasn't long enough.”

COLOCASIA ODORATA.

For warm conservatories, large stoves, &c., this is one of the most imposing and easily grown of fine foliaged plants. It is indeed so easy of culture in a warm structure that by merely planting it out in a bed of loam, or even in a gravel pathway, it grows without any further trouble. It is a native of the East Indies, and its stems are usually from three to eight feet in height, but when planted out in warm stoves it will even attain greater dimensions. When well grown the leaves measure more than three feet in length, are very handsome, and of a fine fresh green colour. The flowers are comparatively small for such a large plant, of a pale greenish yellow colour, and delightfully fragrant. As they open one by one in spring they do not attract the eye, but quite fill the air with a delicate odour. This is one of the plants used in the open air in summer for the sake of its fine foliage; but it does not grow so well as Caladium esculentum in the open air. It endures the open air in summer in the neighbourhood of Paris, and also in the warmer parts of southern England, but should not be planted out till June. Its chief attraction for the sub-tropical garden, as distinguished from other large plants of the Arum tribe, lies in its somewhat tall woody stems; the other kinds are almost stemless, or have only very short stems. It is quite easily propagated by division, or, in some cases, by means of pieces of the stem.

PLANTS FOR A NORTH HOUSE.

If the light is much obstructed, ferns and Selaginellas will give the greatest amount of unmixed pleasure with the least cost. But if nothing obstructs the light, many things may be grown as well in a north house as in any other aspect, especially in summer. I am assuming the house is heated in some way or other. In a mixed collection, where there is only one house, it is not desirable to attempt growing many hard-wooded plants, and those should all be of very easy cultivation.

For winter and spring blooming grow the following:—Dutch bulbs, potted in October, placed in the open air, and covered over with six inches of ashes, old tan, or coco fibre, till the pots are filled with roots (about six or eight weeks); Lily of the Valley will bloom late, but will be none the less beautiful; cineraria, sown twice, first in April and again in July, potted off, and grown in a cold frame, or on the north side of a fence or wall, to be housed before frost comes; Solanum capsicastrum (hybrids), sown early in spring, potted off, and planted in a rich border in June, to be lifted and potted in September, will brighten up the house with scarlet berries all the winter; Cytisus racemosus; camellias; violets (Neapolitan, Giant, and several double sorts); mignonette, sown in pots in July and August; several annuals, sown in September, such as Saponaria calabrica, Nemophilas, &c.; musk is a favourite pot plant in large cities; Lycopodium dentifolium; myrtles; a plant or two of the fan palm (*Chamaerops humilis*); Dracaena australis; Cyperus alternifolius; Abutilon Thompsonii; several acacias, such as armata and Drummondii; Calla ethiopica, Primula sinensis, &c.

For summer: calceolarias, sown in July, and the seed pot plunged in ashes under a hand-light, and shaded, when up pot off, and grow in a frame under a north wall, to be taken in before winter. These will flower beautifully in a north house in June and July. Fuchsias will do well in summer, and may be placed under the stage in winter.

Zonal geraniums; lilies, especially the lancifolium section, and auratum. A few chrysanthemums may be grown out of doors for blooming in October and November. Several of the variegated Japanese plants of recent introduction would be useful in winter, when flowers are scarce, but in houses of this kind do not crowd them too much. It is better to grow a few plants, and do them well, than to fill the house too full. Damp is the chief thing to guard against in winter; but do not aim at too high a temperature, and ventilate as freely as possible when the weather is favourable.

E. HOB DAY.

Ramsey Abbey.

VENTILATION DURING WINTER AND SPRING.

WHATEVER views are held, or system adopted, in regard to ventilation, our practice must be modified, or at least ought to be, by times and seasons. For instance, many years' practice has convinced me that, unless for any special purposes and under exceptional conditions, all through ventilation should cease from December to April. Of course I am writing of houses in which a high temperature is maintained, such as plant stoves, intermediate plant houses, early vineries, peach houses, &c.

In winter and early spring ventilation, the primary object should be to renew the atmosphere without creating draughts. The

regulation of temperature is a less important matter. I say this advisedly, knowing that many may think otherwise. But a rise of ten or fifteen degrees caused by the heat of the sun does no injury. And if it did, the injury would be nothing compared with that caused by keeping down the temperature to its proper level by means of a current of outside air passing through the house. Many hardly believe in ventilation at all, unless they feel a rush of air passing through, or at least have the opposite sets of ventilators open simultaneously. In the early months of the year, we ought not to be able to feel the movement of the air. If we do, it should be a warning that the ventilation is injuriously excessive. Air circulates freely enough with only one set of

Colocasia odorata.

ventilators open. It is astonishing how subtle heated air is, and how soon it finds an exit, even if that is at the lower part of the house. This is easily proved by introducing a few dishes of hot water, or burning a little paper or tobacco in a hothouse at work. The steam or smoke will point out the course of the air as it travels with it in a visible form. The top ventilators establish a double current at once, but it takes a little longer for air to find its way out and in at the lower openings. In this way the air of a house gets changed thoroughly without creating draughts. True, the change is more gradual, but this is the chief merit of ventilation early in the season. Hurried ventilation is most mischievous. We want to let out exhausted and to let in fresh, unused air; the danger lies in a too rapid exchange; and in doing it, our chief object is to let out and in no more than is needful, for all excess in either direction involves a loss of heat and of moisture. The air let in is colder and drier than that let out. The first thing this newly-admitted air does is to warm itself and quench its thirst at our expense. This may seem a small matter to some. Water is plentiful, it may be, and there is no stint of coal. It is, however, a very serious affair to the plants, for the cold air does not take the trouble to go and hug our pipes round till it gets warm, nor to run to our cisterns and evaporating pans to wash itself clean and mollify its harsh, biting thirst. On the contrary, it steals heat and extracts water from every tender leaf and flower it touches, and makes them shiver and starve under

its exactions. Hence the more cool air passed over them the more they loose, and the less they have left for themselves. Therefore, unless the air can be both watered and warmed before it enters hot-houses in winter and early spring, the loss of it that sweeps through them the better. Neither is there any necessity for ruches of cold air through hothouses. A change of air is, undoubtedly, desirable; but even the importance of this has been exaggerated. Air is not so readily exhausted by plants as many have assumed, and there are few or no glasshouses so closely constructed as to be air-proof. In almost all of them an interchange is taking place between the internal and external air, and the circulation of the internal atmosphere is incessant. Apart from any exchange between the heat of the pipes on the one hand, and the coldness of the glass on the other, the air has a restless time of it.

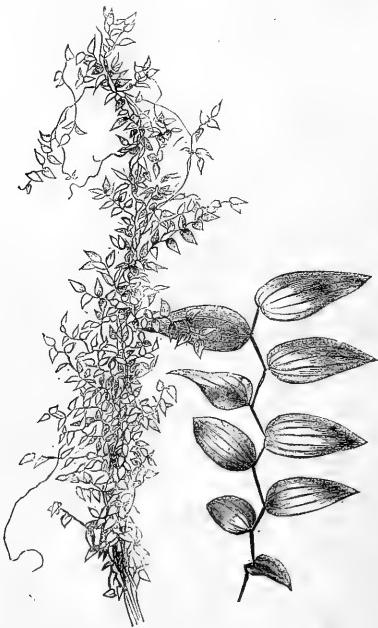

I must not, however, be understood as decrying ventilation; on the contrary, I am simply advocating caution. Either set of ventilators may be opened alternately; but, during the winter and early spring, it is best not to open both simultaneously, unless the outside and inside temperatures approximate to equality.

D. T. F.

THE CREEPING MYRTLE.

(MYRSIPHYLLUM ASPARAGOIDES.)

For some years the florists around Boston have cultivated a charming greenhouse evergreen, which is extensively used in floral decorations. We first met with it a few years ago in the hands of a New York florist, who knew it only as Boston smilax, and it is by some called Boston vine. The name Myrsiphyllum means Myrtle leaf, and asparagooides, resembling

The Creeping Myrtle.

asparagus, a likeness which, while it is apparent to the botanist, is not very manifest at first sight. The roots are fleshy; the stems, though small, are strong and elastic, and climb to the height of some twenty feet. The foliage is of a fresh, lively, shining green. The flowers are small and white, appearing two or three together, and are followed by a globular berry. The plant is grown in ordinary greenhouse culture, and is trained upon strings. It will grow well in rooms, especially if

it can have an abundance of light, and when trained over a support of some kind soon covers it with luxuriant green. It may be propagated by dividing the root, but our florists generally raise it from the seed, which is freely produced by old plants. This matures in July, and is sown as soon as ripe. It is a native of the Cape of Good Hope. The engraving gives some reduced branches and a portion of the plant of the natural size. The delicacy and beauty of the myrsiphyllum especially adapt it for use in floral decorations, and it has an additional good quality—it lasts a long time in good condition when cut. For making up floral wreaths for the hair it is superior to all other green, and large quantities are used for this purpose alone. It is sometimes used with fine effect to trim a white dress; being obtainable in long pieces it readily forms a graceful tracery far superior to any embroidery. We think that the cultivation of this plant for ornamental purposes must be peculiar to this country, as we do not find it in any of the European plant catalogues, or in foreign works on floriculture. Latterly the florists near New York have engaged in the culture of this plant, some of them devoting whole houses entirely to it. The myrsiphyllum bears cutting well, as new shoots spring up in great abundance after each cutting back. [The above charming plant, the figure and description of which we borrow from the *American Agriculturist*, is occasionally seen in botanical and curious collections in this country. In America it is now the most important plant for adding grace and verve to floral decorations. It is usually trained on strings of twine, led from each small pot to the roof. Each plant forms a beautiful glistening wreath around its string. By cutting this the wreath is easily carried, and may be used without disturbance in many kinds of indoor decoration.]

THE INDOOR GARDEN FOR MARCH.

BY T. BAINES, SOUTHGATE.

Conservatory.—The materials for keeping up an effective display in conservatories will now have become more plentiful than during winter, and one of the most important considerations is, to see that portions of such things as will bear retarding without injury are at once placed under conditions to insure their being made available later in the season. Where, indeed, anything like a continuous supply of blooming plants is required, it is quite necessary to have at command a house so placed that the sun will have little influence upon it, except for an hour or two morning and evening. A lean-to with a north aspect is best. Many imagine that such houses are only required by those who retard plants for purposes of exhibition; this is a mistake. By selecting a portion of the stock of Camellias, Azaleas, Epacries, Geraniums, Cinerarias, Cyclamens—in fact, any of the numerous greenhouse plants that are used for conservatory decoration, the blooming season may be prolonged to almost double its usual length, especially if judgment is used in selecting varieties that are naturally late in flowering. Camellias—candidissima, fine white; Bealii, red; Lavinia Maggi, striped;—Azaleas—brilliant and Julianæ, both red; Extrani and corona, both bright rose; Glestanusii formosa, white striped;—Epacries—eclipse, grandiflora, rubra, and miniata splendens. These, and others, which the careful observer cannot fail to note, can be retarded without injury, so as to come in at a time when they will be found of great use. And it is not only during spring when such a house will be found of the greatest value; it will also be an excellent place in which to harden the stock of Ghent Azaleas, double flowering Plums, Lilacs, Spiraea, &c., that have been forced, and which frequently, from want of a suitable place, are subjected to treatment ill calculated to render them of use the following season. Later in the season, too, it will suit Camellias well that have set their bloom, and which, from want of proper accommodation, are turned out of doors; further on in the season still, late flowering Chrysanthemums may be kept safely in such a house until the middle of January, at which time they will be found most useful. Large Camellias, which have got leggy from want of judicious pruning when young, or through overcrowding, may be improved in the following manner.—Take, at once, a couple of healthy young plants, in six-inch pots of any approved kind, place these on the surface of the ball of the plant to be operated upon; then inarch the heads of each of the young plants as low down as they can be got on the opposite sides of the large plant. These will become firmly united during the summer, when they may be severed from their original stems; and in the following season, before growth commences, the head of the stock or naked plant may be cut away just above where the young plants have been

inarched, when they will commence to grow apace and in a little time make a handsome plant. Movable shading, of thin material, should be got ready, as bright sunshine on a March day makes short work of many things in flower. Pinch out the points of a portion of the stock of Pelargoniums. These will be useful in July, after the early ones are over. Start another batch of Achimenes, Gloxinias, and Tydas for summer decoration. See that Lilies, breaking through the soil, are not left where they have an insufficiency of light; otherwise they make weak growth, which no care afterwards will put right.

Stove.—Finish potting the principal hard-wooded occupants of stoves as early as possible. Alocasia Veitchii and Lowii are plants which are frequently not well grown, chiefly through being potted in unsuitable soil. They do not like anything of an adhesive nature; they do best in one-half fibrous peat, one-half chopped sphagnum, with a liberal admixture of sand. Alocasia metallica enjoys the same materials. The more easily grown Alocasia macrorhiza variegata, on the other hand, requires a different soil. Good turf loam two parts, rotten dung one part, with sufficient sand to secure quick and thorough drainage, suits this plant well. Palms may now be potted, using fibrous peat, with a moderate admixture of broken crocks and sand; being water-loving plants, unless well drained the roots become unhealthy. With longer days, the temperature of the stove ought to be increased 8° or 10° during the daytime, and 5° at night; closing early so as to shut in the sun's genial warmth, which is much better as well as more economical than fire-heat. Syringe the plants at the time of closing the house; and always let this be done sufficiently early to allow the foliage to dry before night. Stoves that face the south, or in gardening phraseology stand east and west, will require slightly shading during sunny weather; at least some of the occupants will need a little shade, and it is better to place such at one end of the house, and only shade that portion; as the less shade the better, if scorching can be avoided. Stoves that are built north and south do not require shading so early in the season.

Fern House.—Any potting that remains to be done here should be attended to at once. Many of the commoner kinds reproduce themselves freely. It is therefore always well to keep a quantity of these in small pots; they are useful for intermixing with large plants, the appearance of which is much improved by an admixture of small ones; and if the latter are allowed to get somewhat pot-bound, their fronds will last in a cut state much better than those from plants more freely grown, and the better plants are saved from mutilation. All ought to be carefully picked over, removing such fronds or portions of them as are naturally decaying, yet do not cut out much that has life in it, as this has a tendency to weaken the plants. As the days lengthen, raise the temperature a little. Brown Scale is the greatest enemy of the Fern house, and with the approach of warm weather this pest will begin to increase apace if not checked. Every means should therefore be used to keep it down; as it soon renders the plants unsightly. As soon as growth commences, shade slightly during sunny weather, and allow more moisture in the atmosphere as well as at the roots. Give air on all mild days, otherwise the fronds push weakly; a condition that should be avoided, as leaves of that kind never maintain a healthy appearance so long as is desirable. If thrips makes its appearance, fumigate frequently yet not too strongly.

Orchids.—Proceed with potting, carrying out the operation in accordance with former directions. See that the plants are kept as free from insects as possible. White scale and a minute yellow thrips are their greatest enemies. The scale will thrive alike on those from the eastern or western hemisphere, on thick fleshily-leaved plants like Vandas, Saccabiums, or Aerides, as well as on the thin leaves of Miltonias, Lycastes, and Dendrobiums; the thrips attack most frequently the thin-leaved plants, yet if allowed to get the upper hand they will do much mischief to the young leaves of Phalaenopsis, Saccabiums, or Aerides. They usually secrete themselves down in the heart of the plants, where no amount of fumigation that can be used with safety appears to affect them. Continual syringing will keep them in check. Some growers object to syringing overhead; but, if it is done sufficiently early in the morning to allow the plants to get dry before night, with a reduction of atmospheric moisture, no bad results will follow. For the eradication of scale nothing is more effectual than the sponge and a camel's hair brush carefully applied. Increase the temperature 6° or 8° by night, with 8° or 10° by day, according to the state of the weather. Shade with thin material during bright weather, yet never allow it to remain down when not required.

Hard-wooded Plants.—All hard-wooded plants which it is necessary to pot during the spring ought to receive that attention by the middle of the month. If cold, cutting winds accompany bright weather, do not give any side air near where newly potted plants are placed; but let the top lights be opened. Shade and sprinkle water

about the paths and upon the stages where the plants are placed. Let all plants as they are potted receive what tying they require to put them in proper shape, especially young growing stock. Any omission in this matter is frequently fatal to symmetrical appearance, as the plants get older the young wood getting too stiff to bend. If mildew happens to exist on the ripe wood of last year, it will most likely attack the young growth as soon as the plants begin to move. This applies to such things as Boronia pinata, Hedraoma tulipifera, and Leschenaultia biloba. If such should occur, dust with sulphur at once. Azaleas that have been much affected with thrips last summer would be much benefited by a good washing with tobacco-water now, as the eggs that were deposited in autumn will soon come to life under increased temperature.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Tree and other Peonies.—It does not seem to be generally known that these fare well, and form valuable additions to the conservatory early in the season. A temperature of from 45° to 55° hurries them into bloom, and they may be had in flower in February or March. Several of them are sweet-scented, and all are interesting, and more or less beautiful. The chief use of such plants forced consists in their anticipating the spring or summer by many months.—D. T. F.

Lilium giganteum.—Will you kindly tell me how I can increase my stock of this noble lily?—J. FRISBY.—[There should be a few good suckers around the base of your old plants, which may be taken off with a heel when potting, and firmly placed in small pots, using a compost of finely chopped turfy peat and loam, some leaf-mould, and a good admixture of sharp river sand. A very gentle bottom heat would accelerate their rooting; they should be kept close for a few days, and shaded from strong sunshine.]

Hydrangea japonica.—I have a few plants of this Hydrangea, which I am at a loss how to treat, so as to have them in bloom early. Can you kindly help me?—G. FOX.—[If your plants are young they should be re-potted now, and such as show signs of flowering, if required early, may have a little extra heat to accelerate their blooming season. Should the plants consist of several branches, those not possessing flower-buds may be removed, and used as cuttings, in which case they make nice blooming plants by next spring.]

Myosotis dissitiflora.—This is one of the best of flowers for conservatory or for room decoration in February. Take up tufts of it from the open border, say a month or six weeks before they are wanted, and keep them in a temperature of from 45° to 50°, and they will flower profusely. They remain a long while in flower, and never look so lovely and delicate as when under glass. Everybody likes them in vases and bouquets—in short, this Forget-me-Not is a great acquisition any and everywhere for early flowers. It is not at all particular as to situation, and flowers freely in a room or cottage window.—D. T. F.

White Lilies.—Where can I get the white variety of lilac so commonly seen early in the Paris markets?—A. WILLIAMS.—[The lilacs about which you inquire consist wholly of the ordinary purple kind, which is forced in pots. After being lifted they are placed in a cool house for a little while, after which they are subjected to a high temperature, with plenty of water overhead and at the root, and kept in total darkness by means of covering the pots in which they are grown with straw mats, &c. The lilac colour by this means is exchanged for one of pure white, and the bloom is of a better quality than if the true white variety had been used.]

Cool Orchids for Conservatories.—Would you kindly name a few cool orchids for the conservatory, those easiest to grow and obtain?—CLARA.—[Orchids in general require a little extra heat when making their growth, but we think the following may suit you: Barkeria Skinneri, Cattleya citrina, Cypridium insigne, Caelogyne cristata, C. odoratissima, Disc. grandiflora, Epidendrum vitellinum, Goodyera macrantha, Laelia anceps, Lycaea Skinneri, Masdevallia ignea, Miltonia spectabilis, Odontoglossum grande, Phaius grandifolius, P. Wallichii.]

Solomon's Seal.—I can endorse all that Mr. Hobday says about this. No plant is easier forced or more useful, either in pots or for cutting. It is improved alike in leaf and flowers by forcing. Few flowers are more striking in tall vases, and the tiny tubes mounted singly or in threes, give chaste variety in a bouquet that puzzle many and gratify everyone. The single leaflets mounted are likewise serviceable for fringing; altogether it is charming. Smaller plants, with from three to six flowers, form model table plants.—D. T. F.

Chinese Primroses.—We beg to send you from our seed grounds at Noss specimens of our Chinese Primroses. Amongst them, as you will see, are some novel things, such as the Madder red-shaded crimson, which we call Florence, and the double variety of the same; the double red, double white, double white fern-leaved, double spotted; then the white with the yellowish green centre, the lilac margined white, and others.—STUART & CO.—[A charming collection of blooms, generally of large size, finely varied in colour, of good substance, and altogether extremely beautiful. Among the best are Village Maid, double and single, bluish, mottled, and flaked with crimson; double red, purplish crimson full and handsome; carmine alba punctata, rich deep crimson, thickly dotted with white; double Florence, brilliant in colour and very double, while the single variety is equally fine in colour; lilacea alba punctata, deep lilac, covered with minute white spots; lilacea alba marginata, bright lilac, distinctly edged with white; red fern-leaved, also a fine kind; all, in short, lovely more or less, and well deserving of cultivation.]

THE COW PARSNIP (HERACLEUM).

TIMES and fashions change; colour has had its day, and form now begins gradually to assert its right to due recognition. You have already given in your columns some examples of plants remarkable for fine form, and nobility of aspect, and now I shall proceed to add a few more to their number.

The genus *Heracleum*, numerically speaking, is not a large one; and, owing to the great sameness of general contour that presents itself among its species, I shall not be far wrong when I say that the maximum of beauty as well as of gigantic development appears to be monopolized by one species, and that tolerably familiar to most people by the very appropriate name of the Giant Cow Parsnip—(*Heracleum giganteum*)—a synonym that has become so thoroughly popularized that in referring it to its true specific name, *H. sibiricum*, I have no wish to insist in laying claim on its behalf to the usual rights of priority as regards nomenclature. It is a widely distributed plant in the wilds of Siberia, and one which of all others gives the most marked character to the herbaceous vegetation of our northern hemisphere so admirably illustrated in one of the early numbers of THE GARDEN, and exquisitely individualized in the accompanying woodcut.

It was introduced into this country some thirty-five years ago, and is a grand plant for the wild garden, and were it not for the fact that its maximum of beauty is attained soon after mid-summer and succeeded by a very rapid decay, it would deserve a place in the sub-tropical garden. The early removal of the flower stems would not only add vigour to its artistically cut and arranged leaf development, but also protract its beauty for a much longer period than otherwise. I have grown this plant with flower stems as much as fourteen feet high, the crowning terminal umbel being more than two feet across; and in a wild corner during

the succeeding winter, long after all trace of foliage has disappeared, the ghost-like reminiscences of former life which these stems present have a beauty of the melancholy type peculiarly their own. It is a most abundant seeder, and after it has become once established, I would recommend the removal of the flower stems while the seeds are still adherent, or it may soon outrun the bounds allotted to it. For a small wild island in a lake no plant can be more appropriate. There, of course, its vagrant propensities will be curbed by the limit of its island home, and its roots dipping far below the water level will drink in a bountiful supply of that great essential towards vigorous development. I may also state that this plant has qualifications that warrant its claiming a place no less aristocratic than in our metropolitan squares or town gardens generally. In one of the narrowest and oldest streets in Hull, under the very shadow of the house that gave the great Wilberforce birth, it yearly attains a height of ten or twelve feet, and looks wonderfully luxuriant. I should, however, add that possibly some of this luxuriance, displayed under otherwise adverse circumstances, must be attributed to

a bountiful supply of guano and other artificial manures from the adjacent warehouses.

HERACLEUM WILHELMSHI claims a near relationship to the foregoing, but is smaller in stature, rarely exceeding six feet, its leaves are less rigidly cut and shorter in the foot-stalk; the individual flowers are also larger and more closely arranged in the umbel, its most noticeable general feature being its denser and more compact habit.

H. FLAVESCENS, with its variety *angustifolium*, which is sometimes elevated into specific distinction, both possess characters sufficiently distinct from each other. The latter has long narrowly-divided leaves, and is decidedly the more elegant of the two. In both the species and variety the foot-stalks and veins of the leaves are covered with soft straw-coloured hairs, whence originates the specific name.

H. EMINENS is a species of more recent introduction, and one which I have not yet seen under circumstances sufficiently favourable to justify me in expressing an opinion respecting it.

The dense covering of downy hairs which it has on the leaves, combined with their massive and rounded outline, must, however, I think, have a very charming effect.

H. ABSINTHIFOLIUM.—Some little time since this was noticed in one of the gardening periodicals, and accompanied by a figure which does not appear to me to convey anything like a correct idea of the true plant. I have grown the *Zozimia absinthifolia*, to which the former is a synonym, and its foliage is so finely divided as to come under the descriptive character we find in books of "foliis decompositis"; it is with me neither a very vigorous grower, nor does it possess any very marked character worthy of recommendation.

I need only add to the foregoing remarks, that all the species are fond of good, rich, moderately damp soil, and therefore where the latter is poor and sandy it must be sup-

plemented with a bountiful supply of manure.

J. C. NIVEN, Botanic Gardens, Hull.

ARTIFICIAL FLOWERS AND THEIR MAKERS.

There are about 170 firms of artificial florists in London. Of this number perhaps not more than one-half are manufacturers; the other half, although describing themselves as florists, are either wholesale dealers or importers of foreign goods. Of the manufacturing firms, about ten houses each employ 200 hands, and ten more each find work for 100 hands; the smaller houses keep from twenty to thirty, and some even as few as six or eight. There are outdoor workers as well as indoor, and including both, it may be fairly computed that at the present time from 4,000 to 5,000 women and children find employment in this fancy trade, which is divided into branches: rose-makers, pattern-makers, preparers, cutters-out, jet, silk, satin, and leaf hands, and mounters, being the titles by which the branches are distinguished. First-class hands can earn 20s. to 25s. per week if fully employed, but the average earnings may be said to not exceed 15s. There are, however, highly talented artists, who make from £100 to £150 per annum; these, as a matter of course, are educated women, possessing a knowledge of botany, and skilled in ornamental art.

Cow Parsnip.

Second-class hands earn from 15s. to 20s. per week, but as work fluctuates with this class more than with the first, the average may be taken at 10s. Some years back the trade was found to be a very unhealthy one, as, indeed, were most trades in which colours are used. We have ourselves seen strong men bleed profusely at the nose whilst engaged in dusting emerald green or ultramarine powder on a number of pieces of artistic work. Emerald green (at least the mineral colour known as such) has been abandoned by the flower makers, and something less harmful, we might say harmless, substituted. The only colours now used are aniline dyes, and the trade is much more healthy on that account.

Many buds, grasses, and mosses are of foreign manufacture, and are imported from Paris and Berlin, to be made up and mounted by British hands. Flowers, stamens, petals, pistils, and leaves are mostly of English make. French buds and leaves, combined with English flowers, and mounted by British florists, command the highest prices, and are mostly patronised.

Having ascertained these few facts from the proprietor of a large manufactory in the city, Mr. W. Jones, 16, Redcross Street; that gentleman kindly invited us to an inspection of his workrooms; he himself accompanied us and explained the various processes, often delighting us and calling forth our admiration by exhibiting samples of finished bouquets, as we proceeded on our tour among the roses. First our attention was directed to the huge piles of white muslin as the chief material used in the manufacture. We were next shown some muslin which had been dyed a most verdant green and then calendered; this was ready for forming into leaves, cutting up into blades of grass, or for a hundred other purposes.

We now proceeded to the leaf-makers' room. Here were cutting presses and steel cutters, and some of the large sheets of green muslin were being stamped into various-shaped leaves; there were also embossing presses, fitted with steel dies, on which had been cut the veins of the leaves. After being shaped and duly embossed, the leaves are handed over to some young females who sit beside cauldrons of boiling bees' wax, into which each leaf is separately dipped, and then laid out to dry; this gives the glaze to the leaf, and makes it appear almost natural. One of the young females said she could dip 100 gross of leaves in a day. We ascended to the rose-makers' room. We thought we were

"Down in a flowery vale,
All on a summer's morning."

We have many a time and oft visited Covent Garden Market in the early dawn, and revelled in the glorious sight there presented to our view, and in the rich perfume the flowers exhaled. We were strongly reminded of those spring and summer treats by what we saw here, but the rich odour, of course, was wanting. In the centre of a light, lofty room stood a long work-table, on which lay scattered every conceivable particle from which a flower could be made. There were roses, lilies, fuchsias, geraniums, violets, snowdrops, convolvuli, daisies (I might almost continue to the end of the floral calendar), all in bits—as if Master Robin Goodfellow, otherwise known as Puck the Mischievous, had stolen into Queen Titania's conservatory, and wantonly picked every flower, bud, and leaf to pieces.—*Woman.*

PUBLIC GARDENS.

VICTORIA PARK: ITS PRESERVATION AND EXTENSION.

WHEN the ground was purchased by Government, in 1842, for the purpose of forming a park for the use of the dense and rapidly-increasing population of Eastern London, a certain portion was reserved as building land, the ground-rent arising from which might, it was thought, produce an income sufficient for the maintenance of the park, and possibly serve to reimburse, to some extent, the original outlay.

The inhabitants of the surrounding districts are now seeking to prevent further building on the reserved ground, and to have the portion still remaining unlet to the builders thrown into the park. Mr. Lowe, however, turned a deaf ear to the deputations that waited upon him with that view, being determined, as keeper of the national exchequer, to stand upon his rights rigidly, on the prevailing principle of strict political economy. The people of the Tower Hamlets, and especially the inhabitants of Hackney, were indignant at the resistance offered to their prayer, declaring that the vastly increased population of the neighbourhood required a proportionate increase of breathing space in the shape of such open places as might be readily available, like the still open belt of adjoining

land, which was purchased with the national money along with that forming the park.

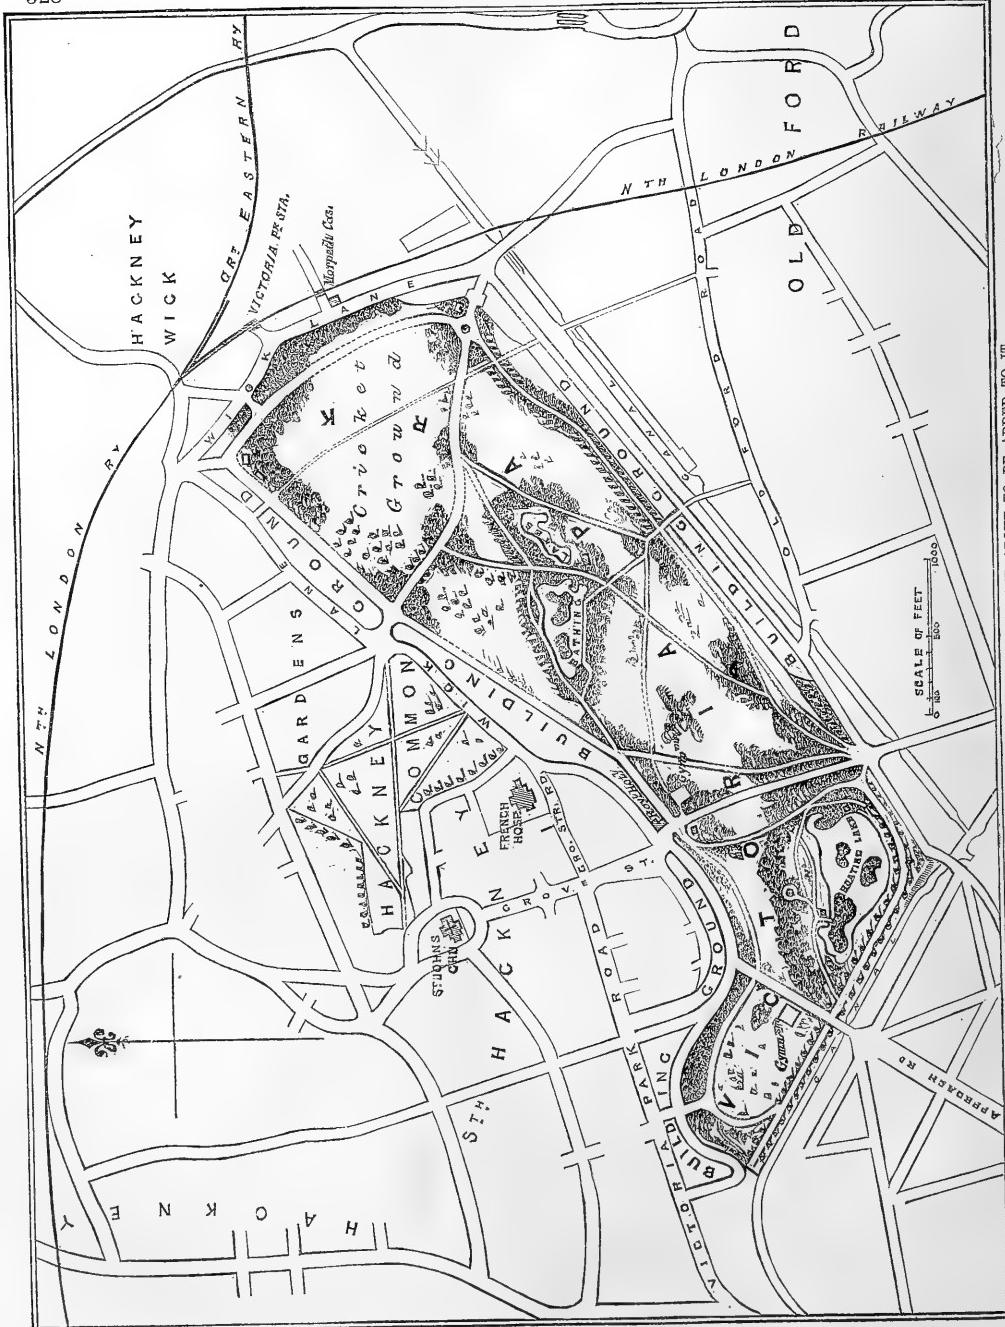

The press has, to a certain extent, sided with the Chancellor of the Exchequer in considering that the people of Hackney and adjoining districts were unreasonable in demanding a further outlay for their particular benefit out of the taxes of the country at large; while, on the other hand, the advocates for preserving all the open land possible for the benefit of the overcrowded inhabitants of the densely-built district of Bethnal Green insisted that Mr. Lowe was acting with a Shylock-like determination to have his bond, and nothing but his bond, even at the cost of any amount of human life. A good deal of sharpish invective has been used on either side; and by many of those not immediately interested, both among the writers of the public press and the ever-busy letter-writers that are always to be found among the general public, very opposite opinions have been arrived at without a complete knowledge of the facts of the case.

The editor of *THE GARDEN*, in that portion of the publication devoted to public parks and gardens, has thought it advisable to obtain, on the spot, the fullest information connected with the points in dispute, and to make known the results, accompanied by a carefully engraved plan of the park, the disputed ground, and other open ground lying near at hand, without which assistance it is utterly impossible for the public to arrive at a just conclusion regarding the pretensions on either side.

It will be seen, on reference to the plan, that the original laying out of the park was exceedingly well conceived. In the first place, the park was divided into two main sections, the one for the recreations of walking or riding—to which purposes the West End parks are entirely devoted, to the exclusion of cricket, foot-ball, or any other athletic games or exercises. The second section of Victoria Park was laid out with the express view of rendering it available for cricket, foot-ball, and other open-air games tending to the healthy exercise and amusement of the population of East London. Bathing was also suitably provided for, a lake of considerable dimensions being surrounded by shrubberies, with a private path of approach for bathers only, as will be seen by reference to the annexed plan—an arrangement far in advance of that utter neglect of the decencies which still prevails in Hyde Park in the bathing season. Everyone, on either side of the question in dispute, will be glad to learn that the whole of the plantations in the park have thriven well, and are in a state of vigorous growth, especially an avenue of young elms, which are destined to become a grand feature in Victoria Park some few generations hence. A fine architectural feature in the park is the drinking fountain, one of the first of its class, which was erected at the expense of a well-known munificent lady, then Miss Burdett Coutts.

There was much enthusiasm displayed concerning the original purchase, planning, and embellishment of Victoria Park; even Joseph Hume, generally disposed to hold the national purse-strings as tightly as possible, giving his cordial support in every way; while private individuals aided in the work after various fashions—Mr. Dixon presenting two of the stone alcoves which formerly stood on old London Bridge, which form solid looking park features of a substantial character, both useful and ornamental. They bear suitable inscriptions briefly stating their history, on which account they will long remain objects of considerable national interest.

It will be seen by the annexed plan that Hackney Common, containing something less than a score of acres of open ground closely adjoins the park, and at one point is only separated from it by a roadway. Here there is a means of extension without interfering with Mr. Lowe or his bond, which has not been mentioned in the newspaper discussions. It appears, however, that Parliamentary interference may be necessary to remove a few technical impediments to the incorporation of the common with the park; an addition which some consider, as we were informed by residents in the neighbourhood, would be a sufficient increase of space. This point has not been brought forward in any of the letters and leading articles which the contention for breathing room at the East End of London has led to. It is time, however, to come to the precise point in dispute—namely, the belt of ground

VICTORIA PARK, SHOWING THE DISPUTED GROUND ABOUT TO BE ADDED TO IT.

encircling the park, which was set apart as building ground. A portion still remains unappropriated to that purpose, as is distinctly shown on the appended plan. That portion, amounting to $29\frac{1}{2}$ acres, is the space which it is requested may be permanently annexed to the park land. It is, virtually, a part of the park, being within the ring fence by which it is enclosed; and being still in turf, and only separated from the rest of the land by a slight iron rail, any casual visitor would take it for a permanent part of the actual park, and could not fail to feel both surprise and regret if suddenly informed that it was about to be built on, and the area of the park narrowed by the absorption of that pleasant and tolerably broad green strip into the surrounding chaos of bricks and mortar.

It only remains to state what the advocates urge as their reasons for setting up their claim that the belt of still open green land ought to be permanently added to the park. The position taken up by Mr. Lowe and his supporters is, that the park was purchased and presented to Hackney and the surrounding districts on certain conditions; adding that it would be manifestly unfair that the whole nation should be taxed in order to enlarge a park for the special benefit of East London. As to Mr. Lowe's first proposition, their answer is this: When Victoria Park was first established, it was distinctly stated by two of the Commissioners, at different times, Lords Morpeth and Duncannon, that if the surrounding population very much increased, the space set apart for leasing to builders should be incorporated with the park. This understanding was very soon to a certain extent ratified. It being subsequently conceded that only one-sixteenth, instead of one-eighth should be set aside for building. The principle being thus established of extending the original limits of the park, at all events to the extent of any building ground left uncovered, if greatly increased population should render it desirable. The actual increase of population since the formation of the park is thus stated by Dr. Tripe, the medical officer of the Hackney District:—According to the census of 1841, the population of the surrounding districts was 530,280; while in 1871 it had risen to 839,647; a vast increase, in proportion to which the addition of the $29\frac{1}{2}$ additional acres to the park would be very inadequate. These facts sufficiently dispose of Mr. Lowe's first position.

The logic of his second position is not more tenable. He says it is unreasonable that East London should obtain breathing room at the national expense. If that principle were acknowledged to be unanswerable, then Mr. Lowe is bound to sell the whole of Victoria Park (which he could do at a good profit), and put back the sum realized into the national exchequer; for it was bought with the national money, furnished by the whole of the taxpayers of the United Kingdom. Again, if the shallow argument put forward be sound, how is it that the Chancellor of the Exchequer goes on sanctioning the great annual outlay on the West End parks, which during the last ten years has been at the rate of £59,000 a year, as shown by Mr. Holmes, M.P.? In what does the principle differ, as between East End and West End parks? But Mr. Lowe's argument is neither logical, statesman-like, nor charitable. What were the words of Mr. Hume—Joseph Hume, the friend of the people? Why in speaking of public parks and places of recreation (in reference to the formation of Victoria Park), he said, "I want the business done for the people in every part of the realm; and, whilst I have succeeded for the working classes in Edinburgh, Liverpool, and other places, I look with confidence to the success of those who have taken up the subject in the best possible manner in the Tower Hamlets."

Thus we see that the principle of affording breathing spaces for overcrowded populations wherever they may occur, out of the public purse, has been not only acknowledged, but already acted on. The petty view, that each spot should pay for its preservation from the evils of overcrowding or any other unavoidable evil, is justly and irrevocably exploded. The equalization of poor rates being one of the newer and better principles which apply to this case; in the wholesome action of which, Belgravia and St. James's, with comparatively no poor, will be made to contribute their just quota towards the maintenance of the poor of St. Giles's and other districts where the poor abound. The noble letter of Mr. Fawcett, and

the combined efforts of the members for the district, the Rev. D. Hansard, and other members of the Victoria Park Preservation Committee, aided by the energy and efficient activity of Mr. Heath, their hon. secretary, will doubtless, as there is now every reason to believe, be crowned with the success they deserve.

They have placed the matter in the fitting hands of the Metropolitan Board of Works, and now ask for even more land than the $29\frac{1}{2}$ acres in dispute; suggesting that the 125 acres originally secured as a site of the once proposed concentration of the gas works of the metropolis should be added to the park, its close proximity rendering the junction comparatively easy. This addition, or an equivalent enclosure from the still available open land at Hackney Wick, with the addition of Hackney Common, would scarcely bring the East End park up to the dimensions of Regent's Park; while the surrounding populations are so much more numerous, and so much more densely crowded.

H. N. H.

KEW GARDENS.

INTERESTED by the remarks on these gardens (p. 217) I was induced to pay them a visit, at a season certainly when they were not seen to the best advantage; yet, when free from the dazzle of masses of flowers, one is able all the better to appreciate what has been done, and what is doing, in the distribution and arrangement of the grander features of the place, namely, its noble trees, fine slopes of turf, and other great natural advantages.

On entering the gardens from Kew Green, one used to be pleasantly impressed by the aspect of grand unbroken spaces of turf, varying in light and shade according to their wavy undulations, and out of the smooth green surface of which arose the trunks of finely-grown forest trees, producing an open and park-like effect, full of a kind of repose and grandeur which was very grateful after miles of closely-built suburbs that have to be traversed before Kew can be reached from London. But instead of the well-remembered impression of free space just alluded to, I found, on this occasion, the general appearance of the place at the entrance sadly changed for the worst. The smooth expanse of turf was dotted all over with small, and sometimes very shabby, shrubs, each making a disagreeable spot, that one longed to remove at once, as it impeded and broke up the view of the stately trunks of the big trees, while it presented in itself no characteristic either as to rarity or beauty that could for a moment recommend its preservation; at all events, not on the spot where it had been so obtrusively and tastelessly placed.

The disturbing influence of the petty, dotty plantations has entirely obliterated all appearance of breadth, and imparted a confined and uncomfortable aspect to the place, as though there were not room enough, and shrubs had to be stuck about everywhere, without regard to taste, simply because, from some incomprehensible necessity, they had to be planted, and there was no room for them anywhere else. This new grievance awoke attention to the formal kidney-shaped beds of Rhododendrons which occur, one after another, on each side of the main walk, till their repetition becomes absolutely nauseating; while equally formal masses and hedges of common laurel (a plant which does not thrive particularly well in the soil of Kew), afford the only marked variation that is to be found in the way of evergreen shrubs. Surely, in the noble garden of Kew something more ought to be done to gratify the public eye—say, by planting a few scores, at all events, of some of the thousands of forms of exquisite foliage with which our subject woods and mountains in all parts of the world have enriched us.

Such ill-conceived and badly carried out devices are the more regrettable, as there are closely neighbouring features, both natural and artificial, which must strike all spectators as remarkably fine. The Great Palm House, for instance, notwithstanding certain blemishes in the design of the entrances, displays a grander series of graceful lines and curves than any structure of the class in Europe. Then there are the two noble twin limes, finely grown trees of unusual beauty, which are rendered still more interesting by the great bushes of mistletoe rooted on their branches; the mistletoe being so

rarely seen on the lime. There are also to be seen several very remarkably fine specimens of silver-barked birch, so picturesque in growth and form, and of such unusual size as to suggest that we are enjoying a glimpse into some grand glade of natural forest. Surely, with materials such as these to work with, far better results might have been achieved than those we see in progress in these naturally beautiful grounds. What a noble vista is the Sion Vista, terminated by the glorious waters of the Thames at one of its grandest bends! and there are several other natural features equally fine in this truly royal garden. Yet, that unrivalled vista, thus nobly terminated, is actually threatened with being utterly blocked up by injudicious planting. The great rows of Deodars which were planted to flank it several years ago, and which are now making fine growth, were destined to become a grand feature; but why plant Douglas firs in front of them?

In the Pagoda Vista, which has already been blocked up at one end, similarly injudicious planting is actively proceeding; especially an interior avenue composed of a series of groups of three trees, only four feet apart from each other. These trees, being oaks, beech, ash, and other trees of large growth, will most probably choke each other in a few years; and will, if they should escape self-suffocation, impede altogether the view of the Deodars. The wholesale destruction of natural beauty that is going on close to the Pagoda struck me as still more extraordinary. There is, or rather was, a fine green knoll there (opposite the new winter garden), crowned with an irregular and highly picturesque group of old cedars and other trees. Their great trunks, with the rugged pinky-tinted bark, which assumes a warm, glowing rose-colour in a bright sunlight, rise boldly like noble vegetable columns from the smooth, green sward, crowned with their spreading canopies of dark-green, like the stone pines of the south, which form such charming objects in Turner's Italian scenes. Well, it has been, as it seems, deemed advisable to hide this nobly picturesque group of Pinasters; and several plantations of young firs and other shrubs, enclosed within common laurel hedges, have been already made apparently for that express purpose. The only traceable object which could otherwise have led to this seeming piece of wilful vandalism is, possibly, the intended formation of a series of narrow avenues radiating from the winter garden, one of which, formed by rows of Arbor vita, is only nine feet wide. Now, can it be possible that it is intended thus to shroud the Pagoda with a kind of "Asian mystery"? or have the devisers some other object to realise? If so, whatever it may be, it is certain that the loss of the fine natural scene they are destroying in order to effect their purpose, will not be compensated for by any results at present apparent.

Next, let the spectator take his stand in front of the conservatory, and look across towards the Richmond Road. He will see, immediately in front, a piece of rising ground, on which stand some remarkably fine trees of various kinds, among them a noble Cedar. This group, with the towering spire of Douglas fir rising from among the mass of foliage, is one of the most picturesque features of the garden. Nevertheless, its view is about to be confused and obstructed, as far as possible, by the interposition of petty plantations of mean shrubs and solid square patches of cropped laurel. Such proceedings appear simply incomprehensible.

NOEL HUMPHREYS.

The Mountain Flowers.—Together with this great source of pre-eminence in mass of colour, we have to estimate the influence of the finished inlaying and enamel work of the colour-jewellery on every stone; and that of the continual variety in species of flower; most of the mountain flowers being, besides, separately lovelier than the lowland ones. The wood hyacinth and wild rose are, indeed, the only supreme flowers that the lowlands can generally show; and the wild rose is also a mountaineer, and more fragrant in the hills, while the wood hyacinth, or grape hyacinth, at its best, cannot match even the dark bell-gentian, leaving the light-blue star-gentian in its uncontested queenliness, and the Alpine rose and Highland heather wholly without similitude. The violet, lily of the valley, crocus, and wood anemone are, I suppose, claimable partly by the plains as well as the hills; but the large orange lily and narcissus I have never seen but on hill pastures, and the exquisite oxalis is pre-eminently a mountaineer.—*Modern Painters.*

THE ARBORETUM.

THE MONTEREY CYPRESS.

(*CUPRESSUS MACROCARPA*.)

GENERAL resemblance, or, what naturalists call, "facies," is a character that rarely fails to lead to a true estimate of the affinities of species. Even the apparent exceptions may, in the end, turn out to be no exceptions, but indications of a connection which we repudiate on the strength of other characters, which, in reality, may be less persistent or less significant, although more structural. Our sketch affords, on the other side, a good example of such a revelation of affinity. Most people, at first sight, would say, "that is the representation of two or three old Scotch firs, or perhaps of some old stone or umbrella pines (*Pinus pinea*) in Italy." But they are not firs at all; they are Cypresses—fine old specimens of the *Cupressus macrocarpa* growing on the coast near Monterey, in California. In Mr. Hartweg's first account of it, indeed, he described it as forming "a tree sixty feet high, with a stem nine feet in circumference, with far-spreading branches, flat at top like a full-grown Cedar of Lebanon, which it closely resembles at a distance." The reader is now enabled to judge as to this for himself. We have stated the impression which it produced on us.

This species may be regarded as the representative or equivalent of our largest European Cypress (*the Cupressus sempervirens*) on the Pacific Coast of North America. Like it, it reaches a great age and a great size; its foliage is similar, and as in it, the fruit is large and hard, differently shaped, indeed, being oblong instead of round, but of the same character, and nearer it than any other well-defined type of Cypress.

It has been known since 1838, when Mr. Lambert gave the Horticultural Society a few seeds of it, without name or indication of locality. It then received the manuscript name of *Cupressus Lambertiana*, and, as it was easily propagated by cuttings, it soon got pretty widely distributed in gardens in England under that name. It was afterwards received, through Dr. Fischer, of St. Petersburg, as a new species of Cypress from California, but still unnamed and undescribed. It was next introduced in greater numbers by Mr. Hartweg, who had been sent out to Mexico and California by the Horticultural Society to collect plants for them. In sending it, he gave it the name of *C. macrocarpa*, from its large seeds, and it was described and published under that name in 1849 by Mr. Gordon in the *Journal of the Horticultural Society*. So it stood for a number of years, those who may be styled the old holders calling it *C. Lambertiana*, and the new holders calling it *C. macrocarpa*. But, like many other plants—we had almost said, more than most other plants—the Cypresses indulge in individual variations, every seed-bed producing peculiar modifications; and as with other species so with this, it was soon observed that varieties showed themselves, among which, the most remarkable, from their opposition of habit, were two, one growing straight and narrow, more or less pyramidal, or approaching the fashion of the Lombardy Poplar—the other more spreading, and like the beech or the cedar. Horticulturists, finding that they had two names and two marked varieties of this Cypress, forgetting the origin of the names, naturally set themselves to apply them to the two varieties. At first, of course, confusion became worse confounded, but gradually the gardening world have got to distinguish the two varieties, and habitually to apply the name *C. macrocarpa* to the upright growing plants, and *C. Lambertiana* to the more spreading plants. Mr. Gordon has ascribed this difference to the first plants having been chiefly cuttings; but it is beyond doubt that the upright and horizontal varieties are both found as seedlings in beds raised from seeds of the same tree. As these two forms are generally so well marked as to make it an easy task to assign any plants either to one or the other, it would seem that there can be no harm—nay, that it is rather desirable—that they should continue to be known by separate titles; and as it is never desirable to disturb accepted titles when it can be avoided, we should suggest that the horizontal-growing form should continue to be known by the title of *C. macrocarpa*, var. *Lambertiana*, and the upright-growing one by that of *C. macrocarpa*, var. *fastigiata*.

THE MONTEREY CYPRESS (*CUPRESSUS MACROCARPA*) AT HOME.

The tree is fast-growing and beautiful at every stage of its growth, and in every form. Its verdure is exceedingly rich, dark, and luxuriant; its branches reddish; and the long, whip-like shoots impart a peculiar grace to it. Unfortunately it cannot be absolutely depended on as hardy in every position or district in this country. Mr. Palmer's tables show that out of 109 places reported on indiscriminately and without selection, during the winter of 1860-61, the tree was killed at half of them. In England it was killed at 43 out of 75. In Scotland at 14 out of 30. In Ireland only 4 places are reported on, and at those it escaped without any deaths or much injury. In England and Scotland it was in the midland counties that the chief mortality took place. In 1866—another severe winter—it suffered still more; all the fine specimens in the Botanic Gardens at Kew were then cut off, and generally the finest examples in Britain were swept away. In some more favoured places it escaped, and it may reasonably be expected that it will escape in such places again. Up to a certain age (which it will be long ere we reach in this country), the older the plants the stronger they will be, and the better able to withstand the severity of our climate. The finest examples which we have seen since 1866, are those at Castle Kennedy, in Wigtownshire, which are arranged in a semicircle, so as to show their luxuriance and beauty to the best advantage, and at the same time allow the two different types of form, of which we have above spoken, to be well seen.

Notwithstanding its liability to be cut off when a bad year comes, the beauty and grace of this tree, even in its young stage, are so great that we may be sure it will always hold a place around our English country houses. When killed it must be replaced. It should perhaps be noted that a variety of *Cupressus Lawsoniana* (a much harder plant) has been met with, possessing exactly the same habit and port as the *fastigiata* variety of *C. macrocarpa*; its colour, however, is not equal to that of the latter, although very beautiful in its own way; but the green of *C. macrocarpa* is peculiarly rich, and we remember no other Cypress which possesses it. A.M.

[For the sketch from which our plate of the Monterey Cypress was engraved we have to thank Mr. E. Vischer, of San Francisco, a gentleman who has long studied, and most faithfully sketched, many of the most remarkable trees, and much of the most picturesque scenery, of California.]

PINE FOREST IN THE JURA.

AMONG the hours of life to which the writer looks back with peculiar gratitude, as having been marked by more than ordinary fullness of joy or clearness of teaching, is one passed, now some years ago, near time of sunset, among the broken masses of pine forest which skirt the course of the Ain, above the village of Champagnole, in the Jura. It is a spot which has all the solemnity, with none of the savageness, of the Alps: where there is a sense of a great power beginning to be manifested in the earth, and of a deep and majestic concord in the rise of the long low lines of piny hills; the first utterance of those mighty mountain symphonies, soon to be more loudly lifted and wildly broken along the battlements of the Alps. But their strength is as yet restrained; and the far-reaching ridges of pastoral mountain succeed each other, like the long and sighing swell which moves over quiet waters from some far-off stormy sea. And there is a deep tendency pervading that vast monotony. The destructive forces and the stern expression of the central ranges are alike withdrawn. No frost-ploughed, dust-encumbered paths of ancient glacie fret the soft Jura pastures; no splintered heaps of ruin break the fair ranks of her forests; no pale, defiled, or furious rivers wend their rude and changeful ways among her rocks. Patiently, eddy by eddy, the clear green streams wind along their well-known beds; and under the dark quietness of the undisturbed pines, there spring up, year by year, such company of joyful flowers as I know not the like of among all the blessings of the earth. It was spring time, too: and all were coming forth in clusters crowded for very love; there was room enough for all, but they crushed their leaves into all manner of strange shapes only to be nearer each other. There was the wood anemone, star after star, closing every now and then into nebulae; and there was the oxalis, troop by troop, like virginal processions of the Mois de Marie, the dark vertical clefts in the limestone choked up with them as with heavy snow, and touched with ivy on the edges—ivy as light and lovely as the vine; and, ever and anon, a blue gush of violets, and cowslip bells in sunny places; and in the more open ground, the vetch, and comfrey, and Mezereon, and

the small sapphire buds of the *Polygala alpina*, and the wild strawberry, just a blossom or two, all showered amidst the golden softness of deep, warm, amber-coloured moss. I came out presently on the edge of the ravine: the solemn murmur of its waters rose suddenly from beneath, mixed with the singing of the thrushes among the pine boughs; and, on the opposite side of the valley, walled all along as it was by grey cliffs of limestone, there was a hawk sailing slowly off their brow, touching them nearly with his wings, and with the shadows of the pines flickering upon his plumage from above; but with a fall of a hundred fathoms under his breast, and the curling pools of the green river gliding and glittering dizzily beneath him, their foam globes moving with him as he flew. It would be difficult to conceive a scene less dependent upon any other interest than that of its own secluded and serious beauty; but the writer well remembers the sudden blankness and chill which were cast upon it when he endeavoured, in order more strictly to arrive at the sources of its impressiveness, to imagine it, for a moment, a scene in some aboriginal forest of the New Continent. The flowers in an instant, lost their light, the river its music; the hills became oppressively desolate; a heaviness in the boughs of the darkened forest showed how much of their former power had been dependent upon a life which was not theirs, how much of the glory of the imperishable, or continually renewed, creation is reflected from things more precious in their memories than it, in its renewing. Those ever springing flowers and ever flowing streams had been dyed by the deep colours of human endurance, valour, and virtue; and the crests of the sable hills that rose against the evening sky received a deeper worship, because their far shadows fell eastward over the iron wall of Joux and the four square keepers of Gramson.—*The Seven Lamps of Architecture.*

HARDY TREES AND SHRUBS.

WE this week commence a series of notes on this subject, by Mr. George Gordon, A.L.S., long superintendent of the arboretum in the Royal Horticultural Society's gardens at Chiswick. The notes will be chiefly devoted to valuable, but neglected, rare, or half-forgotten subjects. Few have paid more attention to trees and shrubs than Mr. Gordon, and none are better fitted to advise us in the matter; as, in addition to a rich knowledge of hardy trees and shrubs, he has also the rarer knowledge of the conditions that suit them best, and a taste for arranging them that their beauties may be seen to greatest advantage in our gardens.]

THE SIBERIAN SALT TREE (*HALLIMODENDRON ARGENTEUM*).

The Salt Tree thrives well in any good garden soil, and if a little salt be given old plants of it occasionally, it greatly improves their growth. This plant is propagated by means of seeds, by cuttings of the roots, and by grafting it on the laburnum or the arborescent Caragana. When the latter, however, is used for the stock, it is apt to throw up suckers close to the ground, and, therefore, it is not so good for the purpose as the laburnum, which does not do so. The name is derived from "Hallinos," maritime; and "dendron," a tree, in reference to the plant growing naturally in salt fields and saline steppes near the river Irtysh, or Irtis, in Siberia. It was first introduced in 1779.

It forms an irregular, much-branched, deciduous shrub, from four to eight feet high, when planted in the open border on its own roots; but when grafted standard high on the common laburnum, it forms one of the most graceful drooping plants that can adorn a lawn or shrubbery. The leaves are alternate, abruptly pinnate, with two pairs of small leaflets, clothed with a whitish silky down, deciduous, and with the petioles and stipules spinose. The flowers are of a fine rosy purple, sweet smelling, pea shaped, tolerably large, and produced in great abundance on two and three-flowered peduncles, from the end of May to the middle of July, or even later, if the season be moist. The young plants, however, flower but sparingly at first; but when they attain size and age, they bloom profusely. The pods are inflated, or bladdery, hard, ovate, brown, and contain but few seeds.

Its synonyms are *Robinia Halodondron*, *Caragana argentea*, and *Halodendron argenteum*.

THE AMERICAN BURNING BUSH (*EUONYMUS AMERICANUS*).

The American Burning Bush is a sub-evergreen, loose, spreading, recumbent shrub, from three to six feet high, which requires to be planted in a partially-shaded and moist situation. It is a native of North America, and is found from Canada to Florida, among rocks and in moist woodlands. It was first introduced in 1686 by Mr. James Sutherland, at that time curator of the Edinburgh Botanic Garden. The *Euonymus americanus* forms a fine ornament in the autumn, when loaded with deep crimson fruit, intermixed with dark, glossy leaves; and, when viewed from a distance, when the sun is

shining upon it, it appears as if on fire, hence its American name of the "Burning Bush." It is also called the "Strawberry Tree," on account of its warty capsules.

The leaves of the American Burning Bush are elliptic-lanceolate, and serrated on the edges, from one to two inches long, leathery in texture, almost sessile, dark, shining green above, with the upper ones often slightly falcate, and all of them mostly acute pointed, and either tapering to or obtuse at the base, more or less persistent or evergreen, and especially so in mild seasons. Branches, slender, spreading, and recumbent, with the shoots smooth, quadrangular, and deep green when leafless. Flowers, small, yellow tinged with red, and produced in great abundance, in from one to three flowered panicles, in May and June. Fruit, a prickly, warty capsule, of a deep crimson colour when ripe, somewhat resembling the fruit of the common arbutus or strawberry tree, but not nearly so large. Seeds, white, with an outer scarlet covering, and ripe in October.

Synonyms: *Enonymus alternifolius* and *E. sempervirens*.

G. G.

THE ARBORETUM FOR MARCH.

BY JAMES BARNES.

FINISH up all trenching, draining, planting, and pruning; clear out water-courses; tie up and remove, or stack, all felled stuff, faggots, and cord wood; cutting out and placing by itself anything fit for charcoal. Bed out all seedling, layered plants, and last year's struck cuttings. Make preparations for, and sow the seed of various forest trees, such as Oak, Beech, Ash, Sycamore, White and Black Thorn, Yews, Evergreen Oak, Hollies, Furze, Broom, &c. See that all newly-planted trees are upright and firm in the ground, and that such as require it are staked and tied. Prepare healthy open, sandy, sweet borders and quarters, in which to sow the seeds of the various kinds of conifers. The Scotch Fir and its varieties, all of which are very hardy, should be sown on well-prepared soil, in beds of four or five feet wide, in open quarters. The tender and more spare seedling kinds, of which one only has small portions of seed, I have always sown on nicely prepared borders in sheltered situations. Very small portions of seed of such as are considered difficult to raise I have sown in boxes or in pans, and have placed them under a cold frame or pit lights; and great rarities I sow always in pots, plunged in sand or cinders ashes, close to the glass of a northern aspect, or placed so as to face north in summer; pricking the young plants off as soon as up into pans an inch asunder each way, or one plant into a small sixty-sized pot. Such has been my practice, which for many years has been very successful. Common and abundant kinds, sow in beds and quarters patted or beaten down gently with the back of a clean spade to firm the soil, covering it according to its size from half an inch to one inch in depth with open, healthy, sandy soil. Those in pots, pans, and boxes, I cover with charcoal dust intermixed with the soil, using it also on the border and beds.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Acer Negundo variegatum.—This beautiful maple has not yet received the attention which it merits, for few variegated trees equal it for effect when planted in masses or singly. I have a few trees of it produced when it first came out; they are now about fourteen feet in height, and the variegation is still as beautiful as when they were young. When planted in shrubberies, or for park scenery, this maple would have the same effect on a large scale as the finest silver variegated pelargoniums have on a small scale in our flower gardens. Cut sprigs of it are likewise useful for mixing with flowers for table decoration, or for other purposes. WILLIAM TILLER, *Hebeck*.

Moving a Tree with Nest.—I shifted a yew tree out of a plantation, distant at least 300 yards from my house, and planted it within a dozen yards of my front door. There was a blackbird's nest in the tree, which was finished, but had no eggs in it. To my very great surprise I saw a blackbird on the nest the very next day, and before I left home she was sitting on five eggs. That the old bird should follow a nest of newly hatched young I can imagine; but I never before heard of an instance like the one I name.—*Deafult, in "Field."*

An Old Yew Tree in Bavaria.—In one of your articles on Sequoias you refer to old Yew trees. I have found on a hunting tour in our mountains a yew tree of the following dimensions: circumference, 4·157 metres = 13 feet 6 inches; height, 7·3 metres = 23 feet 9 inches; diameter of the old tree, 1·328 metres = 50·7-10ths inches; diameter of a young tree, 0·0846 metres = 3½ inches; annual layers, 98; 98 × 1·328

age of the large tree, 0·0846 = 1,538, years. As, however, the annual

0·0846

growth has probably considerably diminished in the last thousand years, the tree is undoubtedly much older. Are there older Yew trees known in England? I send a photograph after a sketch. The tree stands in the Valley of Balderschwang, in South Western Bavaria, on a very narrow ridge.—OTTO FORSTER, *Augsburg*.

"**Trees of Liberty**" in Paris.—The last of the "Trees of Liberty" planted in Paris during the Republic of 1848 has just been cut down in the courtyard of a house in the Rue d'Amsterdam, which it had embellished and shaded, if not sanctified, during the last four-and-twenty years. The first "Tree of Liberty" was planted on the 24th of March, 1848, in the Champs de Mars. After the 4th of September, 1870, there was a question of planting new trees of liberty, and some were planted in the provinces; but the scheme fell through in Paris, owing to the high price of fuel.

The Monterey Cypress (*C. macrocarpa*).—I did not say that Mr. Barron had lost 999 out of a 1,000 plants of this Cypress which he had planted near the sea. What I did say was, that although Mr. Barron had been unsuccessful, that was no reason why others should not succeed; for I had seen hundreds of fine examples of this beautiful tree doing well in so many places round the sea-coast. To point out all the places in which I have seen it thriving, from Brighton to the Isle of Wight and from thence to Swansea Bay—would take up too much space. I will therefore only state that I saw some fine healthy plants of it close to Sketty, and, only a few minutes' walk from Mr. Barron's place, near the Oystermouth station, Swansea Bay, and not far from the road leading to the well-known ruins of Oystermouth Castle.—JAMES BARNES.

THE COTTAGER'S GARDEN.

No waxen blossom stained with rainbow hues,
No crimson-flush of petals, heaven-dyed,
No spoils of distant zones and eastern shores,
Snatch'd from the poisonous woods to feed man's pride;
No spiked and spotted aloes, dagger fenced,
No lilies floating on their leafy raft,
No ait-plants dappled like great butterflies,
Spice odours from the Orient isles to waft;
But just one little bush of southernwood,
Fragrant and evergreen as honesty,
And clumps of purple heart's-ease rarely found
In rich man's gardens, whereso'er they be.
A tufted rod of hollyhocks, with rosettes,
For bower-pot or for posy; or a bed
Of blood-red scented cloves, so jagg'd and quaint,
To deck a Sunday coat with tuft of red.
A plant of marigold, with golden glow,
To spread perennial sunshine o'er the plot;
A winter rose, to bloom when summer's gone,
And cast a gleam of hope when spring's forgot.

—All the Year Round.

THE HOUSEHOLD.

THE FAIRY-RING CHAMPIGNON.

(*MARASMIUS OREADES*.)

CHAMPIGNON is a name applied in France to edible fungi in general, or, if specifically, it indicates more especially the common mushroom. The subject of our illustration is an early species, seldom produced in any quantity late in the season. When of a good size, and quickly grown, it is, perhaps, the best of all agarics. It is so common in some districts, that bushels of it may be gathered in a day, and even on our lawns it is by no means uncommon, where, as well as in old pastures, it generally appears in broad brown patches, either circular, or forming a portion of a circle. M. urens, the only species with which it can be confounded, the most acrid of all allied funguses, usually grows in woods, though sometimes in the fairy-ring. However, its flat top and narrow crowded gills cause it to be readily distinguished anywhere.

Pileus smooth, fleshy, convex, subumbonate, generally more or less compressed, tough, coriaceous, elastic, wrinkled; when water-soaked, brown; when dry, of a buff or cream colour, the umbo often remaining red-brown, as if scorched; gills free, distant, ventricose, of the same tint as the pileus, but more pale; stem, equal, solid, twisted, very tough and fibrous, of a pale silky-white colour.

The following are the opinions on the merits of the Fairy-Ring Champignon as an edible fungus:

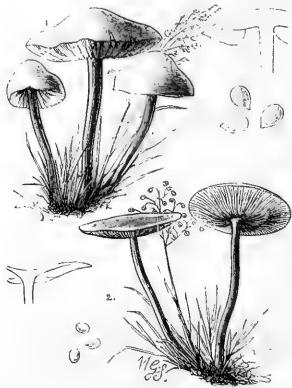

"On the Continent this species has long been considered edible, but, on account of its coriaceous texture, it is dried, and employed in the form of powder, to season various made-dishes."—DR. GREVILLE,

"The common Fairy-Ring Champignon is the best of all our funguses, yet there is scarcely one person in a thousand who dare venture to use it. With common observation no mistake need be made with regard to it. It has an extremely fine flavour, and makes perhaps the very best ketchup that there is."—REV. M. J. BERKLEY.

"An excellent flavour, as good as that of most funguses."—DR. BADHAM.

MODES OF COOKING MARASMIUS OREADES.—GENERAL USE.—"Cut in small pieces and seasoned it makes an excellent addition to stews, hashes, or fried meats, but it should only be added a few minutes before serving, as the aroma is dissipated by over cooking. It is the mushroom used in the French *à la mode* beef shops in London."—DR. BADHAM.

When stewed, the champignons require rather longer time to insure their being perfectly tender. They are readily dried by removing the stems from the fungus, threading them on a string, and hanging them up in a dry airy place. "When dried, it may be kept for years without losing any of its aroma or goodness, which, on the contrary, becomes improved by the process, so as, in fact, to impart more flavour to the dish than would have been imparted by the fresh fungus; though it is not to be denied that the flesh then becomes coriacous (or tough), and less easy of digestion."—DR. BADHAM.

The Fairy Ring Champignon.

CHAMPIGNON POWDER.—Put the champignons in a stew-pan with a little mace, and a few cloves, and a sprinkling of white pepper. Simmer, and shake constantly, to prevent burning, until any liquor that may exude is dried up again. Dry thoroughly in a warm oven until they will easily powder. Put the dried agaric, or the powder, into wide-mouthed glass bottles, and store in a dry place. It will keep any length of time. A tea-spoonful added to any soup, or gravy, or sauce, just before the last boil is given, will produce a very fine mushroom flavour.

PICKLED CHAMPIGNONS.—Collect fresh buttons of the Fairy-Ring agaric, and use them at once. Cut off the stems quite close, and throw each one as you do so into a basin of water in which a spoonful of salt has been put. Drain them from it quickly afterwards, and place them on a soft cloth to dry. For each quart of buttons thus prepared, take nearly a quart of pale white wine vinegar, and add to it a heaped tea-spoonful of salt, half-an-ounce of whole white pepper, an ounce of ginger-root bruised, two large blades of mace, and a fourth of a salt-spoon of cayenne pepper tied in a small piece of muslin. When this pickle boils throw in the agarics, and boil them in it over a clear fire moderately fast, from six to nine minutes. When tolerably tender, put them into warm wide-mouthed bottles, and divide the spicce equally amongst them. When perfectly cold, cork well, or tie skins and paper over them. Store in a dry place, and keep out the frost. Full-sized champignons may be pickled exactly in the same way, but will

require longer boiling, until, indeed, they become tender. *Modified from Miss Acton.*

CHAMPIGNONS QUICKLY PICKLED.—Place the prepared buttons in bottles with a blade of mace, a tea-spoonful of peppercorns, and a tea-spoonful of mustard-seed in each, and cover with the strongest white wine pickling vinegar boiling hot. Cork or tie down as before, but do not expect them to keep above three months.

MODES OF COOKING TRUFFLES.

TRUFFLES AU VIN.—Take some good-sized fresh truffles, wash them perfectly clean, put them in a saucépan with a pod of garlic, a bundle of sweet herbs, and pepper and salt to taste; fill up the saucépan, so as to cover the truffles, with some very good stock and white wine in equal parts. Let them boil gently till done, and serve dry in a napkin.

TRUFFLES À L'ITALIENNE.—Lay some truffles cut in slices in a dish that will stand the fire; stew over them some parsley and shallot finely minced, some pepper, and a little salt; pour some olive oil over them, put them in the oven, covered close, for a quarter of an hour or twenty minutes, and when done squeeze the juice of a lemon over, and serve.

TRUFFLES SAUTÉES.—Put some butter in a saucépan, and some truffles cut in slices; toss them for five minutes, then moisten with a glass of sherry, and add pepper, salt, a little powdered nutmeg, and a small piece of glaze; let them stew gently till done. Serve with sippets of bread fried in butter.

Cauliflower Salad.—Boil a cauliflower in salted water till tender, but not overdone; when cold, cut it up neatly in small sprigs. Beat up together three tablespoomfuls of oil and one tablespoomful of tarragon vinegar, with pepper and salt to taste; rub the dish very slightly with garlic, arrange the pieces of cauliflower on it, strew over them some capers, a little tarragon, chevill, and parsley, all finely minced, and the last bit of dried thyme and marjoram powdered. Pour the oil and vinegar over, and serve.

Orange Salad.—Peel eight oranges alongways, take out all the pulp, and remove every vestige of skin from them, core them as you would core apples, then cut them in slices, and lay them in a deep dish; strew over them plenty of powdered loaf-sugar, then add a large wine-glassful of pale brandy; keep the dish covered close till the time of serving.

Orange Chips.—Cut your oranges longways, take out all the pulp, and put the rinds into rather strong salt and water for six days, then boil them in a large quantity of spring water until they are tender; take them out, and lay them on a hair sieve to drain, then make a thin syrup of fine loaf-sugar (one pound to one quart of water); put in your peels, and boil them over a slow fire till you see the syrup candy about the pan and peels, then take them out and grate fine sugar over them. Lay them on a hair sieve to drain, and set them in a stove, or before the fire to dry. Lemon chips or candied peel may be made in the same way.

THE PROPAGATOR.

THE ART OF GRAFTING.

TREATMENT AFTER GRAFTING BY APPROACH.—The employment of two distinct subjects so as to preserve a harmony of growth necessitates the use of fastenings, supports, props, or hooks, in order to fix the grafted stems and branches as firmly as possible in the desired position. Should the bandage have penetrated the bark, it should be removed, and a fresh one put on if there is reason to think that the union of the parts is not completed. The final detachment of the graft requires the greatest care. It consists in separating the branch or stem which forms the scion from the parent plant as soon as it (the scion) can dispense with its support, and is the last operation in layering and grafting by approach. It comprises two points:—first, cutting off the head of the stock above the graft; second, cutting the scion-branch or stem below the graft. It is prudent to proceed by degrees both in the entire operation and in its details, first cutting off the head of the stock and afterwards detaching the scion from the parent stem. In both cases this should be done by a series of successive cuttings, in order to avoid the reaction consequent on extensive mutilation.

CUTTING OFF THE HEAD OF THE STOCK.—The operations for this purpose may commence a fortnight after grafting, if the graft appears to have succeeded. First, the extremities only of the principal branches are cut off. A week after they are shortened down to four or eight inches. When the union of the graft is certain, the stem is shortened in two or three cuttings, so as to leave a simple stump about two inches above the

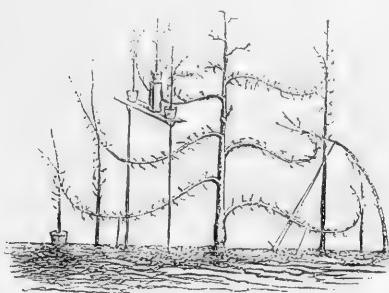

graft, and furnished, if possible, with small shoots to draw the sap. With subjects grafted in spring, this operation is performed about the end of summer; the cohesion of the parts will be perfect before winter. But if the grafting takes place later, we should confine ourselves before winter to shortening the branches of the head or the leading shoot as soon as the parts are perfectly united. The final cutting down to four inches above the graft should be postponed to the following spring, when the sap begins to flow. The heel or stump is retained for one season to serve as a prop to which the scion is tied, and also that the shoots left upon it may draw up the sap. It is cut away entirely when the cohesion of the parts is considered perfect and the scion sufficiently vigorous to dispense with it. It would not be amiss to cover the wound with grafting-wax, and to continue the prop for some time longer. This succession of cuttings is only applicable to those cases of grafting in which the stock has not been previously headed down, and when the part above the graft is to be replaced by the development of the scion.

DETACHMENT OF THE SCION FROM THE PARENT STEM.—This is an important matter, as by it the scion is left to its own resources, the parent stem being no longer called upon to support it. We cannot, therefore, set about this operation with too much circumspection. In the first place, complete separation should not take place until the graft has attained one full season's growth. Some persons do not always observe this rule; but we cannot recommend anyone to follow their example, and the grafter will find our opinion confirmed in the course of his practice. However, the scion should continue connected with the parent as long as its union with the stock is incomplete. The time of perfect cohesion may be judged of by the swelling which rises round the edges of the joining, and by the simultaneous growth of the two parts. In case of doubt, it is best to act prudently and prepare the young tree to support itself without the help of the parent. This is done by making cuttings or incisions on the part which joins the parent to the stock. A single incision may suffice, but at the end of a week or a fortnight it should be made deeper. Instead of single incision, the separation may be gradually effected by a succession of cuttings penetrating the bark and the wood, or of circular incisions or rings on the arm of the graft. These are begun at some distance from the point of contact with the stock, and are made deeper and nearer to the graft at each successive operation. At last the arm is cut clean off close to the graft, and the wound covered with grafting-wax.

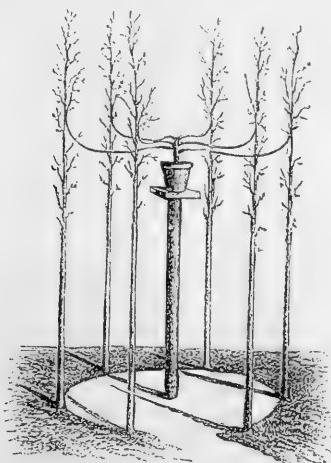

RE-PLANTING.—Should the new tree not find in the place where it has been grafted a sufficient supply of nutritive elements, it should in almost every instance be taken up and transplanted into another place, either in the nursery or where it is intended to stand permanently. It is better not to remove it until it has grown at least a year from the time of its detachment from the parent. It will thus have become inured to exist on its own resources, and will not have been subjected to several severe operations in quick succession. Should the separation have produced any deviation from the desired direction of growth in the grafted tree, a stake or prop should be used, which will keep in a straight line both the stem and the graft at the same time. A few longitudinal incisions on the elbows or curved parts, aid the dilatation of the tissues, the free circulation of the sap, and the straightening of the stem; but trees newly transplanted should not be thus cut.

PROPAGATION BY APPROACH-GRAFTING.—In all cases it is best to have the scion and stock in close proximity to each other, as the work of grafting is thereby simplified. In well-kept nurseries, the parent-trees are planted in positions where grafting by approach is intended to be carried on, either before the stocks are planted, or at the same time. Should parent-trees and stocks, which are strong enough to be grafted at once, be planted, they should not be operated upon for at least a year. They will thus be better rooted, and the union of the graft will be more certain. Those parent-trees and stocks are selected which may be grafted with success, and are trained in a tall or branching form, in order to facilitate their junction at the time of grafting. The same parent may furnish scions to several stocks at the same or different times. The illustration

just given exhibits several methods of placing stocks of various sizes in proximity to a common parent-tree. Here the stock which is high enough is grafted in the upper part with a scion growing at the same elevation, while its neighbour, which is too high for the next scion, must be drawn towards the ground, in order to be brought into contact with it. Another is grafted close to the ground. Among the subjects in pots, some are placed on a simple or double stand, which raises them to the

desired height; another is grafted with the pot buried in the soil, which may answer it better. The stocks being young and the scions sufficiently flexible, they can be brought together in places best suited for grafting them. In nurseries, small samples of new trees are sometimes kept in pots. If it is desired to propagate them on tall stems, stocks of the required height are planted, and the parent-plant is elevated sufficiently by means of a stand. The following representation exhibits a

specimen of this kind of work. In order to protect the parent from the effects of prolonged drought, the pot should be placed inside a larger one, and the space between them filled with moss which should be kept moist, or with fine sand, which is better for keeping cool. An example of a method diametrically opposite to the preceding is very often seen in nurseries, in which the parent-tree is very strong and branching, while the extension of its roots and the shade of its foliage seldom allow young stocks to be planted around it. In order to propagate

it, young stocks must be grown in pots. In the second year of their growth they are placed among the branches of the parent-tree. For this purpose a stage with steps or shelves is erected, on which the stocks are placed within reach of different branches. The pots placed on a shelf are surrounded with a bed of moss, tan, sand, or other material, which will retain a moist coolness; for it will be difficult to water them, and rain and dew will be intercepted by the foliage. When a tree is intended to serve as a parent in grafting by approach, it is well to excite the sap to flow towards the scion-branches, especially at the time of grafting. Accordingly the branches not used for grafting should be lopped or shortened without weakening the tree. This suppression of some of the branches will cause a greater flow of sap to the others, which are to be used as scions. It also enables us to repeat the operation of grafting by approach every year with the same parent-tree. The shoots which are developed by the cutting of the branches which are not grafted, will serve in their turn, should there be need of them, for scions the following season, just when the detachment of the previous year's grafts is commenced.—*C. Ballets, "L'Art de Graftier."*

(To be continued.)

THE SIX OF SPADES.

CHAPTER V.

I REMEMBER that, when we first formed our floral brotherhood, I introduced the name of Joseph Grundy with some anxiety, lest it should not be welcomed as I wished. I was afraid that his occasional wanderings from the garden in the direction of the stable-yard, the sudden transfer of his attentions from his horseshodish to his horse, and again from his cob to his cobnuts, might disqualify him from becoming a member of our little guild of gardeners. These noses, I reasoned, accustomed as they are to Orange-blossoms, will inevitably turn up at the mere notion of a groom with straw at his boots. But those noses did nothing of the kind. My nomination was received with hearty approval. "If he is not too much engaged," said Mr. Oldacres, with a quaint gravity, "in laying out the new grounds at Kensington, or in reviewing 'Darwin on Species,' let us have him by all means. Seriously, I am glad to second this candidate. While we teach him something about gardening, we cannot fail to profit in turn from the presence among us of an industrious, an honest, a righteous man."

To these commendatory epithets, I would append the adjective *cheery*, as characteristic of one who is not only happy himself, but communicative of happiness to others. I never meet that Fourteen Stone of healthfulness, crowned with its rosy smiling face, as bright as a good conscience and brown soap can make it, without feeling a certain freshness at heart—a braver confidence in the hopes and joys of life—a more sure emancipation from its cares and sorrows. Like the "bit of blue" which precedes the sunshine when the storm-clouds break, that face beams with fine weather. Here is a delightful barometer, which disdains the influence of atmosphere, rain, and wind, and boldly assures you in the middle of a hurricane, that everything is "set fair." It is a face at which babies of the most reserved and haughty disposition immediately smile and coo; while the most timid children "walk under his huge legs and peep about, to find themselves dishonourable" lollipops. Coming quickly round a corner, upon a recent occasion, I suddenly confronted Mr. Grundy, engaged in the arduous evolutions of hopscotch, and his expression of bashful uncertainty whether he should resume his position as a rational biped, or go on with the game and win it, was a supreme treat, I can assure you. Finally, he got upon the line—I wonder with those boots of his that he was ever off it—and resumed his original standing in society, amid the derisive cheers of his small competitors.

You would scarcely imagine that this festive countenance could ever be regarded with a qualified pleasure, nay even with feelings of discomfort; but there are scenes and seasons wherein I have met it with much perturbation of spirit. I maintain that upon occasions of national humiliation, upon Ash-Wednesday and other days of penitence, Joseph Grundy ought to sit in the vestry. No member of our congregation is more in earnest than he; but his face utterly declines to

identify itself with any internal seriousness, and glows in its amazing joy and radiance, as though protesting against the whole proceeding, and contradicting every word of the service.

And was not that same hilarious visage a sore trial and stumbling-block, when, in days that are past and a gallery that is pulled down, Joseph Grundy performed on the bassoon? He was but poor company as a musician, was Joe, but thoroughly conscientious; and though I never knew him to finish with the choir, he always played out his verse honourably, and came in a few notes behind, blown, but extremely gratified. We have an harmonium now, and the bold bassoonist sings, and sings well, in the choir. Drowsy indeed must that believer be who does not start in his bed upon Christmas morn, when Grundy, lustily and with a good courage, bids his brother "Christians, awake!"

Lustily, and with a good courage, is his rule in all things. It does one good to see him at his work, and I think of the American's striking words, of "the nobility of labour, the long pedigree of toil," as I watch him, manfully accepting that irksome destiny, which the first gardener hath entailed upon us all. A right honest Spade is Joseph. His no "lubbard labour," of which Cowper, in "The Garden," speaks as "loitering lazily, if not o'erseen." If you come upon him when he is resting awhile, he does not hastily resume his labours, and so confess that he has been idle, and does not deserve relaxation (I always distrust those demonstrative gentlemen who are so excessively energetic when their employer is present), but he stands at ease until he feels himself refreshed, and then plies his spade once more, with a determination and energy which induce the idea that he has solemnly pledged himself to dig to the Antipodes before tea-time. It is good, I say, to watch him at his work, for "laborare est orare" and that work is prayer, is as true a text this day as when it cheered the hearts of those toilsome monks, who were long the only, and always the best, gardeners.

So we, having seen Joe Grundy dig, were glad to admit him into our Society of Spades. He is not scientific, it is true. I recall mistakes in his nomenclature of plants, discreditable to his etymology. I have heard him speak, for instance, of *Yallermandies*, *Cameleons*, *Dolphinimius*, and the like. I know that in spelling *Cactus* he leads off with the letter K.; and I am quite sure that he could no more repeat some of the delightful titles which are given to flowers (let me mention, by way of a nice little specimen, *Siphocampylus Manetticoflorus*) than an Ephraimite could say *Shibboleth*. But there is a nobler language, my friends, than is to be found in Botanical Dictionaries, grand words of Truth, Goodwill, and Honesty; and these Joseph Grundy speaks. There is a higher task appointed than the precise orthography of tallies, that we "learn to labour and to wait;" and he studies this lesson well.

In his little intervals of leisure, the semibreve rests of his solo on the spade, during which, to quote his own expression, he is engaged in "catching his wind," he is wont to survey with much contentment the pleasant garden around him. It refreshes him, he says, to have a peep at the flowers, and to see things looking comfortable and happy, as though they thanked him for his trouble; and, indeed, to look upon that smiling pleasure is a "refreshment to the spirit of man." It is laid out much as gardens were a quarter of a century ago. Large beds, round or oval principally, with flowering trees in the centre, the Lilac, the Acacia, the Laburnum, the Almond, and their kind; next these, the glossy evergreen, the Arbutus, the Aucuba, the Box, the Berberis, the Juniper, Holly, and Yew; and outwardly the border for flowers. "And gravel walks there for meditation," meander about these beds in tortuous course, conducting you to sweet little spots of coolness and seclusion, and giving you a continual change of objects for contemplation. I never wander in those charming grounds, but I ask myself this question—Are we not making a "tremendous sacrifice," (as the drapers say, when they are anxious to dispose of surplus stock, or seedy old "shopkeepers") to that Gigantic Idol called "Bedding Out?" Are not our modern gardens, and these close to our windows, fireworks and kaleidescopes for three months in the year, with brown fallows for the remaining nine? Don't talk to me about your "Winter Gardens," your Golden Hollies with eight leaves your priggish little Irish Yews, about as big as ninepins

To the Nursery, say I, with those tiny infants. And I won't listen to any nonsense about "grand display of bulbs in Spring!" The grand display costs a fortune, and comes up "patchy," after all. I looked out the other morning from the window of a grand house in these parts, where they have streets of glass and regiments of gardeners, upon a magnanimous but unhappy experiment to beautify the beds with bulbs. There were to be Maltese crosses in silver, and golden coronets upon cushions of purple. The idea was gorgeous, but the result was this—I could scarcely shave for laughing! Oh, the gaps and the blanks, the *hiatus valde deflendi!* Puritanical mice had defaced the crosses, and appropriated the Crown Jewels.

Surely it is better for mind and body to feed regularly upon wholesome food, upon the meats and fruits of the earth in their season, than to have three months of feasting, and nine of fast. At the Grange there is always something close at hand, not exiled to the kitchen garden, to please you.

"The daughters of the year

One after one through that still garden pass,
Each garlanded with her peculiar flower."

From the cheerful parlour, with its oaken panels and large square stone-mullioned window, I see in winter the Laurestinus, the bright red berries of the Holly, the pale yellow Aconite, the white Christmas Rose. There are Violets under that window, waiting for a sunny gleam, and the room itself is redolent now with the delicate perfume of the Chimonanthus fragrans. Soon they will have in abundance the Snowdrop (our Lady's flower)—the Crocus, purple, and gold, and white (the latter irreverently termed by children "poached eggs," and very like them)—Hepaticas, the sweet Mezereon, and all the first flowers of spring. You "would remove that Ribes, because it must look shabby in the winter!" But don't you see that there are too many evergreens around it to allow the eye to rest upon it, much less to be offended by it; and it is so with all the deciduous trees.

"And we seem," said Miss Susan to me (two maiden sisters live at the Grange, Miss Susan and Miss Mary Johnstone, so sweet tempered, and good and graceful, that I often wish they were twenty years younger, and bigamy more in favour), "we seem to have all the happiness of a garden without those little vexations and disappointments which trouble some of our neighbours. We ought to be very thankful;" and I know that she is thankful, though she neither groans, nor squints at the firmament, and in fact does not care what I think on the subject; "for our home is not only lovely in our own eyes, but seems to endear itself to our friends also. Even strangers are struck at once with the greenness and quietness of our 'fair ground.' Our good Duke, lunching here in September—it is only in the partridge season that we have the privilege of a visit—looked around, and sighed to himself, 'How very, very peaceful!' He was comparing our pretty little plot, I fancy, with his grand terraces, and his geometrical designs, his rainbows, his ribbons, and his stars, and I verily believed that he preferred the former. Indeed, he confessed as much, by quoting two lines of poetry, which we afterwards found in a translation by Mr. Pope from Martial:—

"But simple Nature's hand with nobler grace
Diffuses artless beauties o'er the place."

And dear Mr. Oldacres, the first time he smoked a pipe in the new arbour, seemed to arrive at a similar conclusion. "Prettier than anything we've got," he grunted. "If a man wants to know what a fool he is, let him go and lay out a garden!"

"And it is a comfort to feel that our old-fashioned style evokes neither jealousies nor comparisons from your anxious modern competitors. If the spirit of any young gardener is troubled at the sight of some to him unknown novelty, and envy with malignant glare is eying it, as Greedy Dick the tartlets and pies, he is at once appeased to hear that it has been with us half a century, and is only annoyed with himself for admiring anything so superannuated. No one points out, with lively satisfaction to himself, those 'sad mistakes in arrangement of colours,' which your great artists are as prompt to see in others as they are to overlook in their own parterres. We are never told that our favourite plants are 'quite super-

seeded, and gone out of cultivation some years since!' And nobody sneers at our boiler, for the simple reason that we have no greenhouse. Ah! I must tell you what dear Mary said" (Miss Susan, you must know, looks upon Miss Mary as a combination of Sydney Smith and Venus), "when Joseph expressed a wish, the other day, that we would set up what he called 'a bit of a Consartive-Tory.' 'Joseph,' she said, 'so far as I am concerned, I feel more disposed, as I'm losing my hair, to set up a bit of a *Wig!*'"

"Apropos of Grundy, what do you think that delightful elephant did last evening? We had a few friends to dine with us, and it unfortunately devolved upon Joseph to place a pyramid of jelly upon the table. Carried unsteadily, it commenced of course a series of the liveliest oscillations, and so swayed itself to and fro, when it reached its destination, that poor Joseph called to it in real agony of mind, 'Who-a who-a, who-a?' I need not tell you that he concluded the performance by hissing violently, when he swept away the crumbs, as though manipulating his horse, for that, you know, he always does."

S. R. H.

(To be continued.)

ASPECTS OF VEGETATION.

THE TRAVELLER'S TREE OF MADAGASCAR.

MADAGASCAR is larger than Great Britain and Ireland combined, and, therefore, as may be imagined, its vegetation, which is of a rich tropical character, varied by tall Cocoa Palms, groves of Pandanus trees, Indian Acacias, thickets of Bamboos, and other forms of hot-country vegetable life, is interesting in the extreme. Its interior is mountainous and wooded, some of the trees being of surprising beauty, and the woods often so loaded with a luxuriant drapery of creepers, as to render them an almost impassable jungle. Parasitical on the branches of some of them have been found Angraecums of the most lovely description, while ground Orchids of other kinds are not uncommon; and Madagascar is said to be the "very Eden of ferns."

In running streams occur the Lace-leaf plant, now so interesting a feature of our stove aquaria; and, in larger rivers, great patches of the beautiful blue Water Lily (*Nymphaea caerulea*).

But it is with the Traveller's Tree (*Urania speciosa*) we wish now more particularly to deal, and whose singular structure and masses of broad foliage impart so peculiar a character to the Madagascar landscape. As our illustration indicates, it is a moisture-loving plant, or rather, tree; but it is also abundant on hillsides, covering vast tracts of the country, intermingled only here and there with the Rofia Palm. Ellis, in his interesting book on Madagascar, thus speaks of this singular tree, which is altogether one of the most remarkable that has been discovered in that island:—

"The extent to which it prevails may be inferred from the native name, 'ravinala,' by which it was designated by Sonorat, its discoverer. Ravinala is, literally, 'leaf of the forest,' as if it was the leaf by which the forest was characterised, which is the fact where it abounds, though in many parts it is not met with at all. The tree rises from the ground with a thick, succulent stem like that of the Plantain, or the larger species of *Strelitzia*, to both of which it bears a strong resemblance. It sends out, from the centre of the stem, long broad leaves like those of the Plantain, only less fragile, and rising, not round the stalk, but in two lines on opposite sides, so that, as the leaves increase, and the lower ones droop at the end or extend horizontally, the tree presents the appearance of a large open fan. When the stem rises ten or twelve feet high, the lower part of the outer covering becomes hard and dry, like the bark of the cocoa-nut tree. Many of the trees in this region were at least thirty feet from the ground to the lowest leaves. I frequently counted from twenty to twenty-four leaves on a single tree, the stalk of each leaf being six or eight feet long, and the broad leaf itself four or six feet more."

"The whole of these twenty-four bright green gigantic leaves, spread out like a fan at the top of a trunk thirty feet

ASPECTS OF VEGETATION.—THE TRAVELLER'S TREE IN MADAGASCAR.

high, presented a spectacle as impressive as it was to me rare and beautiful; and in this part of the country they were the most conspicuous objects for miles together, and were it not that these vast bright green shining leaves are slit on each side by the winds, and so flutter in smaller portions with the passing breeze, the prevalence of this tree would impart a degree of almost inconceivable magnificence to the vegetation of the country.

"In the fan-like head of the Traveller's Tree, there were generally three or four branches of seed pods. The parts of fructification seemed to be enclosed in a tough firm spathe, like that of the cocoa-nut; but the subsequent development was more than that of the fruit of the Plantain. When the pods, or seed vessels, of which there were forty or fifty on each bunch, were ripe, they burst open, and each pod was seen to enclose thirty or more seeds, in shape like a small bean, but enveloped in a fine silky fibre of the most brilliant blue or purple colour.

"But this tree has been most celebrated for containing, even during the most arid season, a large quantity of pure fresh water, supplying to the traveller the place of wells in the desert. Whenever I inquired of the natives, they always affirmed that such was the fact, and that so abundant and pure was the water, that when the men were at work near the trees they did not take the trouble to go to the stream for water, but drew off and drank the water from the tree. Having formerly been somewhat sceptical on this point, I determined to examine some of the trees and during my journey this morning, we stopped near a clump of trees. One of my bearers struck a spear four or five inches deep into the thick firm end of the stalk of the leaf, about six inches above its junction with the trunk, and on drawing it back a stream of pure clear water gushed out, about a quart of which we caught in a pitcher, and all drank of it on the spot. It was cool, clear, and perfectly sweet. On further examination I found that there was no filtration of the water through any part of the plant, as I had been led to suppose when I had seen water drawn by Sir William Hooker from one of the specimens in the palm house at Kew. There was a kind of natural cavity, or cistern, at the base of the stalk of each of the leaves, above its union with the stem, and the water which had been collected on the broad and ribbed surface of the leaf, had flowed down a groove or sprout on the upper side of the stalk, into this natural reservoir, whence it supplied nutriment to the tree, and refreshed to the traveller or the labourer.

"But in Madagascar this tree might, with propriety, be called the Builder's Tree, rather than the Traveller's Tree. Its leaves form the thatch of the houses on the eastern side of the island. The stems of its leaves form the partitions, and often sides of the houses, and the hard outside bark is stripped from the inner and soft part, and, having been beaten out flat, is laid for flooring; and I have seen the entire floor of a long, well-built house covered with its bark, each piece being at least eighteen inches wide, and twenty or thirty feet long. The leaf, when green, is used as a wrapper for packages, and keeps out the rain. Large quantities are also sold every morning in the markets, as it serves the purpose of table-cloth, dishes, and plates at meals, and, folded into certain forms, is used instead of spoons and drinking vessels."

In warm conservatories planted in the natural style, the Traveller's Tree, in skilful hands, might be made to play an important part, especially in the neighbourhood of artificial water, in which its reflected form would have a striking and pretty effect. If only for the sake of contrast this truly Banana-like plant is well worth attention. It is occasionally to be found in our hot-houses; but not unfrequently *Strelitzia augusta*, which it somewhat resembles in habit, goes under that name.

Washington Irving as a Garden Critic.—"I was once taken down with him," says the author of "Pencillings by the Way," "into the country by a merchant to dinner. Our friend stopped his carriage at the gate of his park, and asked us if we would walk through his grounds to the house. Irving refused, and held me down by the coat, so that we drove on to the house together, leaving our host to follow on foot. 'I make it a principle,' said Irving, 'never to walk with a man through his own grounds. I have no idea of praising a thing whether I like it or not. You and I will do them to-morrow morning by ourselves.'

THE KITCHEN GARDEN.

A SPARAGUS CULTURE.

BY R. GILBERT, BURGHLEY.

The best soil for Asparagus is a light, rich, friable loam. Towards the end of autumn or beginning of winter select an open situation for its growth. Having judiciously done this, give the ground a thick coat of farmyard manure, say at the rate of sixty loads per acre. Then trench to the depth of three feet, thoroughly mixing the soil and manure, and lay it up in ridges and let it remain in that condition throughout the winter to ameliorate and sweeten.

SEED SOWING.

Asparagus seed should only be gathered from the strongest and earliest shoots, such as have had the full benefit of light and air during the summer. The bed should be light, rich, and sandy, loam mould affording the principal source of nourishment. Sow the seed in March or early in April, and if the beds are carefully hoed and kept free from weeds during the summer and autumn, the plants will become strong and be in good condition for planting the following spring.

PLANTING.

The ground having been trenched and neatly levelled, set out the beds as nearly north and south as possible, five feet wide, with two-feet alleys between them. Plant three rows in each bed, which may be done by setting the line a foot from the outside along the beds, and making a notch or drill with the spade sufficiently deep and wide to allow the roots to be carefully spread out. While the drills are open, scatter into and along them some clean river sand to sharpen the soil and enable the rootlets at once to commence work; this done, fill up, and make all firm about the plants with the hands, keeping the crowns two inches below the surface. The other two lines must be planted in the same manner, and should stand eighteen inches apart. Planting should not be commenced until the roots begin to grow; about the first or middle of April is the usual time.

GENERAL MANAGEMENT.

Throughout the summer and autumn the beds must be kept open and clean by means of frequent hockings, say once a fortnight. Should the weather prove very dry after planting, a mulching of litter or other dung would greatly benefit the plants. During the first and second seasons cauliflower may be planted between the beds. Cutting should not begin before the third season, and even then it must not be indulged in too severely. The third season the beds should be earthed over from the alleys, which are dug out to the depth of eighteen inches, the soil therefrom being laid on the surface of the beds for blanching purposes.

FORCING.

Our mode of forcing Asparagus is clearly illustrated by the annexed diagram. Our beds are five feet wide, with three-feet alleys between them. The alleys are dug out to the depth of

Section of two Beds with Alley between them, and half of two corresponding Alleys.

two feet, the soil being spread over the surface of the beds, on which frames, covered with sashes, boards, or shutters, are placed. The space between the beds, being four and a half a foot deep and three feet wide, is filled with fermenting material, such as stable dung and leaves, as are also the outside half alleys. Before filling these spaces with litter, we make holes into the sides of the beds large enough to admit a one-inch bore drain pipe. These holes we find beneficial in admitting heat to the interior of the bed. The side trenches are filled with hot dung to the height of the frames, the beds in which, marked A, are also covered with the same

material until the heads make their appearance, when it is removed. If white Asparagus is wanted, the frames are kept dark by being covered with shutters; but, if green is preferred, glazed lights should be put on. After the fermenting material is removed from the beds, the frames are kept close for a few days, after which a little air is given on favourable occasions, a practice which increases both flavour and quality. It is necessary to maintain a temperature of 60° or 65°, but at no time should it exceed 70°. When this heat cannot be kept up, fresh linings must be added. The ordinary plan of forcing Asparagus is by lifting good four-year old roots, and placing them thickly on a hotbed. This is more uncertain than forcing the plants where they grow, inasmuch as the bed may become overheated, which would be prejudicial to the plants. On the surface of the bed should be placed a few inches of old tan, on which the plants are to be thickly stored, carefully spreading out their roots. Some fine soil must then be worked among them. Sashes or wooden shutters may then be placed on the frames, which are kept quite dark till the plants appear, after which, should the produce be required in a green state, light and air may be given in suitable weather.

HORSERADISH.

MR. THURSTON says (see page 112) that he selects roots of Horseradish "as long and as straight as possible," and that by the system he lays down he has grown in one year a stick of Horseradish twenty inches long and six inches round, from a very slender root. I have adopted this system for some years, and I can quite vouch for the practicability of obtaining the stated circumference from a very slender root; but will Mr. Thurston kindly point out to us amateurs how the length is obtained, because my own experience is, that to produce a length of twenty inches, the root as originally inserted in the ground must have been twenty inches; for I have never found a root inserted increase in length. It throws out roots from its base and makes for itself a crown, but it will not grow any longer. If, therefore, Mr. Thurston will explain this point, it will be a boon to us, as we should then know if it were indispensable or not to have long roots. I would also remark that I have done all he says in the way of making the bed in March instead of November. What is his experience on that point? The root has always been an awkward one to keep within limits, but by Mr. Thurston's plan it can always be confined to two beds planted alternately, small or large, according to the requirements of a household.

H. S. WATSON.

The Cottage, Old Charlton.

THE KITCHEN GARDEN FOR MARCH.

BY JAMES BARNES.

A most interesting and busy season has now arrived, and one on which the year's success, or otherwise, to a great extent, depends; for if matters having reference to cropping are not systematically performed in proper time, when the soil is in the right condition to receive the plants or seeds, little else but failure need be expected. In matters of cropping, do not stick to any certain rule as to the day of sowing or planting, whether the soil and weather are suitable or not, but first make a good and kindly preparation, by thorough deep culture and turning over of the soil in as rough and open a manner as possible to admit sun and air. In short, turn and re-turn the soil till it falls to pieces like slaked lime, and is in every way so sweetened and pulverised that, by watching the opportunity for a fine day, a large portion of work may be performed. Having all things in order and in good condition is the very keystone of success. It is even better to be a little out of season, than to begin cropping in the midst of disorder.

Artichokes, Jerusalem, finish planting.

Artichokes, Globe, pull away decayed leaves if any, in order to admit air to the stools and crowns, and set about early thinning out the weakest shoots.

Asparagus, continue to get into gentle heat strong roots; sow seed, and prepare for planting new beds the end of the month. I always like to see the buds pushing forth before I take up the plants; after which, do not allow them to lie about, but replant at once in rows two feet apart, and let the plants stand one foot asunder in the rows. A good deep drill drawn on each side of the line, and the roots spread astride of the drill, will be the right way to plant them, and after two years' time, every other row will furnish rare plants to take up for forcing.

Beer, red, sow for salad use for the whole year, and a small portion

of white sugar beet, for use in place of spinach—should it be dry and hot in July and August, when spinach is hard to be got.

Beans: of these, plant a full successional crop of Long-pod, Broad Windsor, or some other approved kind.

Broccoli: of all favourite late kinds sow after the 12th instant.

Brussels Sprouts: of these, make a full sowing the beginning of this month; prick out, and plant early, in order to insure large, seasoned, well ripened plants by autumn, so as to have good solid little heads all up the stems; young, free-growing, late-sown plants will not button or head in to be depended on; a hard-trodden, heavy soil suits them best.

Cabbage, sow a small quantity of the Matchless, Nonpareil, Little Pixie, and London Colewort.

Capiscum and Chilis, pot off; place in moderate bottom heat, and stop at eight or nine inches.

Cauliflower, plant out now a full crop of winter stored plants; sow Veitch's Giant and other late kinds, and prick off, as soon as they can be handled, all early sown plants, first in boxes or frames, then on warm borders.

Carrots: of these, sow a full crop on some open quarters, from the middle to the end of the month, in drills one foot apart, using fresh slaked lime as a dressing. There is nothing with which I am acquainted that insures so heavy or such a clean, finely-flavoured carrot as a good dressing of freshly-slaked lime and a slight dredging of dry chimney soot, applied in showery weather in May.

Celery, sow a pinch in succession; but I never succeeded so well in the way of obtaining a splendid crisp, solid, lasting crop as when I sowed the first week in April, on a gentle bottom heat, thinly prickling out again on some gentle hot-bed. In this way some of the plants are soon ready for early planting out; a batch is then pricked out on half-decayed leaf mould or rotten dung, which can be easily removed with the roots in the form of good balls. In this way no check takes place, and the result is most satisfactory.

Chervil: of this, sow a pinch of curled, first in a warm situation, and, for succession, in a fortnight, on a north aspect, on account of its starting propensities in hot weather.

Cress, &c., sow common and curled, as well as mustard, on a warm border out of doors; and land cress on a north border for summer and autumn use. Of Watercress make new plantings in shallow streams or damp, cold spots, for summer and autumn use.

Lettuces, plant out a full crop, and sow, once a fortnight, a pinch of summer kinds, both cabbage and cos.

Onions, sow a full crop in drills, one foot apart, on well-prepared, thoroughly pulverised soil; if light, make it firm by treading or hard rolling.

Marrow, Vegetable, sow in a little heat, in order to have sturdy, strong plants for turning out under hand-glasses when four or five weeks old.

Sweet and other herbs: sow in a gentle heat Basil and Marjoram, and on healthy borders, Thyme, Winter Savory, Marigold, Purslane, Parsley, in full crop, Skirret, Hyssop, Fennel, Caraway, Borage, Balm, Burnet, &c.

Radicishes, of all kinds sow a full crop.

Rhubarb: seed of this should now be sown, and large crowded roots divided, to make new plantations.

Parsnips, sow a full crop in drills, one foot apart, on deeply-trenched, pulverised land.

Pea, sow throughout this month on well-trenched, deeply-tilted, thoroughly pulverised soil, all the late kinds and tints, the tall sorts, twelve to fourteen feet apart; which is not only a convenient distance, but insures a full supply of light and air to the crop, which is doubled by this treatment; and it forms a partial shade for such summer crops as are planted between the rows. Champion of England, Dixon's Favourite, Harrison's Glory, Laxton's Prolific and Quality, Maclean's Best of All, Prince of Wales, Wonderful, Nonpareil, and Veitch's Perfection are all good peas for succession; and for the last or latest crop of all, British Queen, Premier, and No Plus Ultra. Early peas, stick and protect against cutting winds, and dredge with dry dust the base of all crops now up on dry evenings, to prevent canker and shanking.

Savorys, sow a full crop the beginning of this month, then again at the end of it.

Salsify, sow in drills one foot apart.

Scorzonera, sow after the middle of the month.

Seakale, sow in drills, or dibble one foot apart each way, in order to have strong plants for forcing next winter; if sown on well-prepared, pulverised, rich soil, and well attended to through the summer, strong clear plants will be the result.

Spinach, sow the round summer variety in drills, between peas or other ways, once a fortnight. New Zealand spinach sow in heat.

Turnips, sow in drills a few once a fortnight of any small, short topped early kind, in order to have turnips young, sweet, and tender.

NOTES.

THE TEMPLE GARDEN PLANTING.

It would be difficult to find anywhere a more striking illustration of the little knowledge or love of trees possessed by those who lay out gardens, than is now to be seen in the Temple Gardens. A long and noble promenade has been made just within the garden and parallel with the Thames Embankment, which, as everybody knows, is planted with two lines of plane trees. The walk in the Temple Gardens is very close to the north footway of the Embankment and its line of trees. One would suppose that in the selection of the trees for margining the new promenade, some other kinds than the plane would be selected, and that even a contractor's navy would hesitate to plant another line of the same kind of tree right against those already in position. Not so. A line of planes is planted almost right against the planes of the Embankment, so that both lines must meet and injure each other before the trees are one-fourth grown. Then there is a curved walk leading from the promenade to the buildings, and this again is being planted with planes on each side a few feet from the margin; their tops will touch in a few years! There are at least twenty other trees that would thrive quite well as the plane, and which differ in size, so that subjects suitable for every position might have been easily found. Not one of these is to be seen. There is no evidence that the planters know any tree but the plane; and that, as we have pointed out, is so placed that they seem to have no idea of the size to which it attains. What a pity it is that such a noble and interesting old garden should be spoiled by such silly blundering!

NOT FOR OUR HEIRS.

WHILE the trees on the Embankment, as referred to in a previous number, have been mutilated by "roughism," the young trees planted a few years ago in the churchyard of St. Mary-le-Strand have just been dug up by the roots to gratify the sight-seeing section of the London public by making way for the erection of stands for viewing the procession to St. Paul's. However laudable may be the anxiety to catch a glimpse of the Queen on such an occasion, it would seem to be carrying the desire to do so too far when a permanent injury is recklessly inflicted in order to gratify it. We may be told that at this time of the year young trees may be dug up with impunity if planted again within a reasonable time. But it is self-evident that the digging up of the trees in question, which had already made considerable progress, will be a severe check to their growth, especially as it is already late for tree planting work. It is, indeed, a question whether it would not be better to plant in their places other young trees fresh from the country instead of replanting those which have been necessarily somewhat enfeebled in constitution by the atmosphere of London, which will have rendered them somewhat less able to bear such knocking about as a summary uprooting must involve. If such a course should be deemed advisable, when the time comes for replacing the ill-used trees, the end will be that we shall have to wait a few years longer for the agreeable effect of a few fine trees in mid-Strand, and all for nothing better than the gaining of a few shillings by hiring stands and seats to sight hunters. H.

MUTILATION OF TREES IN HYDE PARK.

EVEN Mr. Vernon Harcourt himself, on gazing at the destruction of trees in the park last Tuesday between the Marble Arch and Grosvenor Gate, must in his own heart admit that the Magna Charta might with propriety be so far modified as to protect timber from the violence of a heedless mob. If it is quite impossible without an infringement of our constitutional liberties to lay down and enforce such stringent regulations as will be sufficient for the purpose, it surely might be allowable to fence in the trees in the park in such a manner as to render them safe from injury. It will take many years to restore to them all they have lost by one day's rejoicing, and the ghost of Evelyn must have smiled bitterly at the anniversary of his death being marked by the wholesale destruction of trees from no other motive than idle mischief. Not even Peter the Great, when he damaged Evelyn's trees at Sayes Court, Deptford, to the extent of £150 in three weeks, committed a greater act of barbarism than that committed by the playful crowd who amused themselves last Tuesday by destroying their own property and leaving the park in much the same condition as though a whirlwind had passed over it. It is always expected that the people as they grow wiser will learn that no particular end is gained by mutilating timber. As, however, their wisdom on this point seems to linger on the road, it might be as well, pending its arrival, to devise some measure that will be effectual to shield them from the consequences of their own folly, and prevent pulling their playthings to pieces.—*Pall Mall Gazette*.

THE NEW GARDEN AT STEPNEY.

THIS, described by the *Metropolitan* as likely to prove "one of the best of the public gardens of London," is a narrow strip of ground about a quarter of a mile long, and from thirteen to eighteen yards broad. It was lately an unenclosed space, with a few elms and other common trees, but is now surrounded by a strong railing, and is being rapidly converted into a garden. Roads cross it in three places, throwing it into four divisions. Although the sides of each strip are as straight as the sides of Gower Street, and although no curvature of the walk through the centre of each slip could neutralise the formality of the scene, a serpentine walk has been made through all the strips; otherwise the works in progress are very satisfactory. If properly planted with a good variety of deciduous trees, the garden will prove a great addition to its immediate neighbourhood, but it can never lay claim to be called "one of the best public gardens in London."

Blackheath.—A correspondent of the *Standard* says, "Blackheath is doomed! It is no longer a free but a conquered spot. All rights of commons are extinguished, and all industries and sports are for the future to be pursued on sufferance. What does Blackheath want with enclosures for flowers, &c.? A wall only stands between it and the grand old historic park, where, on soft lawns, raised enclosures for shrubs and flowers are tastefully in place. But the heath, with its old and wild traditions, and whose glory has been its untrammeled freedom, winces at the exotic plan. The blots on the heath are the work of cupidity (surely not of the lords of the manor). Excavations for gravel and encroaching structures mar the fair proportions of the heath. Why not give compensation for the houses, pull them down, place seats, and plant flowers here? Then the Board of Works might look for praise. There is the plateau on which the cannons and the flagstaff stand. Here, it is asserted, that no fewer than seven currents of air meet together. Here, too, when the wind blows from the south it is arreved, you can taste salt spray on your lips as it bounds over the "purple rim" of the hills. The Knockholme Beeches, plainly described, link us to the sea, for they are a beacon to sailors on the other side. We look on the range which sweeps away to Dover, crowned on its way by Lympne Castle, Caesar's Camp, and Shakespeare's Cliff. Am I sure that this plateau will not be desecrated by enclosure?"

The Albert Memorial in Kensington Gardens.—The Albert Memorial, it is said, will be inaugurated by the Queen in April next. The memorial in itself may be said to be finished, and even now the iron railings are being erected round it. Mr. Foley cannot, however, complete the statue of the late Prince Consort until many months have passed, and if the memorial is inaugurated this spring it will lose its chief charm—it will be "Hamlet" without the Prince of Denmark.

Asphalte Roadways.—The Corporation of London have given instructions for Princess Street, Mansion House, to be laid with asphalte, by the Montreotier Asphalte Company, on a sub-stratum of concrete, made with the natural hydraulic cement from Lyme Regis. The enormous traffic in this part of London will prove a crucial test for roadways executed in the manner proposed.—*BUILDER*.

A Noble Offer.—The people of Aspatria, in Cumberland, want a new market hall and assembly room; and have resolved that the sum of two guineas be offered as a premium for the best plan of a building.

St. Paul's Churchyard.—A project is before the City authorities for widening the western end of St. Paul's Churchyard by cutting off a portion of the ground attached to St. Paul's. The Commissioners have since offered the Dean and Chapter £15,000 for the ground sought to be taken away from the graveyard at the western end, with a view to the proposed improvement there, and the cathedral authorities and the Commissioners are now in negotiation on the subject.

The Lamp Standards on the Embankment.—These have been designed by Mr. Vulliamy, and are to cost, we understand, £21 each. They are good specimens of iron casting, in very bold relief. The arms and lanterns are to cost £13 each, fixed complete, and this, with about £1 each extra for some little necessary adjuncts, gives the total cost of each lamp, fixed and ready for lighting, as £35.

"The Irish Gardener's Record."—We are happy to announce the re-appearance of this useful little publication, which is for the future to be issued fortnightly.

LAW NOTES.

Moving Vines at Expiration of Tenancy.—I have some young vines planted in a small viney়ard, which I am desirous of moving when I quit the premises now I occupy next quarter day; but my landlord claims them as his. Can he legally do so?—H.—[When you quit possession your vines are, we believe, the property of your landlord, and you cannot claim any compensation, unless you are a market gardener, or there is some special covenant in your lease.]

New Park at Tooting.—A lawsuit of an unusual kind got into the Vice-Chancellor's Court the other day, the object of which was to restrain the Metropolitan Board of Works from promoting a scheme under the Metropolitan Commons Act, 1866, for devoting Tooting Beck Common to the public as a park or pleasure ground, the objection to the scheme in question being that it was intended to sell a part of the common for building ground. In July 1868, the owners of the manor of Tooting Beck agreed with Mr. Drew and Mr. Flower to sell the greater part of the manor to these gentlemen to enable them to convert the common into public pleasure grounds. The plaintiff, a Mr. Telfer, was entitled to 1/24th of the manor under the agreement in question, provided that no part of the waste should be sold or let without the consent of the plaintiff and some of his co-owners, and if the common were not used for the purpose intended one twenty-fourth should be resold to him. The contract was completed, and the Metropolitan Board of Works agreed to buy the common from Messrs. Drew and Flower, and induced the Inclosure Commissioners to prepare the scheme, which was objected to. The Vice-Chancellor was of opinion that the Metropolitan Board, standing as they did in the shoes of those persons from whom they had bought, by promoting this scheme were acting in contravention of rights they had contracted to observe. It had been contended that the defendants were acting in a matter of public duty, and therefore they, as a public body, could not be restrained from such promotion. The scheme itself showed that their object in separating a part of the common was to make money, and "there was no trace of anything like an application to Parliament. The injunction, therefore, must issue.

Overhanging Boughs.—My neighbour's trees so overhang my garden as to injure it by their shade. Can I remove the overhanging boughs?—J. F.—[We believe that if a person's trees overhang your garden and fence, to their injury, and the owner of the trees will not cut them back as far as your hedge, you can do it yourself, if you stand on your property. But neighbours should not so act to each other. It is far better to prune by consent.]

Royal Horticultural Society's Show at Birmingham.—It will have been noticed that a resolution was passed at the public meeting, requesting the local committee to give their attention in a special manner to the exhibition of horticultural implements, buildings, &c. If the special prize committee should have ample funds at their disposal, it would be advisable to open a few classes in which prizes should be offered to manufacturers only of some of the leading articles, for example, lawn mowers, garden rollers, garden engines, garden seats, vases for different purposes, flower pots, ornamental and otherwise, collections of spades, forks, hoes, &c. In addition to these prizes, the judges might visit the stands of all other exhibitors, and distribute prizes to articles of merit not included in these classes.—H.

Royal Horticultural Society's Birmingham Meeting.—I see there is to be one class for four pines at this exhibition. Now, the majority of pine growers have not four pines ripe at one time; therefore all small cultivators are shut out; and we get perhaps two, seldom three, exhibitors for one of the best prizes, whereas if for single fruit we should have twenty. The next is for four dishes of grapes. Who beside a market gardener would cut twelve bunches of his best grapes to be spoiled at Birmingham? therefore all the "little men" are again shut out. Next come eight dishes of fruit, a class in which everybody knows few can exhibit. Lastly, what have we poor cabbage-growers done that these most useful products of the garden should not be represented? Had I belonged to the sub-committee (and I was invited to join it), I should have tried my utmost to make classes so that great and small cultivators might meet in the exhibition tent on equal terms, instead of making laws to shut out a deserving, hard-working, and intelligent class of men.—R. GILBERT, *Buryghley*.

Leicestershire Floral and Horticultural Society.—The summer show of this society will be held on Wednesday and Thursday the 3rd and 4th July. It is also in contemplation to hold a Chrysanthemum and winter fruit show some time in November.

Warming Greenhouses with Gas.—I have completed an improved system of gas arrangement, and for several weeks past I have used the gas to warm my greenhouse, which is twenty-five feet long, thirteen feet wide in middle, and twelve feet high; part span. The arrangement outside of the house is an improved air and gas burner acting on a conical double jacket copper boiler with ordinary two-inch flow and return joints, and four-inch iron pipes inside greenhouse. When once lighted the gas continues to burn day and night without further attention or labour. The cost of the gas used is about one shilling per day. (The price of gas here is 5s. per 1,000).—James Copcutt, Aylesbury, in "*English Mechanic*."

THE MANGROVE (RHIZOPHORA MANGEL).

The note (p. 293) from the Royal Botanic Society's proceedings in reference to this plant is not quite correct. A case of mangroves was sent to Kew by Mr. Prestoe, of Trinidad, in 1868 or early in 1869. Though most of them died on being shifted, one lived, which, as well as one received from the Royal Botanic Society, grew well until one night in the winter of 1870-71 the house in which they stood was allowed to get as low as 48°, and after that they drooped, and died in less than a month. The mangrove naturally inhabits muddy swamps close to the sea shore in tropical climates; therefore, when the plants of it just alluded to came to Kew, they were treated to salt water for a time; but after a few weeks this was exchanged for common soft water—in which they were plunged in a tank half way up the pots, and this, together with strong soil induced them to make vigorous growth and to push strong roots from the stems. After that they were transferred to the tank in the Victoria House, where they passed part of each day with the pots submerged, and part just above water. This pseudo-tidal action, however, did not benefit them; for although they continued to grow, they lost vigour. Mangroves will grow quite freely in a temperature above 60°, if the soil is kept wet. J. CROUCHER.

NOTICES TO CORRESPONDENTS.

TORQUAY.—The tenderer kinds of evergreen oaks from Asia will doubtless live out of doors in Devonshire. One of the kinds you have sent is certainly not an oak; another no doubt is *Quercus dealbata* or *glauca*, a Chinese species. If you will send us fair specimens of the others we will endeavour to name them.

H. S. N.—Through Vilmorin, Andrioux, & Co., 4, Quai de la Megisserie, Paris.

J. R.—1. THE GARDEN is the work referred to under another name, and modified in plan. 2. We cannot recommend tradesmen; see trade catalogues. 3. Will be answered next week in "Indoor Garden."

C. B.—The narrow leaved *Eucalyptus* is *resinifera*; and for all medical purposes the resin is said to be fully as efficacious as *knio*; this kind is sometimes called *gummiifera*. The broad leaved one is *Eucalyptus robusta*, a very hardy and rapid growing kind, which attains to an enormous size in Van Dieman's Land.

F. M. H.—W. Thompson, Ipswich.

J. K.—*Lycopodium denticulatum* will succeed in a temperature of between 40° and 50°.

I. O.—We are unacquainted with the stove you name.

M. W.—For red, pink, or purple dwarf edgings to continue in flower till September, we know nothing better than verbenas, nicely pegged down and kept in order.

YOUNG GARDENER.—Use good one-year old vines, and as your fruit wall is an arches plant inside, spreading out the roots well in all directions. Train one rod up each rafter, and, when established, prune on the spur system. Peaches and plums do not succeed well in the same house.

COVENT GARDEN MARKET.—March 2nd.

Flowers.—These continue to be supplied in great abundance and variety, especially such things as Primroses, Cyclamen, Geraniums, and Orchids, among which some charming kinds are furnished in a cut state. Solanums and other berry-bearing plants may also still be obtained.

Prices of Fruit.—Apples, Dessert, 2s. to 4s. per dozen.—Cobs, per 100lbs. 6s. to 6s.—Fibberts, per lb., 8d. to 10d.—Grapes, per lb., 8s. to 10s.—Lemons, per 100, 7s. to 10s.—Oranges, per 100, 6s. to 10s.—Pears, per dozen, 3s. to 5s.—Pine-apples, per lb., 6s. to 10s.

Prices of Vegetables.—Artichokes, green, each, 6d. to 8d.—Asparagus, per 100, 8s. to 10s.—Beet, per dozen, 1s. to 2s.—Broccoli, purple, per bundle, 10d. to 1s. 3d.—Brussels Sprouts, per half sieve, 2s. 6d. to 3s. 6d.—Cabbages, per dozen, 10d. to 1s. 3d.—Carrots, per bunch, 5d. to 7d.—Cauliflowers, per dozen, 2s. to 6s.—Celery, per bundle, 1s. to 2s.—Chillies, per 100, 1s. 6d. to 2s.—Cucumbers, each, 1s. 6d. to 3s.—French Beans, new, per 100, 3s. to 4s.—Herbs, per bunch, 2d. to 4d.—Lettuces (French), Cabbage, per dozen, 1s. to 2s.—Leeks, per bunch, 2d. to 4d.—Lettuces (French), Cabbage, per dozen, 1s. to 2s.—Onions, per bunch, 4d. to 6d.—Parsley, per bunch, 2d. to 4d.—Radishes, per bunch, 1s. to 1s. 6d.—Rhubarb, per bundle, 6d. to 1s. 6d.—Salsify, per bundle, 1s. to 1s. 6d.—Scorzonera, per bundle, 9d. to 1s. 3d.—Seakale, per punnet, 1s. to 2s.—Shallots, per lb., 8d.—Spinach, per bushel, 3s. to 4s.—Tomatoes, per small punnet, 3s.

Readers who may find it difficult to procure THE GARDEN regularly through the newsagents, may have the numbers sent direct from the office, at 19s. 6d. per annum. 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsagents, at the railway book-stalls, and from the office.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same address.

"This is an art
Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—Shakespeare.

PUBLIC GARDENS.

PARKS AND BUILDING GROUND.

No one can be more desirous than myself that parks, gardens, and open spaces should be multiplied in the vicinity of all our large towns, and that they should be made as extensive as possible; but certain considerations, left entirely out of sight in the article on Victoria Park in your last week's issue, seem to render it advisable, with the view of furthering this very object, that the strips of land in dispute should, as originally proposed, be let for building on. With your permission, I will briefly state what these considerations are.

1. When a sum of public money is voted for a park, and a special provision is made to enable the park to become in time self-supporting, and even to have a surplus revenue which may eventually pay back to the nation its original cost, it seems to me to be bad policy to endeavour to annul these provisions, and thus make it a perpetual charge on the revenue. For, if this is done, it must inevitably render any Government both less willing and less able to entertain the question of establishing new parks. The fact of the great increase of population round the park, which is adduced as an argument for keeping the building land open, is the very circumstance which has rendered the surrounding land so valuable, and which will enable it to produce the required revenue.

2. There is, however, a very important principle involved in this question, which has been strongly advocated by Mr. John Stuart Mill, viz.:—that as much as possible of the increase in the value of land which is directly caused by the public, should belong to the public. Now there is no more certain way of increasing the value of the surrounding land than by making a beautiful park in a densely peopled district; and by reserving a strip of land all round that park at the outset, *expressly to be built upon when the demand arises for it*, you do actually secure a large share of the increased value to the public. The strip of building land around Victoria Park, for instance, is certain to increase in value; so that, besides producing a good revenue for the first term of the leases, it will probably, as those leases fall in, be relet at a much higher rate, and so produce an increasing revenue, which may not only suffice to pay for the present park, but may also supply funds towards the formation of new parks in outlying districts where they will be then more needed.

3. But if the strips of land in question are now permanently attached to the park, we not only lose all this present and prospective benefit ourselves, but we make a free gift of the wealth we have created to men who have no earthly right to it. For there will then be a most valuable building frontage to the park, about three miles in extent, in the hands of private persons, whose property will rise to double or treble its previous value the moment we extend the park up to their boundary, and give them the certainty of a perpetual view over it. Many of these freeholders will have purchased their ground at a low price, because it was believed that they would be entirely shut out from the park by a continuous line of houses on the reserved land.

4. It is of the very first importance to establish the practicability of the principle of always securing, at the time when great improvements are first made at public expense, an additional tract of cheap land, the enhanced value of which, created by the improvement, may at some future time repay its cost; and I cannot but think that it is very short-sighted

policy, under *any* circumstances, to claim this reserved land, and so neutralise this highly desirable result. It is almost as suicidal as the practice of those Governments which, having obtained a loan on the faith of the establishment of a sinking fund, appropriate the revenues set apart for that purpose on the first monetary pressure.

5. On looking at your very clear map of Victoria Park, it is easily seen that the strips in question form a very small part of the whole; and although twenty-nine acres in one lump is a good-sized piece of land, it is of far less importance when in a strip nearly three miles long. For a large portion of this extent, the strips are only one hundred feet wide; and it cannot much affect the park as a place of recreation whether the houses, which will soon inevitably encircle it, are built on the outer or the inner side of the surrounding roads. On the other hand, it is a matter of the highest importance to prove, that in populous districts parks can be made self-supporting, after a few years, by the simple method of surrounding them with a belt of land reserved for building, the constantly increasing rents of which shall benefit the public instead of private landowners. I therefore maintain that it is the true interest of the people at large that the original scheme should be carried into effect, because it is founded on a true and most important principle, which will favour (as surely as the opposite course will check) the multiplication of parks and gardens for the people.

ALFRED R. WALLACE.

[We wholly agree with our correspondent, who puts this case in such a clear light. Apart from the various excellent reasons given by Mr. Wallace, it is desirable that the public should possess the power of determining what kind of buildings shall exist in the immediate neighbourhood of its parks. Again, the gain of a mere riband of ground, such as is shown in our plan, or the gain of the strips of ground around the two most recent London parks, and of which we have heard so much clamour, is as nothing compared with the advantage of securing other parks, however small, in densely populated parts of the City, and which we could secure so easily if the grand principle of allowing the public to benefit by the improvements be adopted. We must secure for the dwellers in our vast cities more than a breath of fresh air on a Sunday afternoon at perhaps a distance of several miles from their houses. With reference to the gain to the public from the construction of parks, we have some evidence from the other side of the Atlantic, which came to hand the same day as Mr. Wallace's letter. It is a report of the splendid new park at Brooklyn, which we had the pleasure of visiting in 1870:—"On reference to the rolls of the city's property, the commissioners find that since the commencement of active operations on the park, there has been added to the tax list the large amount of 77,232,410 dollars, the Board of Assessors having felt themselves justified by its very obvious increase, in adding twenty-five per cent. to the city's taxable property for the year 1869. It should be observed, also, in order to a proper appreciation of these facts, that a large portion of this increase, to wit: the sum of 32,820,059 dollars, has arisen in the wards immediately surrounding the park, including the town of Flatbush, thereby increasing the city's annual income nearly a million of dollars."]

THE ROYAL GARDENS, KEW.

Your correspondent's remarks (p. 217) on the Pagoda Vista at Kew will surprise nobody; it is a legitimate subject for criticism to all interested in ornamental planting. How anyone could have dreamed of disfiguring such a beautiful vista by planting deciduous trees in front of Deodars, has caused much discussion amongst practical men. That fine promenade was originally a grand conception; but for years it has been evident that the Deodars were not succeeding. On the contrary, they have proved a failure; for, from the time they have been planted, they ought to have been twice the size they are at present. It is now proved that, except in the south of England or in certain favoured localities, Deodars are not sufficiently hardy for our climate. But why should not steps have been taken long ago to remedy the error, by planting trees that would have answered the purpose? Surely, from among conifers, plentiful as they have been for years, choice might have been made of trees that would have given satisfaction. It has been long known that the Cedrus atlantica is much harder than the Deodar; therefore, it

might have been planted between the Deodars, the latter being allowed to remain until the atlantica had attained sufficient size to be effective. As an additional provision against failure, outside the Deodars might have been planted a row of such trees as *Picea nobilis* or *grandis*, both excellent for avenues; and between them some other sort, for the purpose of having the choice of which should ultimately remain. Again, a row of *Picea lasiocarpa* or *P. nordmanniana*, or any other suitable species, might have been planted inside the Deodars, where the objectionable deciduous trees now stand—for which, surely, some more suitable locality might have been found. Each group, as has been shown, consists of three different species, from widely different parts of the world; they may, therefore, be expected to grow into all sorts of sizes, habits, and hues, quite unfitting them for an avenue where uniformity is an important feature.

With respect to the Sion Vista, your correspondent's remarks do not apply with so much force. Here, also, the original conception was good, but the Deodars have failed to fulfil their mission; and I am disposed to think Douglas firs and evergreen oaks in opposite threes, alternately, rather a good idea, as a choice between the two is thus afforded, and if they succeed, they are both good avenue trees. As to the examples of *Cupressus Lawsoniana* referred to, they extend from the American garden only, on the west front of the Palm House, to the wire fence, and being in keeping with other surroundings, cannot be considered to be very objectionable.

The new vista opened through the wood from the Pagoda towards the head of the lake opposite Sion House, if well carried out, might prove a fine feature; but unfortunately at present it looks as if it were a mere makeshift, being much too narrow, not nearly enough of the old trees having been removed to give light and air to those planted to form the avenue, or to give any tree or shrub a chance of succeeding. What, might I ask, is to be done with that huge heap of earth at the head of the lake which terminates the view looking westward from the Pagoda? Is it to be carried away piecemeal, after having been raised to its present height at so much labour and expense? Could it not be made the foundation for a rockwork, which is so much required at Kew? If properly managed, it might be made to present both shade and sunshine for plants requiring either, and would afford a grand opportunity of getting placed out to advantage that immense collection of hardy alpine plants which Kew possesses, and which is now starving in pots in pits or in out-of-the-way places where the public has little chance of seeing it. It might also be provided, with miniature lakes for alpine aquatics; and rude rocky walks might traverse it, so as to enable the public to inspect its nooks and corners in order to find the different gems planted there for its enjoyment. Could not such a feature as this be produced equally well at Kew as at Battersea, and be a noble substitute for that miserable abortion in the way of rockwork that is to be found near the Economic House, and at present the only thing representing rockwork in this, in many respects, fine garden?

Hammersmith, W.

A. DICK.

THE ROCKWORK IN HYDE PARK.

FROM what has been stated in your pages, it seems almost impossible to determine who is responsible for the gardening in our parks. It is intolerable, after putting the best men in these places, that they should be overridden on their own grounds by the Chief Commissioner of Works or his subordinates, who may or may not know a Pelargonium from a Pansy. Why not hold each superintendent responsible for the furnishing and keeping of each park under his care, Mr. Gibson being head over all? Such abortions as the rockwork at the end of the Serpentine are a disgrace to the taste of the age, a reckless waste of public money, an outrage on congruity, and an exhibition of the very worst sort of Cockney tea-gardening. It is to be hoped that some member of Parliament will move for a return as to the cost of planning (?), building, and hiding that rockwork? Everyone has a right to insist that this abortion be removed. Supposing the Commander-in-Chief were to order a regiment of soldiers to stand on their heads, would either officers or men obey? Undoubtedly not. But such a whim would not be a whit more absurd than the placing of rare conifers in rustic vases formed of clinker and cement, or the thrusting of a *Reticnospira*, two *Rhododendrons*, an *Ivy*, a *Gonista*, a *Daphne*, and a small *Cedar*, all into a single hole only large enough for a house-leek. Such an exhibition is the more to be regretted, as there are really many fine examples of good gardening and furnishing in the parks. Year by year they are becoming more rich and beautiful, and, if left to their proper superintendents, I have no fear but the future will excel the past. But if this is a sample of our statesmen's style of landscape gardening, for the credit of the nation, I trust we shall see no more of it. A man might arise who could govern an empire, or plant a garden with equal

ease; but such combinations are rare; and our statesmen might surely be better employed than ordering *Pelargoniums*, *Verbenas*, &c., by the thousand, and giving instructions where to plant them.

The same want of knowledge is equally apparent in regard to planting trees. For years past horticulturists have been crying out against the folly of planting evergreens in London. The dust chokes, the soot smothers them, and there is speedily an end of them. Deciduous trees and shrubs, on the contrary, get a new start annually; they drop their smothered leaves and begin life afresh; the bare boughs get washed clean in winter, and thus the plants thrive in spite of smoke-dried air and London dust. But the official mind ignores all this, and plants evergreens. The remedy is obvious. Let practical men be supreme in their own sphere, and let statesmen be content with the privileges of paying for and enjoying results; then such a monstrosity as the Hyde Park rockwork would be impossible. Of course the step from the sublime to the ridiculous is easier by way of an artificial rockery than by almost any other path. And, apart from its glaring faults in construction, the whole attempt in Hyde Park was doomed to failure from the smallness of the area. In such a position, unless bold scenery on a commensurate scale with the surroundings could have been formed, nothing of the kind ought to have been attempted. As well attempt to force the grandeur of mountain scenery into a nutshell, as form a rockery, worthy of admiration, in such a spot, with such materials, and without a spark of taste or genius.

D. T. FISH.

GARDEN DESIGN.

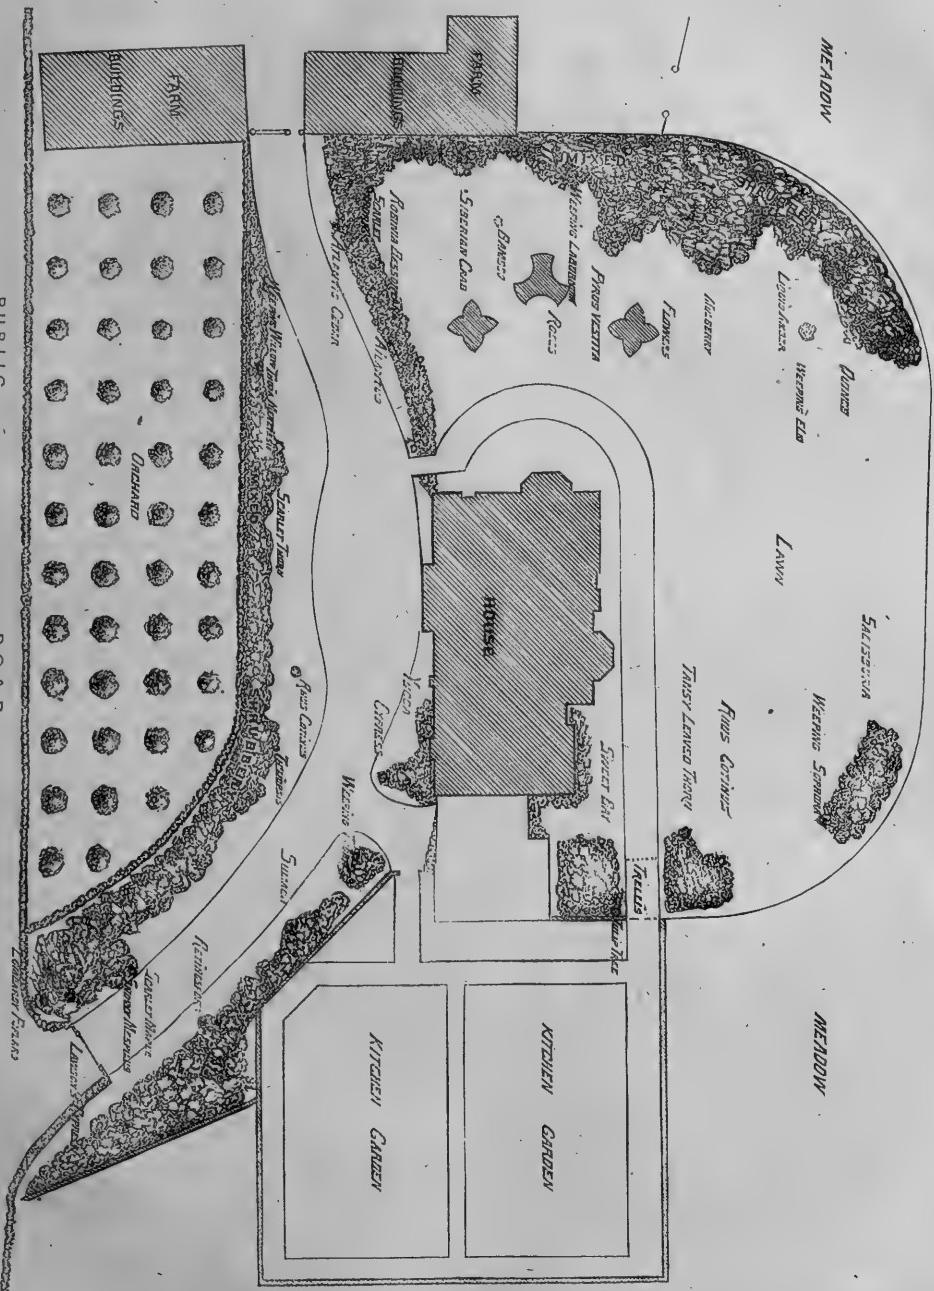

A FARMHOUSE GARDEN.

The annexed plan represents a piece of pleasure-ground and other features belonging to a garden suitable for a farmhouse. The house in question has been recently erected by Mr. W. H. Smith, M.P., near Henley-on-Thames, and is of a handsome and commodious character, far superior to the generality of erections of this kind. Occupied with the many duties of an extensive farm, the owner usually has but little time and labour to bestow on his garden, and, therefore, it has been considered desirable to confine the arrangement to such a scheme as would present little difficulty in the way of maintaining good order with no great amount of labour. Gravel-walks, flower-beds, and the like, have, therefore, been avoided; and for the same reason, the piece of ground that bounds the public road has been allowed to remain as an orchard, in preference to converting it into dressed ground. It will be seen that this strip is screened from the dwelling-house by a belt of shrubbery, as are also the farm buildings and cottages on either side. These shrubbery plots consist of a mixture of ordinary plants, both evergreen and deciduous, with a few light growing trees where necessary, such as *Acacia*, Mountain Ash, Laburnum, and *Gleditschia*, intermixed with them.

With regard to shrubs or trees for special positions, an attempt has been made to plant only such as would render the garden as interesting as possible, by means either of flowers or fine foliage, and thereby, in some measure, compensate for the absence of flowers in borders and beds.

With respect to planting, considerable attention has also been paid to mix in with the ordinary occupants of the place various trees, which, in addition to their ornamental character, might be found useful for domestic purposes, such as the quince, Siberian crab, medlar, &c. The open grass space on the private front of the house might be made available as a croquet ground; it is therefore kept free from both plants and flower-beds. All the finer hardy herbaceous plants might likewise be arranged on and near the margin of the shrubberies, and in that way a good deal of floral beauty would be introduced with good effect and at little cost.

Adulteration.—The principal of the Inland Revenue Laboratory, Mr. G. Phillips, reports that 432 samples of tobacco were examined by him in 1870 for the Excise Department, and 312 were found to be adulterated, the adulterants being wheat and rice starches, sugar, liquorice, lambblack, catechu, and colouring matter. The amount of adulteration ranged up to 4 per cent. starch, 40 per cent. sugar, 55 per cent. of liquorice. Almost all the samples found adulterated with sugar and liquorice were "Cavendish." It is believed that it is smuggled into this country in small quantities by sailors.

THE INDOOR GARDEN.

GLOXINIAS FOR WINTER BLOOMING.

I do not think it is generally known how easily Gloxinias may be had in bloom in winter, and how very beautiful they are, either for decorating a cool stove or for cut flowers. For this purpose I recommend plants raised from seed. No one who has not been in the habit of raising seedlings of those plants can form any idea how much more vigorous they are than those raised from cuttings; and for merely decorative purposes, they are far superior. Of course, I admit, if it is desired to perpetuate any particular variety, it is absolutely necessary to do so by means of cuttings. Several years ago I saved seeds from a flower of great substance, and of a peculiarly rich dark crimson colour, that had not, so far as I was aware, been crossed with any other variety; but the seedlings produced flowers of all shades of colour, between crimson, purple, and white, but not one like the parent; in this respect they are very variable. The plants we have now in flower were raised from seed about three years ago, and the largest are in nine-inch pots; some of the bulbs are upwards of six inches in diameter, and if we could have spared room to have given them a shift into twelve-inch pots, the plants might easily by this time have been three feet in diameter. Of course, I do not say the flowers are equal to those of the best named varieties for exhibition purposes, but many of them are large and very pretty; I am, however, only speaking of them as decorative plants for winter. I like the erect flowered kinds best; for they are more useful for cutting.

The seeds should be sown in February or March, in well-drained pots, in peat and sand; fill the pots to within half an inch of the top; press down firmly, and make the surface quite smooth with the bottom of a small pot, giving at the same time a good watering. Sow the seeds thinly and evenly over the surface, and scatter over it a little silver sand. To check evaporation, and thus obviate too much watering, place on the top of the pots a little clean moss. The seeds are so small that heavy waterings would be likely to carry them down so deep as to prevent their growing; but by giving the pots a good watering before sowing the seeds, and a thin covering of moss, and afterwards very little water will be required till the seeds germinate; as soon, however, as the seedlings are up, the moss must be removed, and, when they are large enough to handle, prick them off into small pots, and grow them on in the stove, or a warm pit shaded from bright sunshine, shifting them into larger pots when necessary.

They will begin flowering about July or August; but if the object is to grow them for winter flowering, pinch off all blooms till October, when a few flowers may be obtained the first winter. About March gradually withhold water, and allow them to go to rest. When at rest Gloxinias are treated by many cultivators the same as Caladiums, that is they keep them dry in the stove; but in my practice in treating them as winter blooming plants, and of course at rest the principal part of the summer, early in June they are moved out of doors, and laid on their sides in some partially shaded corner. And I find this cool treatment seems to agree with them, for the rest is more perfect, and when housed about the end of September, they have started into growth, and are ready for potting. The second season, if well managed, many of the plants will measure from one to two feet in diameter. In potting them after the first year, use a richer compost. We always use for large bulbs about a sixth part of thoroughly decayed manure with the peat, and a liberal proportion of sand, and small lumps of charcoal to keep the soil open. When in full growth, supply them freely with water, and maintain a moist atmosphere, and when in flower, water them twice a week with weak clear liquid manure.

There is no difficulty in entirely changing their period of flowering, by resting them in summer, and so having them in flower from November till March, and that too without any special forcing, but by simply reversing their period of rest; but, as I previously stated, I find seedlings much more manageable in this respect than plants raised from cuttings, and there is a strength and vigour of constitution about them that nothing seems to injure. Thrips will attack them, and, if not

stopped at once, will destroy them; the best preventive is a moist atmosphere, without absolutely dashing much water over the foliage, with mild tobacco fumigations occasionally, whether insects are visible or not.

Anyone who has a few named varieties should select three or four of the most distinct, and cross them, save the seed, and give the seedlings a trial against the older kinds. Seeds of Gloxinias may also be purchased from most of our principal seedsmen.

Herewith I enclose a few blooms merely to show how useful they are for cut flowers; but of course they give no idea about freedom of flowering, or size of plants, in which resides their chief value.

E. HORSTAD, *Ramsey Abbey.*

[The blooms in question reached us in the most perfect condition, and were the admiration of all who saw them. The colours were of the most delicate description—clear white, beautifully edged with lavender and crimson.]

STOVE ALPINES.

WHY not have stove as well as hardy alpines? If a more natural arrangement than has hitherto been practised is to be carried out in our glasshouses, of course we shall want now and a bit of rock-work, and in the following list of dwarf plants, many will be found useful for that kind of ornamentation, as well as for other positions of a similar character, in a tastefully planted stove. Where plants of larger size are desired, they may readily be found among Caladiums, Achimenes, and Marantas.

<i>Aeschynanthus fulgens</i>	<i>Dichorisandra undata</i>	<i>Jerdonia laeta</i>
<i>A. Paxtonii</i>	<i>D. minima</i>	<i>Mesolejeunea primuliflora</i>

J. CROUCHER.

VIOLETS.

THANKS to a mild winter, Violets are in bloom a month earlier this season than usual, and thousands of our labouring poor have been for several weeks past, and still are, busily engaged in the gathering and selling of this early spring flower. All round London Violets are grown by acres, and in such a way as would astonish our country friends, who, beyond the culture of a few double kinds in a frame or two, seldom bestow much attention on the cultivation of this delightfully sweet-scented flower, with which just now London markets are almost flooded; the sort being an improved form of the single Russian Violet. They are commonly planted in rows, about three feet apart; the plants being about eighteen inches from each other in the rows. This allows of the hoe to be freely worked, of a plentiful application of manure, and of the growth of crops between the lines during the summer. New plantations are made upon ground on which vegetable crops have been growing, and consist of the strongest and best rooted side shoots taken from the old stools immediately the blooming season is over. With due attention these make strong plants, and yield a considerable quantity of the finest flowers the next spring, and the second year bear a first-rate crop of bloom. Some let them stand another year, but the flowers, although most abundant, are not so fine as from younger plants. The stools will also, by this time, have covered the major portion of the ground. If anyone has some out-of-the-way path that wants an edging, by all means let him get some of these Violets and plant them out along the sides; they will make both an excellent edging and furnish abundance of beautiful flowers.

A. D.

THE FRUIT GARDEN.

APPLE ORCHARDS—PRUNING AND TRAINING.

It is gratifying to witness the great improvement seen throughout the country in the training and management of apple orchards. Formerly, it was the general practice to allow them to grow without care; now, well shaped and well cultivated trees may be seen in every neighbourhood, on the grounds of good cultivators. But still there are many who begin at the wrong end in pruning their orchards, by waiting till their deformities become developed in large or bearing trees, and then lopping off large limbs to remedy the bad shape. This practice not only makes large wounds, which are long in healing over, but it is a sacrifice of what would otherwise be a valuable growth of wood. It is far better in every way to give the young tree the right shape in the first place, and then by proper attention it may be kept so by the easy process of simply rubbing off any wrong or supernumerary shoots as they appear, or, at most, cutting them out with a knife, without the necessity of resorting to the use of the axe or saw.

Fig. 1.

Fig. 2.

Fig. 3.

We give a few illustrations of the proper mode for keeping the tree in the right shape through the successive stages of growth, until it becomes the large handsome shaped bearer—contrasted with deformed shapes not unfrequently seen on the grounds of slovenly cultivators.

Fig. 1 represents a well shaped tree from the hands of the skilful nurseryman. The head consists of four or five branches, which are to form the framework of the future tree—the only subsequent care

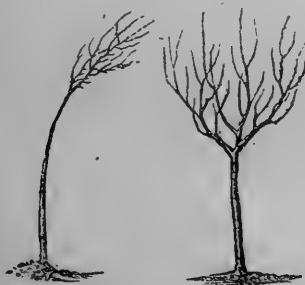

Fig. 4.

Fig. 5.

being the preservation of just enough side shoots along these branches as they increase in growth, to form a thrifty, evenly distributed head—these shoots in their turn to supply others, as they become larger. Purchasers of trees, however, who desire to get their trees at as low a price as may be, are unwilling to pay for those which are thus handsomely worked, and receive such as are shown in fig. 2, which have grown three or four years with very little attention.

These will need special care to give them a right shape as soon as practicable, the best treatment for which is to cut the top off at the dotted line, which will give a form like fig. 3, and from which a good shaped head may be made.

Sometimes unskillful nurserymen trim up their young trees so closely, in order to supply the call for "tall trees" from equally unskillful planters, that the slender stem is unable to sustain the mass of leaves and shoots at the top, and they assume the form shown in fig. 4, reminding one of the "bowing bean." Avoid buying such trees—or, if once on your hands, they may be cut back as already described, and possibly a head may be obtained from the new shoots.

It should be borne in mind that all cutting back and pruning for this purpose must be done very early in the season and before the buds begin to swell; for if done later, it will only check instead of helping growth.

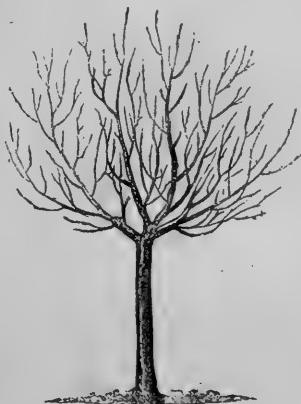

Fig. 4.

By keeping an occasional eye on the young orchard, and rubbing or cutting out any needless shoots which may spring up, the trees in a few years will present the appearance shown by fig. 5; and by continuing this care as they grow larger, they will appear like fig. 6, which shows the bare branches without leaves.

A well managed tree, as it begins to come into full bearing, is shown by fig. 7; and when of larger size, by fig. 8. If the lower branches of such large trees become too drooping by the successive loads of fruit giving them too low a position for easy cultivation, a few may be readily removed with the saw. Where nothing very particular is grown under them the branches may be allowed to

Fig. 7.

remain near the ground for the convenience of picking, and treated thus they will also furnish a larger bearing head.

Having now given suggestions for keeping the trees of an orchard in proper shape (which to be successful must always be accompanied with good, clean cultivation, except on the very richest soils), we add additional illustrations of badly cut and mutilated trees by way of contrast, and for the purpose of inducing young planters to avoid

such management. The mode of pruning old trees shown in figs. 9 and 10 may still be occasionally seen, but we are glad to state that it is rapidly giving way to a better treatment. Workmen who know nothing about trimming trees, are sent into old orchards with axes,

Fig. 8.

by owners who know no more, and soon reduce good old trees to such distorted forms as these figures represent—the first being what may be termed a "sprawler," and the second a "two-story" tree with a scanty attic.

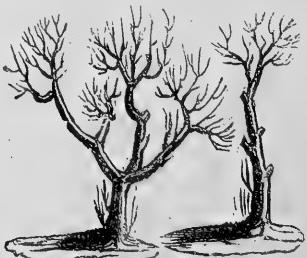

Fig. 9.

Fig. 10.

When apple trees become old, new vigour is sometimes imparted to them by a moderate pruning of the tops at a season when destitute of leaves, and before the buds swell. This pruning should be gradual, or performed in two or three successive years, beginning at

Fig. 11.

the top and working downwards, leaving the main branches; and not as figs. 9 and 10 represent, by beginning at the bottom and running upwards. But as a general rule, we do not advise any attempt to restore quite old trees in this way. When the trees have reached old age, they ought to be replaced by new ones. It is rare that apple

trees live much over sixty years in the best fruit regions of the eastern and middle States, and rarely over forty years at the west, and when they have thus fulfilled their destiny, they may be discharged, and new ones brought on. But trees which are not over twenty or thirty years old may be often much improved, especially if in connection with regrafting to better sorts. In this case work downwards, taking two or three years for the operation, as already described, giving them, not the form of fig. 10, but of fig. 11, which shows the young shoots, from grafts or otherwise, springing up and forming a now, handsome, symmetrical head.—*Albany Cultivator.*

GRAPE ROOM AT ASWARBY PARK.

Our grape-room—that is, the apartment in which we keep our bottled grapes—is on the second floor in a north aspect, and therefore dry and free from sunlight. The three great evils to guard against are damp, frost, and artificial heat. Our room is twenty-one feet by sixteen feet, and seven feet six inches in height. The walls are thoroughly plastered, the ceiling having three coats; and above the ceiling and between each rafter is packed clean dry sawdust, to act as a preventive against frost. The north and east walls of the room are exposed to the open air; the west and south are inside walls, which assist in keeping out frost. The floor, which consists of composition, is always covered with clean dry sawdust. There is no ventilation from the roof, but two windows look towards the north, and are fitted with shutters inside to be closed in severe weather. The space between the shutters and windows is padded with clean, dry material in frosty weather. The door, which is on the south side, can be converted into a double door when required; the space between being like the windows, closely padded, so as to make the room in frosty weather almost air-tight. Ventilation is wholly derived from the door, and windows, which open and shut as required, as thorough ventilation with a good amount of light is required at all times whenever the weather will permit. When the day is damp and cloudy, or the wind in the north, the room is not opened; still, I never lose a chance of admitting light and air, if only for half-an-hour. On the 8th of December, when we had 20° of frost, the temperature in the room did not get lower than 38° without artificial heat. The temperature is kept as near 48° as possible, and with careful attention the room will stand for weeks at that temperature. At each end are arranged fruit shelves for the best varieties of dessert pears and apples; the centre being devoted to the grapes. We have eight standards, 6½ feet high and two inches square, with brackets let into two sides of them alternately; the brackets are 1½ inch thick, and after being let into the standards are 4½ inches by 3½ inches. Four of these standards are placed on each side of the room, leaving a passage-way all round them. The bottle receptacles are then laid on the brackets, on which they rest perfectly flat. They are then made fast with a screw, which passes through from the underside of the bracket and enters the underside of the receptacle. A light facing of wood is fitted to the face of the standards from the underside of the bracket, and rests on the top of the bottle receptacle. This prevents the receptacle from rising up behind, and gives the whole a neat and finished appearance. Each pair of standards carries seven ten-feet lengths of bottle receptacles, four on one side and three on the other. Each length holds eleven bottles, so that each pair of standards carries seventy-seven bottles. Each standard has an iron spike in its top, which, passing through laths of wood fixed there, binds all firmly together.

After trying experiments in many different ways, I find nothing to equal charcoal and pure rain water for grape preserving. The shoot with the bunch of grapes on it is placed in the bottle close to the water, but not in it. When the grapes were nearly ripe, I thought to myself, I must not cut all, if I can, at once—for this reason, that every bunch of grapes in the house does not ripen at the same time, nor yet in the same week. Ten or twelve days before cutting any to take to the room, I went over all the bunches in the Muscat house, and selected from forty to fifty that had arrived at maturity; I shortened back the shoots to two eyes above the bunch, and the small laterals attached to those two eyes were allowed to remain. I am now speaking of Muscats alone, the foliage at the time being quite healthy and green. My vines are trained on the extension system, and forcing was commenced on the 7th of March. Cutting back the shoots ten or twelve days previous to cutting off the bunches to take to the room obviates the use of sealing wax or any other material in that way, as the wound becomes perfectly hard and dry of its own accord, and will neither take up nor give off moisture. The day before cutting I have the charcoal and water put into the bottles. I then have all the selected bunches cut and taken to the room, cutting the shoots off at two eyes below the bunch when possible to do so, with all the green foliage attached, allowing it to

die off of its own accord, which takes from three to four weeks. After the grapes are in the room the leaves must be carefully gathered up as they drop, and at once removed. Having disposed of the first lot of grapes, I go to the viney again, and select another quantity to come in succession. This to some may seem a slow process, but I am satisfied that it is a better plan than leaving the grapes on the vines.

The foliage was nearly all off Lady Downe's Seedling when I cut my bunches of that sort. This autumn I shall select them the same as I did the Muscats. I may add that the bottles are all stopped with wadding. The time, I apprehend, is not far distant when grape rooms will be as common as fruit rooms, and they will answer the end in view quite as well, provided they receive proper attention. People must not think that grapes will keep in a room for four or five months without careful looking after.

RICHARD NISBET.

Aswarby Park, Farningham.

FORCING STRAWBERRIES.

It is an old and familiar truism that "there is nothing new under the sun"; still, as time progresses fresh readers spring up, for whose advantage it is sometimes desirable to discuss questions that some of us look upon as definitively settled: Forcing strawberries is in many places an important part of a gardener's duties; and to keep up a constant succession from March—which is as early as they are required in most establishments—till they can be gathered in the open ground, requires a good deal of forethought and attention. After trying a good many varieties, I think the following may be relied upon—Keens' Seedling, President, Sir Charles Napier, and British Queen. If very early fruit is required in January or February, Black Prince forces well, and may be grown to a fair size by severe thinning. Bicton White Pine I have found very useful when several dishes are wanted—at the same time, as it gives more variety. Trollope's Victoria is a heavy cropper and sure bearer, and a large showy fruit, but not first-rate in flavour.

In preparing the plants the best way is to lay the earliest lot into small pots, and it is important that this should be done as early as possible in the season; for later crops I have often laid them into the fruiting pots at once to save time, and always found them do well. I would strongly recommend the following plan to anyone who has a difficulty in procuring early runners in sufficient quantities. I need not say how important it is that plants for early forcing should have plenty of time to develop and mature their growth. In September take a sufficient number of the late runners and plant them six inches apart in a prepared bed in a frame, give them a good soaking of water, and after they are established take off the lights and only cover them in severe weather; pinch off all flowers that show in the spring, and about the third week in May pot them in the fruiting pots. I have never known plants so treated fail. They have plenty of time to fill their pots with roots; and to plump up their crowns; give them a few doses of weak liquid manure, but don't over do it, or late growths may be excited when the aim should be rest by a moderately dry treatment. Shelter of some kind from heavy rains and cutting winds is necessary from October till forcing begins about Christmas. In selecting the runners, care should be taken to obtain them only from the most prolific or fruitful plants, as the absence of this care is often the cause of strong healthy-looking plants turning out blind or unfruitful. Thirty-two sized pots are the most suitable for the fruiting size; but good crops may be grown in forty-eights by plunging the pots in troughs or boxes half filled with rich soil, or by plunging them into other pots two sizes larger in the same way. Don't be deterred from adopting this plan by any exaggerated ideas about the labour, for it is a mere trifle, and time will be saved in watering, and I am sure the result will be satisfactory. The best soil for strawberries is a good sound loam, adhesive rather than sandy, moderately enriched. The best way to prepare it is, when the sods are cut to pack them in long square heaps in alternate layers of sods and manure, putting in of course only the proper proportion of manure, which must depend upon the quality of the loam. In about eight months it will be ready for use.

I have known gardens where there was great difficulty in procuring loam of good quality, from the natural soil of the

district being of a light sandy nature, without sufficient body or strength to suit strawberries well in pots; and, although by adding manure it could be made rich in organic matter, still that did not supply the necessary weight or firmness; if I may so term it. I believe in most light land districts beds of marl or clay are commonly found, the value of which is pretty well known to light land cultivators. It may generally be had on most estates for the carting, and nothing rectifies a light soil like clay. In such cases it is always desirable to keep a few loads in the compost yard and a few bushels dry in a shed ready for use for strawberries, melons, or any other crop that does best in a strong soil. When required for use, break it up as fine as sand, which, as it is dry, there will be no difficulty about doing; take out all stones; and in this state it will mix thoroughly with any soil, so as to be in a condition for plant food. I have generally found about one-sixth of clay the right proportion; but no hard and fast line can be laid down. I am convinced, if anyone who has hitherto had a difficulty in growing good crops of strawberries from the sandy nature of the loam will try this plan, he will find his difficulties disappear. In potting, ram the soil in firmly, keeping the crowns well up.

In commencing forcing, if a pit can be spared, fill it with leaves to within six inches of the glass, treading it down as the work proceeds. Plunge the pots about half their depth, and introduce a fresh batch in succession every fortnight. Give a little air night and day except in severe weather. Don't water too freely till the flowers appear, in order to induce the flowers to come away well with the foliage. At this stage, if desirable, they might be moved to a light house to make room, where the night temperature does not exceed 60°, and where air can be given freely till the fruit is set. Thin the fruit to about ten or twelve on each pot, removing all late blossoms. Push the plants on rapidly with a higher temperature and plenty of moisture, using the syringe freely amongst them twice a day; if not looked after well in this respect, red spider may attack the foliage and spoil the flavour of the fruit. Although I recommend the mild genial warmth of a pit filled with leaves for starting strawberries in January and February, still good fruit may be obtained without its aid by utilizing the back shelves of peach houses and vineries in the usual way; and the gradual advance in temperature in such houses will suit them. After the fruit is set the plants may be moved to the pine stove or any other warm house or pit if wanted early. Place a saucer under each pot, but don't allow the water to remain in it to become stagnant, or the roots may become unhealthy. In forcing strawberries, and, indeed, this remark is applicable to all other kinds of forced fruit, the great secret of success lies in the previous year's preparation. If the plants have been well selected, well grown, and well matured, there will be no difficulty under reasonable treatment in fruiting them. With successive crops, as the days lengthen and there is less risk of their setting, thin the blossoms without waiting for the fruit to set, as it is only a waste of force to leave all on till that is accomplished. Place a small stick to each cluster of fruit, tying it neatly up; it brings the fruit nearer the sun, and keeps it clean from the manure water; and I have an idea that the fruit swells more rapidly when kept in a vertical position, from the admitted tendency of the sap to flow upwards in a direct line. In using liquid manure, there is nothing much better than that made from sheep droppings with a little soot added. I prefer to use it weak at every watering from the time the fruit is set till it begins to colour, rather than give strong doses at intervals. In preparing the stock of plants, provide liberally, so as to have a hundred or so to come on in a cold pit without forcing, as there is often a break in the supply in many places between the forced fruit and those in the open ground, which such an arrangement will prevent.

E. Hobday, Ramsey Abbey, in "Field."

THE AMERICAN BLACKBERRY.

The Rochelle or Lawton blackberry has been despitefully spoken of by many; first, because the market fruit is generally bad, being plucked before it is fully ripened; and next, because in rich clayey grounds, the briars, unless severely cut back, and again back, grow into a tangled, unapproachable forest, with all their juices exhausted in wood. But upon a soil moderately rich, a little gravelly

and warm, protected from wind, served with occasional top-dressings and good hooings, the Lawton briar bears magnificent burdens. Even then, if you would enjoy the richness of the fruit, you must not be hasty to pluck it. When the children say with a shout, "The blackberries are ripe!" I know they are black only, and I can wait. When the children report, "The birds are eating the berries," I know I can still wait. But when they say "The bees are on the berries," I know they are at full ripeness. Then, with baskets we sally out; I taking the middle rank, and the children the outer spray of boughs. Even now we gather those only which drop at the touch; these, in a brimming saucer, with golden Alderney cream, and a spoonful of powdered sugar, are Olympian nectar; they melt before the tongue can measure their full roundness, and seem to be mere bloated bubbles of forest honey.—*My Farm of Edgewood.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Grapes in Bottles.—THERE are few subjects upon which all agree. Therefore I am not surprised at Mr. Tillery supporting the bottling system. Muscats, I am aware, suffer less by it than any other kind, on account of their being naturally higher flavoured. I am personally acquainted with no fewer than a score of gardeners who adopted the system because of the convenience it afforded, but who have been compelled to abandon it, because their employers complained that grapes so treated were deficient in flavour. I can assure Mr. Tillery that long before I grew specimen plants I grew grapes; and that I found it easier to produce them up to the required standard than plants. I am ready to admit that the practice of preserving grapes in bottles is admissible under certain circumstances. Twelve months ago, I bottled about half a hundred weight, the produce of vines I found here two years ago in a condition impossible to produce first-class fruit. My object in bottling them was to relieve the vines. When I get them into the condition which I hope to be able some day to have them, no bottling for me.—T. BAINES.

—WE have recently received from Mr. Wm. Tillery, of Welbeck, examples of Muscat grapes, preserved in bottles for three months, which, for flavour and general condition, were all that could be desired. They have begun to shrivel since being taken out of the bottles; but even the most shrivelled and uninviting-looking of the berries still retain their good flavour.

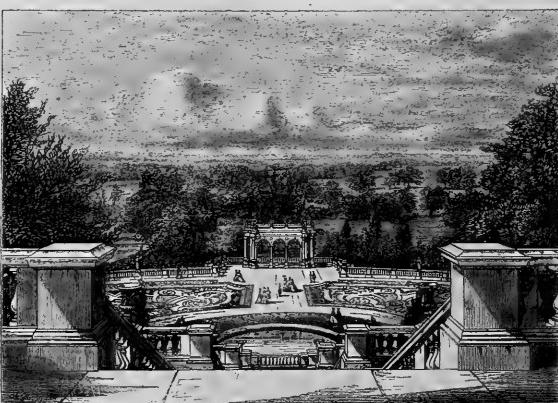

Profits from Strawberries.—Our friend, William Parry of Cinnaminson, N.J., gives some details about strawberry culture. He says: "In the spring of 1870, before planting strawberries, we opened furrows three feet apart, and spread along them a mixture of fine ground bones, unleached ashes and marl, then turned a ridge on it and set out the plants. They made a vigorous growth, and in the summer of 1871 produced the finest crop of fruit we ever grew. Six acres, mostly of Boyden's No. 30, Charles Downing, Wilson's Albany, and Kentucky, yielded 46,000 quarts, and sold at an average of 16.7 cents per quart in market, amounting to 7,682 dollars, or an average of 1,280 dollars per acre. The Boydens were the best strawberries we grew. One whole shipment sent to New York brought 38 cents per quart, being the highest price obtained during the season."—*American Paper.*

Scale on Currant Trees.—Are the scales on the enclosed currant sprays the eggs of insects? and, if so, what kind? and how can I exterminate them? They are too numerous to cut off. Would a dab of Baltic tar, or of that cast-grease, be likely to imprison them, and so cause their death?—R. V., *Seaford Grange, Pershore.*—[What you have sent us is *Coccus peltiformis*. We should recommend washing with *Gishurst Compound*, and brushing the scales off with a nailbrush where practicable. It is probably too late now; but in mild weather in winter, when the buds are quite dormant, hot water, varying from 150° to 160° is reported to kill scale.—A. M.]

THE GARDENS OF ENGLAND.

SHRUBLAND.

LIKE most fine gardens, those of Shrubland owe much to their site; they occupy more than half a hundred acres of beautifully hanging ground, on the side of a well-wooded deer park. The mansion, a fine specimen of the Italian style, remodelled, extended, and improved by Sir Charles Barry, crowns the gardens, and has impressed much of its character upon a considerable portion of them. The position of the house is most commanding, and it forms the chief feature in the landscape for many miles round. It overlooks not only the grounds, but the Valley of the Gipping, that winds out and in among the green fields like a silver thread, till it expands into the deeper, broader Orwell at Ipswich. Standing in front of the mansion, overlooking the grand flight of steps seen in the accompanying representation, the whole of the middle distance and foreground is a series of gardens, following each other in different styles, until the eye seeks rest on a belt of wood that fringes the garden boundary in the far distance. Near to this a large artificial lake has recently been formed, and between the steps and this like, broad glades of sweeping turf and huge masses of shrubs bring the eye forward to a natural-looking labyrinth, planted with all sorts of semi-wild and common plants. Rough irregular mounds of earth have been thrown up, and furnished after the manner of undressed nature. This style is carried right up to the retaining wall that bounds the panel garden. The annexed illustration furnishes a good view of this part of the gardens, as seen from the grand steps. Immediately beyond the panel garden is nature wild and free, then lawn dressed with shrubs—lower down fringed again with flowers, merging finally into wood

Shrubland: View from the House.

or water. The sudden transitions from the wildness of nature to the trimmest formalities of art are not uncommon throughout these gardens. Such violent contrasts are fairly open to criticism; but where a picture, as at Shrubland, has to be spread over a surface sixty acres wide or long, strong lights are needed to prevent the scenery becoming monotonous.

The great garden terrace stairs, so prominent a feature in our illustration, consist of about a hundred steps, twelve feet wide, with four rests over twenty feet wide, and a central landing, from which they swerve to the right and left within about a dozen steps of the bottom. Their whole flight connects the panel garden with the balcony garden, immediately in front of the mansion. A broad belt of evergreen shrubs, mostly box, hug and hide each side of the staircase to the base of the balustrading. At each projecting rest these shrubs are carried up higher, and thus the even line of green, that might otherwise be objectionable, is broken. The vases with which the balustrading is ornamented break it in another manner, by means of masses of scarlet pelargoniums, with which they are crowned. Pyramidal trees also run up among the shrubs, which merge into the adjoining wood. At the bottom of the steps, and almost close to them, two beds of yew, with a mixture of variegated box, so disposed among it as to represent a light-coloured serpent lying lazily on a green cushion, have a unique

as well as a singular effect. There are also several beds or masses of *Juniperus sabina*, which likewise, in some measure, tend to subdue the white appearance of so much stone. And a beautiful hanging wood cuts the house, balcony gardens, and lawn off from the series of other gardens lying a hundred or more feet lower down.

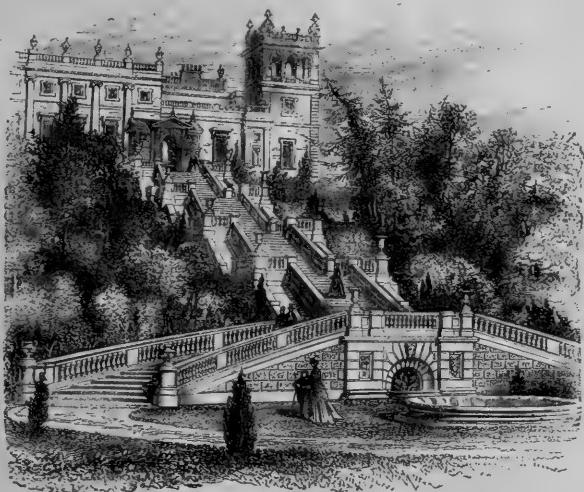

At the bottom of the grand steps, a noble grassy glade stretches so far to the right and left in straight lines as to lose itself almost in the distance. This glade is, one of the finest features of Shrubland. It skirts the base of the hanging wood on the one side, and a whole series of gardens in different styles of form and planting rest upon it on the other. Proceeding to the right from the panel garden, one gets glimpses of the fountain garden, burnished with colour; and half enclosed, as it were, with a conservatory wall, further on, are the quaint Chinese garden, the box embroidery, verbena garden, and maze. Below these again, the poplar, rose, and tent gardens are situated; and from these, detached groups of flowers and shrubs stretch away towards the outer fringe of wood and the lake. On the opposite side of the glade a huge ribbon border, consisting mostly of Dahlias, occupies a niche out of the wood; and further on, near the gate leading to the park, the Swiss cottage, with its garden and rocky fernery, is placed. From this point, and from what may be termed the looking-glass garden, two brilliant borders lead up to an open summer-house with a glorious picture—the subject a charming landscape in front. Coming closer, this is found to be a far-reaching view of the surrounding scenery, all the more enjoyable because of the illusion. From here, the upper lawn is immediately reached, which rises up to the noble conservatory attached to the drawing-room, and sweeps onwards to the balcony garden at the top of the steps, and far beyond it. The lawn, which slopes beautifully from the house, skirts the base of the mansion on one side, and top of the hanging wood already adverted to on the other.

Shrubland, like most buildings in the Italian style, has a series of terraces, with retaining walls of great massiveness and beauty, and on these terraces garden art is made to fraternise with that of the architect. Tiny beds, bordered with the whitest of silver sand, are furnished with flowers of various sorts, in thin lines and little grouplets. By-and-by these fringes become wider, and the grouplets broaden into masses, till hollyhocks lift their towering stems proudly above heavy stone walls, and are supported with rich masses of glowing pelargoniums. As regards the intermediate space between the mansion and the grand steps, some large beds, placed on each side of the centre walk, are filled with several hundreds each of pelargoniums, chiefly in broad bands, the varieties used being such as pink cerise unique and Golden Cerise, finished with the old brilliant Baron Engel as an edging. Then, on each side of the walk are set fine standard Portugal Laurels. Further, masses of *Humea elegans*, Spiral Juniper, and similar plants, together with stone baskets and vases,

link together the house and the steps and form the balcony garden.

Proceeding to the left of the balcony garden, a wide walk sweeps the extremity of the pleasure-grounds and lawn, and passes under, or near, nine of the finest Sweet Chestnut trees in the kingdom. They are supposed to have endured the changing seasons of probably a thousand years, are marked with the scars of many a storm and whitened with the proofs of hoary antiquity. This walk terminates in a seat, from whence a fine dell in the deer park is seen, mostly furnished with Sweet Chestnuts of almost equal size and age. Passing down the end of the grounds, here a lower level is reached, and a straight path leads along between a raised bank on the right, furnished with blocks of wood, &c., covered with a rank growth of wild, rampant vegetation. On the other side a modern ribbon border is placed—nature and art once more in violent contest, rather than contrast. And here nature has the best as well as the most of it. A few steps more, and we are in the panel garden again, at the bottom of the steps, with its splashing fountains and all the glory of its floral and architectural accompaniments.

Of late years, perhaps, art has dominated somewhat too strongly over nature at Shrubland. This is almost the inevitable result where great architects become also landscape gardeners. They naturally carry their building tastes with them. Still, both architectural and natural beauty have been on the whole well blended at this fine place. Shrubland is one of those uncommon places where the nature of the ground near the house really demands a terraced garden. Our illustrations have been lent by Mr. Murray, from "The Life and Works of Sir C. Barry." D. T. Fish.

Shrubland from the Gardens.

The leaves may well scorn the comparison. We, who live for ourselves, and neither know how to use nor keep the work of past time, may humbly learn—as from the ant, foresight—from the leaf, reverence. The power of every great people, as of every living tree, depends on its not effacing, but confirming and concluding, the labours of its ancestors. Looking back to the history of nations, we may date the beginning of their decline from the moment when they ceased to be reverent in heart, and accumulative in hand and brain; from the moment when the redundant fruit of age hid in them the hollowness of heart, whence the simplicities of custom and sinews of tradition had withered away. This lesson we have to take from the leaf's life. One more we may receive from its death. If ever in autumn, a penitiveness falls upon us as the leaves drift by in their fading, may we not wisely look up in hope to their mighty monuments? Behold how fair, how prolonged, in arch and aisle, the avenues of the valleys; the fringes of the hill! So stately—so eternal; the joy of man, the comfort of all living creatures, the glory of the earth—they are but the monuments of those poor leaves that fit faintly past us to die. Let them not pass, without our understanding their last counsel and example; that we also, careless of monument by the grave, may build it in the world—monument by which men may be taught to remember, not where we died, but where we lived.—John Ruskin.

THE LESSON OF THE LEAF.

We men sometimes, in what we presume to be humility, compare ourselves with leaves; but we have as yet no right to do so.

THE SIX OF SPADES.

CHAPTER VI.

And thus those gentle ladies survey with an amused benevolence the anxious difficulties of their faithful Joseph. Who, indeed, could be seriously angry with him, beaming, as he does, from a desire to please, and glowing with a determination to do his best? If on your coat some venial gravies fall, look in his face, and you'll forget them all. He impinges, I confess, upon his fellow-servants, at times when their equilibrium ought to be especially respected, as, for instance, when they are engaged in the administration of coffee, in the setting on of lamps, and the like; but only from an earnest, affectionate wish to hand you your muffin hot, an anxiety to get at you with something to eat—a noble sympathy, which, to feed you, my friend kicks the shins, treads upon the corns, and ignores the proximity of meaner men. You do not approve, and I do not justify, the deep immersion of his thumb in the Trifle, as he places it proudly before you, although his Berlin glove is of snowy whiteness. ("I would I were a glove upon that hand," whispers your comic neighbour, "that I might kiss those sweets!"); but we must both of us admire his attentive care of that beautiful crystal bowl, which he insists on carrying, to the intense terror of the whole household, knowing, as we do, that rather than break it, Joseph Grundy would prefer to be "set quick i' the earth, and bowled to death with turnips."

Only once, within my cognizance, has he been seriously, nay sternly, censured; and this on the occasion of an appeal which he addressed to Miss Susan, for the loan of a certain single-barrelled gun, "to shoot them audacious blackbirds." He affirmed that they not only stole his fruit, but that, when he drove them away, they just "popped on to the top of the wall and then turned round and *sauced* him." He had invented scarecrows of such repulsive aspect as would have scared, he was sure, any decent birds into fits; but those brutes had come back, as imperious as imperious. One effigy, that of a gentleman fully armed with the artillery which Joseph desired to realize, and threatening grim destruction to all around, they had treated with conspicuous scorn, sitting upon the fowling-piece, "disgusting," as Mr. Grundy said, and using the entire creation as a kind of lounge, and worse. So had they exceeded in effrontery those their naughty brothers of whom we read in a recent delightful biography,* that when the ladies set up an old packing case, with a piece of red bunting affixed thereto, as an object which could not fail to dismay the winged banditti of the neighbourhood, "they stood upon the box, to eat the cherries, and then wiped their beaks on the rag!"

Were not these provocations sufficient, think you, to disturb even the placid spirit of a Grundy, and to make sour within him the rich custards of his human kindness? A mouse, we read, set the lion free; and a blackbird may rouse the British ditto, even as the twopenny tin horn of the bird-tenter may excite the startled hunter, or speak to the charger of war. So there he stood, erect in all the majesty of wrath, bold as Ajax defying the lightning, and suggesting that he should like a gun.

And wherefore is Miss Susan mute? Stands she aghast, astonished, speechless, at the indelicate behaviour of the feathered tribe, or wherefore is she dumb? She loved those blackbirds well, and now she wears the strangely piteous look of one hearing, for the first time, harsh things of her beloved, and listening to the most respectable evidence that the joy of her soul is a thief. There she stands, grandly indignant, like the Lady Ida, when she found three men in petticoats among her "sweet girl-graduates":—

"A tide of fierce
 Invective seem'd to wait behind her lips,
As waits a river, level with the dam,
 Ready to burst, and flood the world with foam."

But Miss Susan keeps the flood-gates closed, and without a word, the heart's stream too flush and deep to ripple, she walks slowly, sternly, to the house.

But it is not the birds, my reader, who have caused this sad dismay. It is "animal implume"—it is Joseph Grundy, for

whom this stillness in the air portends a thunder-storm. Two hours afterward it fell.

I must tell you, first of all, that a real shower, material not metaphorical, had just refreshed the earth, and all the leaves of the glossy evergreens were shining, "as if" (Mrs. Verjuice beautifully said) "every one of 'em had been French-polished," when Miss Susan went forth to speak her mind. Poor Joseph's mocking bird was singing on the tree, as though he had wet his whistle to some purpose, and had clarified and strengthened his throat with raindrops, as the operatic songstress with stout.

"Then Ida, with a voice that like a bell,
 Tolled by an earthquake, in a tumbling tower,
 Rang ruin, answered, full of grief and scorn."

"Grundy," she said (he told me subsequently, with intense pathos, that she had not addressed him by his surname since he upset "them gold fishes," fifteen years ago, and he would much have preferred that she had commenced with "Pick-pocket"); "Grundy, be good enough to listen to that flute, and tell me which particular tones are inferior in sweetness to your big bassoon. And tell me at the same time, Mr. Joseph" (he would repeat the "Mr." with an extreme disgust, as though it were an epithet too vile and dreadful for any but the confirmed garrotters), "tell me why that chorister in his black cassock should not sing his anthems all the year round, as you once a week in the choir. It may be my want of taste, Joseph Grundy, but I prefer the tune which he is now singing, to your favourite, 'Bobbing Round! Shoot the Blackbirds! Kill our Minnesingers!' I will not dwell upon the perils which must result, both to life and property, from your first experiments with a gun; I pass over the trifling inconvenience of our compulsory residence in the cellar while you broke every pane in the house; but I pause to ask you how you dare to propose the murder of those sweet musicians, who not only sing for you as you work, but eat your grubs and wireworms by the bushel? Cover your cherries with nets, Joseph Grundy—and your head with shame! You are worse, I declare, than that dull yahoo from the mining districts, who, coming to spend a few days in the country, 'could not sleep o' nights for them nasty nightingales.' Shall I take our cage to Verjuice, and order her to make you a canary dumpling? or would you prefer that four-and-twenty blackbirds be forthwith baked in a pie? Seriously—do those birds no hurt. 'Taught by a Power that pities me, I learn to pity them,' and I commend the lesson to you."

Then her neat figure, in its grey silken dress, moved away upon the gravel homewards; and he was left lamenting. And now befell a visitation, too common in an unloving world; a lancer rode forth to prick the wounded; a donkey came to kick the ailing lion. Like a pirate upon some helpless wreck, sweeps down Mrs. Verjuice upon Joseph's grief. With bad taste and worse grammar, she announced her solemn conviction that it was his, Joseph's, desire and aim to break his mississes arts; and it was her opinion, though she judged no one, that he was in Co. (by which she meant in partnership) with most of the internal powers; and she only hoped he might not some day find himself where the worm never should be quenched. This and much additional rubbish she discharged with great volubility, and then, imitating her mistress, retired with dignity.

But distinct and separate, as the orators themselves, were the effects of the two orations. Miss Susan's speech left her hearer sad, ruthfully penitent concerning the blackbirds, and as thoroughly ashamed of the subject, as the Ancient Mariner must have been of the albatross hung about his neck. Mrs. V.'s remarks appeared, on the contrary, the rather to cheer and comfort him; and he so far regained his animal spirits as to wink, when she finished, to an attendant robin (presiding, like an Emperor, over his Diet of Worms, hard by), and pointing with his thumb to her retreating form, to murmur,

"Poor old runt."

They are good friends, nevertheless, these two fellow-servants; and Sleet and Sunshine, as Miss Mary calls them, enjoy together life's April day. "When the old gal is on the big," says Grundy—irreverently alluding to those seasons in which the lady's temper is especially acutose, her observations of the pointed order; and her enunciation so exceedingly

* "The Life of Patrick Fraser Tytler."

nimble, that, as Schiller said of Madame de Staél, "a man must be all ear to follow her"—when the old gal is on the hig, I never counterdx nothink. Beautiful, says I, as if I were admiring of a pin-wheel; and off she goes, just like one, a blazing, and fizzing, and spluttering, till all her gunpowder and brimstone's burnt out, and she stops as still as a hystor." Artful Joseph shrewd in thy reticence, as the monk Eustace with Elspeth Glendinning, when he remembered that a woman of the good dame's condition was like a top, which, if you let it spin untouched, must at last come to a pause; but, if you interrupt it by flogging, there is no end to its gyrations!

At an earlier period of their acquaintance, Joseph had essayed by various demonstrations to inform to Mrs. V. that her monologues were a little tedious, yawning, with extended arms, and consulting his watch from time to time in a very anxious and ostentatious manner. Such a watch! After an entire derangement of the owner's vest, a liberal display of brace and button, and some powerful tuggings at a steel chain, out it came from its well, like the diving-bell at the Polytechnic. Mr. Chiswick pretended to covet the case, as "a sweet tank for the Victoria Lily," and affirmed that when Grundy travelled on the rail, his timepieces was charged as extra luggage. But the exhibition of this huge chronometer, displayed and branched as some intimation that Time was on the wing and precious, by no means produced the effect proposed. "The old mare" (you must really excuse Joseph's stable mind) "began to rear and plunge like anything; and says I to myself, this here's a hanimal, which she'll stand no ticklings by whips nor straps, and if you dont give her 'ed, Joe Grundy, you'll be having her heels through your splashboard!"

If evidence were required to show the prudence of these reflections, and I wished to demonstrate the happy consequences of allowing the old mare her head, I should point triumphantly to the scarlet "comforter," which, coming through foul weather to "The Six of Spades," Mr. Grundy is wont to wear, and which was wrought expressly for him by the swift needle of Verjuice. Mr. Oldacres never beholds this neckerchief without addressing an inquiry to the Curate (of whom anon, my readers) "whether he is aware that one of the Society has serious thoughts of petitioning Parliament to legalise marriage with grandmothers;" and then he will address the brother in question, and promise him a dish of "the Duke's Potatoes," whenever they are needed for the wedding feast.

But what does he mean by "the Duke's Potatoes"? A good many years ago, when Joseph Grundy first came among us, with horticultural experiences of a very limited range, he was invited to attend a general meeting of our Floral and Cottage-gardening Association. The proceedings terminated with a supper, and at this supper were handed round some Jerusalem Artichokes, which Mr. Oldacres had kindly sent from the Castle. Now Joseph is a very impartial feeder, accepting all things (I was compelled on one occasion sternly to reprove a facetious waiter, whom I caught winking at his assistant, as he offered to my friend the sweet pudding-sance, and watched him pouring it liberally all over his boiled rabbit)—and he now helped himself accordingly. Presently an expression of extreme disrelish passed over his rosy face, and beckoning to the landlord of our village inn, the Gunter of our feast, he asked disdainfully, to be informed, "Whose swilltub he had robbed o' them things?" The reply was, that they had come from the Castle, a present from Mr. Oldacres. A momentary surprise and hesitation flitted over Mr. Grundy's lineaments, and then he spoke bravely, as he ever does, his thoughts:—"Duke or no Duke, if poor ould chap gets no better tatus nor these, he'd be foine and pleased with a Turnip!"

Hence the allusion of Mr. Oldacres. But Joseph is generally ready for him with some amusing rejoinder, and is never indeed to be lightly regarded as an adversary in jest and banter. There came a stranger to one of our meetings, I forget by whom introduced, and who must have possessed, if phrenology be true, so large an organ of self-esteem as considerably to perplex his hatter. This gentleman was pleased during the evening to turn his attention to Joseph Grundy, and, rightly inferring from his appearance that he was not a highly scientific gardener, to inquire, in ridicule, "what Orchids he thought of exhibiting at the next Crystal Palace Show?" J. G. took four long pulls at his pipe, and then answered very

meekly, "I have n't no Orchids, if you please, sir, and I'm not much of a shower; but I think I know what prize you'll win, sir." "Indeed," said our visitor, evidently pleased with the notion that his fame as a florist was known to us all; "and which may that be?" "Well," said Joseph, "thout' be first i' Cockscombs, and thout'nt not be very far behind i' Greencs."

And now that I have brought Spade No. 4 in safety back to our club-room, let me express the hope that he has not wearied you; and let me introduce you to his Reverence, the Curate.

(To be continued.) S. R. H.

THE GARDENING OF THE HUGUENOTS.

As a contribution to the early history of cultivation, the following article from Mr. Smiles's work on "The Huguenots" will be found interesting:—

At page 46 we read:—"Among the first things the Flemings did on arriving at Sandwich, was to turn to the best account in gardening the excellent qualities of the soil in that neighbourhood." Though long before practised by the monks, gardening had become almost a lost art in England, and it is said that Katharine, Queen of Henry VIII., unable to obtain a salad for her dinner in all England, had her table supplied from the Low Countries. It is reported that vegetables were formerly so scarce that they were salted down. Even in the sixteenth century, according to Foxe's "Life of James II.," p. 205, a cabbage from Holland (save the mark) was deemed an acceptable present. Hull then carried on a thriving import trade in cabbages and onions. The rarity of vegetables in this country may be inferred from the fact that in 1595 a sum equal to twenty shillings was paid at that port for six cabbages and a few carrots, by the purveyor of the Clifford family. (Whitaker's "History of Cromer," p. 331.) Harttel, writing in 1630, says, that an old man, then living, remembered the first gardener who came into Surrey to plant cabbages and cauliflower, and to sow turnips, carrots, parsnips, and early peas, all of which at that time were great wonders, we having few or none in England but what came from Holland and Flanders. It is also supposed, though it cannot be exactly ascertained, that the Protestant Walloons introduced the cultivation of the hop into Kent, bringing slips with them from Artois. The old distich,—

"Hops, Reformation, Bays, and Beer,
Came into England all in one year."

marks the period (about 1524) when the first English hops were planted. There is a plot of land at Bourne, near Canterbury, where there is known to have been a hop plantation in the reign of Elizabeth. Another kind of crop introduced by the Flemings at Sandwich was canary grass, which still continues to be grown on the neighbouring farms, and is indeed almost peculiar to the district. It may be added that to this day the "Sandwich celery" maintains its reputation. Mr. Smiles continues:—"The first Flemish gardeners proved highly successful. The cabbage, carrots, and celery produced by the foreigners met with so ready a sale, and were so much in demand in London itself, that a body of gardeners shortly removed from Sandwich and settled at Wandsworth, Battersea, and Bermondsey; where many of the rich garden grounds first planted by the Flemings continue to this day the most productive in the neighbourhood of the metropolis." Again, treating upon subsequent events, Mr. Smiles, speaking of the refugees at Portarlington in Ireland, observes (p. 383), "that the dwellings of the strangers were distinguished for their neatness and comfort; and their farms and gardens were patterns of tidiness and high culture. They introduced new fruit trees from abroad; amongst others, the black Italian walnut, and the Jargonele pear—specimens of which still flourish at Portarlington in vigorous old age. The emigrants also introduced the espalier with great success, and their fruit became widely celebrated. Another favourite branch of culture was flowers, of which they imported many new sorts, while their vegetables were unmatched in Ireland."

Again, at page 413, it is remarked of the French handloom weavers, who introduced the silk trade into Spitalfields and other places, that while their domestic habits were the purest and their industry unboundedly, they indulged in simple pleasures, and were especially noted for their love of flowers. They vied with one another in the production of the finest plants; and wherever they settled they usually set up a floricultural society to exhibit their products. Among the first societies in England was that established by the exiles in Spitalfields; and when a body of them went over to Dublin to carry on the manufacture of poplins, they proceeded to set on foot the celebrated flower club which still exists in that city. Others of them, who settled in Manchester and Macclesfield, carried thither the same love of flowers and botany which still

continues so remarkably to characterise their descendants. At page 431 it is stated that there are still some of their old mulberry trees to be seen in the gardens near Spital Square. One of the streets too, is named Vine Street—probably from the culture of the vine by the refugees. In a recent letter to the *Times*, the Rev. Isaac Taylor says, that in addition to the many names and surnames and their traditions, the only relic which these exiles retain of their former prosperity and gentle nurture is a traditional love of birds and flowers. Their rooms, however-wretched, are decorated with a sickly plant, struggling, like its sickly owner, for bare life; or a caged bird warbling the songs of heaven to the poor imprisoned weaver as he plies his weary labour.

The Huguenots were farmers as well as gardeners. They introduced improved modes of husbandry, and were the first to turn their attention to the cultivation of waste lands. In Languedoc the cantons inhabited by the Protestants were the best cultivated and most productive. The vine dressers of Beris and the Pays Messin on the Moselle restored those districts to more than their former prosperity; and the diligence, skill, and labour with which they subdued the stubborn soil and made it yield its increase of flowers and fruit and corn and wine, bore witness in all quarters to the toil and energy of the men. Indeed, it is impossible to exaggerate the influence of these exiles upon the industry and household economy of our country.

THE ARBORETUM.

HARDY TREES AND SHRUBS.

THE BEAUTIFUL NEPAL SPIREA (*SPIREA BELLA*).

This is a native of Nepal and Bhootan, where it is found in ravines and mountain woods, at an elevation of from five thousand to nine thousand feet. It is perfectly hardy, grows freely in any common garden soil, and is easily increased either by cuttings, or by means of suckers, which, if separated in the autumn, soon make nice plants. It was first introduced in 1820. No garden, however small, should be without it.

It forms a beautiful open, and rather loose-growing shrub, from three to four feet high, which throws up strong shoots annually from the ground, that, in the following season, produce laterals, terminated with loose corymbs of pretty deep rose-coloured flowers in May and June. The leaves are alternate, on longish footstalks, ovate, acutely pointed, sharply serrated, light green, and smooth on the upper surface, somewhat glaucous beneath, with the peduncles and principal veins on the under side pubescent. The stems are somewhat diffuse, flexuous, reddish, and branching; branches, loose, slender, spreading, and downy. The fruit, which is composed of five reddish, shining carpels, is ripe in September.

The late Mr. Loudon called it "a very beautiful species, which every cottager ought to have in his garden."

THE NEPAL WHITE BEAM TREE (*PYRUS VESTITA*).

This forms a splendid small tree from twenty to thirty feet in height, which flowers in May and June. It is a native of Kamaon and Upper Nepal, at elevations of from nine thousand to twelve thousand feet, and was first introduced in 1820. The leaves are very large, ovate-acute or elliptic, acutely serrated or coarsely serrated towards the points, on rather long footstalks, and when they first appear, which is very late in the season, they are clothed with a thick white coating of wool, but as soon as the warm weather advances, they throw off their fleecy coat on the upper surface, and at length become smooth and of a glossy green. In the autumn, before they drop off, they assume a fine pale yellow colour. The branches are whitely tomentose when young, but smooth when old. The flowers, which are numerous, and white, are borne in branched terminal woolly racemose corymbs. The fruit is round, tubercled, glossy, and about the size of a common marble, and greenish brown when ripe in October.

The subject of adapting the size of trees to the extent of the grounds in which they are to be planted, is one which is very generally neglected, notwithstanding its great importance; for almost every one who plants a garden of a few rods in the neighbourhood of London, finds in eight or ten years afterwards that a few of the coarser-growing trees have attained to such a size as to smother everything else, and to render it altogether impossible either to have smooth turf or healthy flowers. Now the *Pyrus vestita* is one of those small trees which are most suitable for planting in such places, not only on account of the beauty of its foliage, but also on account of its growing rapidly till it attains a height of from fifteen

to twenty feet; then it becomes comparatively stationary for many years.

The following are the synonyms under which it is often sold:—*Pyrus crenata*, *lanata*, and *nopaleensis*. G. Gordon, A.L.S.

Tree-wives.—I must tell you about some of my tree-wives. I was at one period of my life much devoted to the young lady-population of Rhode Island, a small, but delightful State in the neighbourhood of Pawtucket. The number of inhabitants not being very large, I had leisure, during my visits to the Providence Plantations, to inspect the face of the country in the intervals of more fascinating studies of physiognomy. I heard some talk of a great elm a short distance from the locality just mentioned. "Let us see the great elm," I said, and proceeded to find it; knowing that it was on a certain farm in a place called Johnston, if I remember rightly. I shall never forget my ride and my introduction to the great Johnston elm. I always tremble for a celebrated tree when I approach it for the first time. Provincialism has no scale of excellence in man or vegetable; it never knows a first-rate article of either kind when it has it, and is constantly taking second and third rate ones for Nature's best. I have often fancied the tree was afraid of me, and that a sort of shiver came over it as over a betrothed maiden when she first stands before the unknown to whom she has been plighted. Before the measuring-tape the proudest tree of them all quails and shrinks into itself. All those stories of four or five men stretching their arms around it and not touching each other's fingers, of one's pacing the shadow at noon and making it so many hundred feet, die upon its leafy lips in the presence of the awful ribbon which has strangled so many false pretensions. As I rode along the pleasant way, watching eagerly for the object of my journey, the rounded tops of the elms rose from time to time at the roadside. Wherever one looked taller and fuller than the rest, I asked myself, "Is this it?" But as I drew nearer, they grow smaller, or it proved, perhaps, that two standing in a line had looked like one, and so deceived me. At last, all at once, when I was not thinking of it—I declare to you, it makes my flesh creep when I think of it now—all at once I saw a great, green cloud swelling in the horizon, so vast, so symmetrical, of such Olympian majesty and imperial supremacy among the lesser forest-growths, that my heart stopped short, they jumped at my ribs as a hunter springs at a five-barred gate, and I felt all through me, without need of uttering the words, "This is it!"—*The Autocrat of the Breakfast Table.*

THE TIMBER FORESTS OF THE ANDAMAN ISLANDS.*

MR. KURZ, Curator of the Herbarium of the Royal Botanic Gardens of Calcutta, was directed by the Government of India to proceed to the Andaman Islands (now, unhappily, brought into prominent notice by the sad death of Lord Mayo), and, in order to prepare a detailed report of the nature of their vegetation, he visited most of the eastern coast, as far as Macpherson's Straits and Rutland Island, and afterwards explored the Labyrinth Islands, and a good part of the western coast, as far as Port Campbell. Mr. Kurz next proceeded, on board the *Diana* steamer, northward, along the eastern shore, as far as Middle Straits. On the 11th of May, however, when on the point of starting to explore the interior of South Andaman from Escape Bay, Mr. Kurz was seized by the Burmese convicts who had been assigned to him as servants to aid him in prosecuting the exploration of the island. Having tied him hand and foot, these good and faithful servants left him lying on the ground in the jungle, and effected their escape. Mr. Kurz, though thus deserted, succeeded in reaching the coast in safety; but this mishap, combined with subsequent circumstances, compelled him to relinquish the further prosecution of the intended explorations, and he unwillingly returned to Calcutta, leaving a great part of the work assigned to him uncompleted. His report of the observations he was enabled to make previous to his misadventure is, however, full of interest as far as it goes; and it is to be hoped that he will be enabled on a future occasion to complete his botanical survey of the islands under more fortunate conditions, and especially at a more fitting season of the year. The hot and dry months—March, April, May, and part of June—were found, when too late, exceedingly unfavourable for botanical explorations; the herbaceous plants being scorched up almost beyond recognition, and the deciduous trees entirely bare of flowers, fruit, or even foliage. Mr. Kurz arrived at the conclusion, seeing that the heavy rains occurred in July, August, and part of September, that October, November, and December would

* Condensed from the "Blue Book" Reports of the East India Forest Conservancy.

be the most favourable for his purposes; and it is possible that a future expedition may be made at that season.

The following summary is a condensed abridgement of the detailed report submitted by Mr. Kurz to the Government of India in 1868, with several additions and corrections subsequently appended. The whole of South Andaman was found to be hilly, and almost mountainous on the eastern coast, but having a good extent of level land on the western side. Rutland Island, however, rises gradually into a central mountain, which attains the height of about two thousand feet.

The diversity of soils of South Andaman, considering the extent of the island, is very great. Over decomposed serpentine rock a brick-coloured soil is invariably found. A yellowish clay follows the course of the sandstone formation, and is the most extensive and important of the soils. A greyish black soil, full of siliceous particles, follows on the greenstone rock, while a black humous soil is predominant in the valley, and especially on Termele Island, where the Kuppalee trees flourish in great luxuriance. According

except in the rainy season, which sets in in the middle of May, is tolerably dry. During the rains the temperature falls occasionally to about 75°. In the middle of July the continuously heavy showers cease, and rain generally falls only on alternate days, or after two or three days' interval. This weather, Mr. Kurz was informed, continued, with little variation, till January and February, when the hot, dry season sets in. It appears that, since considerable forest clearings have taken place, the occurrence of the spring rains has been retarded by about half a month.

The general botanical aspect of the eastern coast of South Andaman is richly picturesque, the hills being in many parts densely clothed with forests of finely-grown trees, running up with a straight stem to a height of one hundred feet or more, many of them forming the support of climbing plants, which, reaching the summit, hang in leafy drapery, and form gigantic festoons from tree to tree, where they put forth their various and brilliantly coloured flowers far above the reach of man. Among these climbers *Dinocloea*, *Calamus*, *Dischidia*, and others may be recognised. At Corbyn's Cove the

An Indian Forest.

to the degree of moisture there these soils are more or less mingled with decayed vegetable matter, and in consequence more or less fertile.

From observing stumps of trees rising from the sea near the coast, Mr. Kurz came to the conclusion, after careful investigation, that the Andaman Islands are slowly sinking, and that the submerged land in which these stumps are still standing, formed, at a comparatively recent period, high and dry land, many of these stumps being found to belong to species which never grow in mangrove swamps, nor in any locality such as that in which they are now standing. They were *Pongamia*, *Erythrina*, *Thespis*, *Mimosa*, *indica*, and *Bruguiera gymnorhiza*. It is, in fact, known that the sea has encroached from forty to fifty feet at Chatham Island, in Port Cornwallis, where the storehouse has been destroyed by the sea since the abandonment of the place in 1796; while a similar encroachment is now in progress at Port Blair.

The temperature in South Andaman in April is 86° to 87° at six in the morning, and about 91° in the middle of the day. Even in the night the thermometer seldom falls below 85°. The atmosphere,

vegetation of the deciduous trees becomes more stunted, rarely exceeding eighty feet, and other trees are of less straight growth. The general verdure, however, becomes brighter after the rainy season, long tracts occurring with leaf-shedding trees which are found also among the predominating evergreens of the forests.

In the mangrove swamps *Rhizophora* and *Ceriops*, with their glossy foliage, fringe most of the little bays and straits, and *Phoenix paludosa* is a characteristic feature all along certain parts of the coast, *Barringtonia* and *Excoecaria Agallocha* being conspicuous by their red decaying leaves in June and July. *Lagerstroemia* and *Pterocarpus* exhibit profusely in their season their rich lilac or yellow blossoms; and *Mussenda*, with its snow-white calyx segments, forms a remarkable feature in the botanical array. A large *Crinum*, with broad leaves, appears abundantly along the sandy parts of the shores; while arborescent *Euphorbiaceæ* impart a singular character to the coast scenery; and Screw Pines and a kind of *Cycas* of considerable height carry the imagination back to the earlier geological epochs. Most varied tints of green may be everywhere seen among the forest

mass, and suggest the existence of a most luxuriant flora, which, however, is only developed during the rains.

The mangrove vegetation is most remarkable about the flat shallows of Mangrove Bay and Middle Straits, extending into the sea as far as low-water mark. The trees get higher towards the land and up the banks of the creeks, and they attain the height of eighty feet when supplied with fresh water instead of salt. *Carapa obovata* is the most curious feature among these mangroves, and is often quite covered with the still more curious *Hydnophytum formicarium*, the tubers of which attain an enormous size. Among the most frequent orchids of the region are *Eria Kurzii*, *Pholidota imbricata*, *Dendrobium crumenatum*, *Oxystophyllum*, *Cleistostoma*, *Cirrhopteridium Andersonii*, and *Bulbophyllum*; and among the most conspicuous climbing plants are a handsome *Hoya* and *Dischidia*. It was observed that the rough bark of the trees was almost entirely clothed with a great variety of cortical lichens. A coarse glaucous *Cyperus*, *Acanthus ilicifolius*, and *A. obtractatus* were almost the only phanerogamic perennials observed growing in the swamps.

At a certain point in the Middle Straits on both shores the palms *Phoenix paludosa* and *Lacistema paludosa* suddenly appear in great abundance, occasionally mixed with mangroves, but usually growing in the rear of them; and *Fimbristylis andamanica* was found abundantly near the same point, but nowhere else in South Andaman.

In places where from the steepness of the shore there is no swamp, and mangroves do not find a congenial habitat, a zone of vegetation of another kind occurs, consisting chiefly of *Thespesia populnea*, *Hibiscus tiliaeus*, *Pongamia glabra*, *Erythrina indica*, *Guettaera speciosa*, *Heritiera littoralis*, *Pandanus tectorius*, *Cycas Rumphii*, and many other plants usually found in similar situations in the tropics. *Calophyllum inophyllum* of enormous size was also observed; and among the more conspicuous climbers of the region are *Ipomoea campanulata*, *Mucuna gigantea*, *Brachypterum scandens*, *Entada Purpurea*, and several kinds of vines. *Ipomoea pes caprae* sometimes forms a striking feature near the sea, and there are various creeping grasses, such as *Ischaemum muticum*. Among the Ferns of this part of the coast, *Polypodium querleoides* was observed in great profusion on the branches of trees standing near the sea. Immediately behind the seashore zone of vegetation a greater variety occurs, and several plants were observed which until now were only known from southern India, such as *Freyincinia*, *Anaxagorea*, *Dinchozia*, &c.

The evergreen forests are most extensive in the Andaman Isles, but most difficult to penetrate, in consequence of the rank growth of gigantic climbers, such as, climbing bamboos and prickly canes with terribly strong and sharp thorns, the growth of climbing plants of this kind being fostered by the warm moisture and congenial shade furnished by the evergreen foliage of many of the great forest trees. Those forests, which Mr. Kurz indicates as Kuppalee forests, occupy the land at the mouths of creeks and the zone immediately behind mangrove swamps. Sometimes they consist almost entirely of *Kuppalee* (*Mimusops indica*), a tree ranging generally from seventy feet to eighty feet, with a girth of twelve feet to fourteen feet, and growing up as straight as *Dipterocarps*. The Burmese name of this tree (Kuppalee) signifies "tree of the Andamans." *Calophyllum inophyllum* and *Hermodia*, and also *Macaranga indica*, are occasionally found associated with the *Mimusops*.

Farther inland the more mixed forests begin, in which the typical tree is *Dipterocarpus laevis*, the other and far less predominant trees being *Dipterocarpus alatus*, *Mesa ferrea*, *Lagerstroemia hypoleuca*, *Pterocarpus Dalbergioides*, *Iringa glabra*, and several others; and, at this season (April), there often appears a group of leafless *Bombax malabaricum*, *Tetrameles nudiflora*, and some other leaf-shedding trees.

Under the protection of the more lofty trees, others of smaller growth occur in abundance, such as *Myristica* and the delicate *Baccaurea sapida*, *Mangifera sylvatica*, several *Tethranthorae*, a large-flowered *Mussaenda*; and a number of other rubiaceous trees are also tolerably abundant. Beneath these the shrubby under-wood, which is extremely dense, is difficult of classification in a general statement; but it may be stated that among the most common are *Claoxyylon*, *Rottlera*, *Glycosmis pentaphylla*, *Unona longiflora*, and *Grumilea elongata*.

The climbing vegetation comprises *Dinchozia Tjankorch*, several vines, *Thunbergia laurifolia*, *Uvaria sunatrana*, *Zizyphus Oenoplia*, several *Cucurbitaceae*, *Brachypterum scandens*; *Flagellaris indica*, *Gnotum scandens*, and so many others, in so much that it may almost be said that every family of tropical climbers has its representatives. They are so numerous, and of such robust growth, and many of them so formidably thorny, that, as before stated, they render parts of these forests, especially near the ridges, almost impenetrable.

Palms are numerous in the Andamans; and on Termekeo Island

a gigantic but stemless *Corypha*, with leaves thirty feet long, presents a most striking appearance.

The herbaceous vegetation, both annual and perennial, which is to be found during the dry season, is exceedingly scanty, and confined to about a dozen genera, the only real annuals which appear during the heats being *Urena lobata*, *Blumea virens*, and *B. myriophylla*.

Among the deciduous trees, which are leafless during the same period, are *Bombax malabaricum*, several kinds of *Sterculia*, *Calanthus indica*, *Albizia Lebbek*, *Ficus infectoria*, *Canarium euphylum*, and several others, which give those parts of the coast where they occur a bare appearance during three or four months of the year. But in June, when the rains bring them into leaf, various tints of red, brown, and yellow quickly enrich the buds, the fully developed foliage exhibiting the richest greens of various tones, while the broad, hemispherical crowns of the trees produce a most agreeable contrast to the more spiral growth of the evergreens. Owing to the little shade afforded by these deciduous trees during the hot season, climbers cannot develop their growth beneath them, and the regions of deciduous trees are, therefore, nearly free from them, the few that occur being of weakly and stunted growth. The immense buttressing of some of the large trees was specially noticed by Mr. Kurz, who states that trees having a girth of twelve feet at a height of eight or ten feet, may have a girth of forty feet close to the ground, in consequence of the vast ridges or vegetable buttress, by means of which the trunks are steadied and kept erect against the fierce wind of a cyclone.

The bamboo jungles, which form one of the leading features in the Andamans, were found by Mr. Kurz to occur invariably in connection with the indurated chloritic rocks; and wherever bamboo jungles appear, it may be safely inferred that chlorite rock or serpentine is present. The mean height of these bamboos is thirty feet to thirty-five feet, and they consist principally of *Bambusa andamanica*. In the midst of these cane jungles forest trees of the largest growth occur at distances of one hundred feet or so, and many of them reach a height of one hundred feet. *Dillenia aurea* and *Careya spharica* are the most common. These tall trees, when seen from the sea, stand out from the bamboos like slender palm trees from a low jungle.

The central portion of the forests of South Andaman remain still nearly a terra incognita, Mr. Kurz having penetrated into that region for a few hours only. The trees that he observed to be most numerous were *Dipterocarpus laevis*, *Dracontomelum*, two species of *Irina*, *Bassia caloneura*, *Chickrassia tabularis*, and others. The principal shrubs were *Alodia bengalensis* and *Unona longiflora*; the chief climbers being *Dinchozia*, several vines, and *Calamus*.

On Bird Islands the large number of orange-red fruits of the *Trichosanthes palmata* produce a rich and picturesque effect, looking like a number of bright-coloured balls suspended from the rocks.

In summing up his observations on the character of the Andaman flora, Mr. Kurz observes that its peculiarities do not consist in the presence of now and rare species, but rather in the remarkable absence of many of the common forms which are so abundant in the surrounding countries. Among the most important of these deficiencies is the total absence of *Magnoliaceae*, *Annonaceae*, *Umbelliferae*, *Vacciniaceae*, *Antirrhineae*, *Labiatae*, *Polygonaceae*, *Amarantaceae*, *Salicaceae*, *Cupuliferae*, *Coniferae*, *Pontederiacae*, *Hypoxidaceae*, and a number of smaller families. The absence of *Nymphaeaceae* and other aquatic families is to be accounted for by the great scarcity of water in the dry season. The extreme scarcity of annual plants and of so-called weeds beyond Port Blair is also one of the most remarkable features in the flora of the Andamans.

Of the importance of the Andaman forests in regard to trees valuable as timber, Mr. Kurz has obtained much interesting information, and yet he believes that in consequence of the circumstances which prevented the completion of his survey he is not yet acquainted with more than two-fifths of the different kinds of timber trees which exist in the several islands. The mean height of the largest forest trees he estimates at about a hundred feet, with a girth from eight to twelve feet. They occur from twenty to forty in an acre, but in the bamboo jungles there are not more than ten in a similar area. On the sandstone formation, *Dillenia aurea*, *Mimusops indica*, *Sterculia ornata*, *Pterocarpus Dalbergioides*, and a number of others; form immense trees from eighty to a hundred feet high, with a straight, unbranched stem like a wood-oil tree; but the same species are stunted and of inferior growth where the presence of chalk much influences them. Mr. Kurz remarks that we do not as yet possess a thorough knowledge of the relative value of the timber trees of British India itself, attention having been attracted to comparatively few kinds. Much less do we know of the value of the different kinds of Andaman timber, which must be tested by experiment before any trustworthy conclusions can be arrived at. No trees of such enormous size as are noted from Burma have been observed by Mr. Kurz in the Andamans,

The largest wood-oil trees which he measured did not exceed fifteen feet three inches in girth, with a height of one hundred and twenty feet, while Dr. Wallich notes them in his reports as having a girth of twenty-one feet four inches and being two hundred and fifty feet high.—No teak was found during Mr. Kurz's explorations, nor any timber of equal quality, except, perhaps, the Kuppalace (*Minusops indica*), of which there is vast abundance, and which yields the wood so much used for gunstocks by the Madras Ordnance Department, where it is known by the name of bullet wood. This tree grows with a straight stem to the height of eighty feet before it branches, the average girth being twelve to fourteen feet. It appears that at the lowest computation the forests abounding in trees of this genus occupy thirty square miles in South Andaman. The Kuppalace is esteemed by the natives as a very valuable timber tree, and it has been sold at fifty rupees a ton. For house building and furniture it may be found too heavy, but for machinery and railway work it is invaluable. Mr. Kurz recommends to the Indian Government the careful conservancy of the forests producing it, which are in the flat country near the coast, and easily accessible.

Among the trees yielding second-rate kinds of timber Mr. Kurz mentions the Pemah (*Lagerstroemia*), the Kengan (*Mesua ferrea*), the Padouk (*Pterocarpus Dalbergioides*), the Kokkok (*Albizia Lebbeck*), and also *Careya sphaerica*, which all occur in the high forests of the hilly interior.

Among the mangrove swamps the following trees are notable for their strong wood:—Penlay-cong (*Carapa obovata*), Pinlay-kanaaz or Soondreé tree (*Iheritiera littoralis*), and Beybo (*Bruguiera gymnorhiza*). All these trees occur in Burma, but are not worked, as teak, of which there is still a good supply, is deemed preferable. On the whole, Mr. Kurz does not recommend resorting at present to the Andamans for our Indian supply of timber, but the preservation of those forests he deems to be highly important, as the whole of the vitally important water supply and general moisture depends greatly on the preservation of large forests, so that every precaution should be taken to prevent needless and wasteful encroachments; a point strongly insisted upon by Mr. Dalzell, in his valuable report on the influence of forests, preserved in the records of the Bombay Government.

H. N. H.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Lopping Trees.—Some Birches, Laburnums, Acacias, and Weeping Willows obstruct the view between my windows and the public road. Can I, a tenant, lop off some of the offending branches?—J. MACLAREN.—[If you lop the trees without your landlord's consent he can bring an action against you for damaging his property.]

Killing Tree Stumps.—Your correspondent "W. T." in planting young trees on ground where, he says, the roots of the existing trees cannot be got out, has committed a mistake that will, in all probability, prove fatal to those he has planted. I never knew a single instance where a new plantation was made on ground that had been previously occupied with trees that ever succeeded, unless the whole of the ground was trenched over as deeply as the roots of the trees removed had gone, and every root, as thick as a person's finger, got out—an operation that costs as much as the ground is usually worth. The result is generally this: the young trees for a time grow, but in two or three years they begin to look sickly, and die off. On examining the roots, they are found to be destroyed by a fungus, which has done nature's work in assisting the decomposition of the dead roots, and, for want of a further supply of food, attacks the living ones, which, in turn, succumb to its encroachments.—T. BAINES, *Southgate*.

Dwarf Shrubs for Edgings.—Will you kindly give me a list of dwarf shrubs, &c., for permanently furnishing the margins of beds and masses of shrubs now naked in winter? I should like them dwarf and neat in habit.—DELTIA.—[The following will perhaps answer your purpose:]

<i>Andromeda floribunda</i>	<i>Eurycoma radicans</i> fol.	<i>Menziesia</i> , several kinds
<i>Arcostaphylos Uva Ursi</i>	<i>variegata</i>	<i>Ononis fruticosa</i>
<i>Astragalus Tragacantha</i>	<i>Gaultheria procumbens</i>	<i>rotundifolia</i>
<i>Azalea nummata</i>	<i>Shallon</i>	<i>Perenetyta</i> , several kinds
<i>Bryanthus erectus</i>	<i>Genista anglica</i>	<i>Polygalia Chamaebuxus</i>
<i>Caluna vulgaris</i> , in var. <i>varia</i>	<i>hispanica</i>	<i>Potentilla floribunda</i>
<i>Castilleja varia</i> species	<i>sagittalis</i>	<i>fruticosas</i>
<i>Corinus canadensis</i>	<i>tinctoria</i>	<i>Rhododendron</i> , many kinds
<i>Coloneaster microphylla</i>	<i>Helminthium</i> , many kinds	<i>Ruscus hypophyllum</i>
<i>" thymifolia</i>		<i>racemosus</i>
<i>Cytisus sessilifolius</i>	<i>Hydrangea</i> , several kinds	<i>Salix latifolia</i>
<i>Daphne alpina</i>	<i>Hypericum calycinum</i>	<i>reticulata</i>
" <i>collina</i>	<i>Indigofera Dossia</i>	<i>Santolina Chamœcypterus</i>
" <i>lanceolata</i>	<i>floribunda</i>	<i>viridis</i>
<i>Empetrum nigrum</i>	<i>Ivies</i> , in great variety	<i>Skimmia japonica</i>
<i>" rubrum</i>	<i>Juniperus</i> , several kinds	<i>" laurocerasus</i>
<i>Epinops repens</i>	<i>tamariscifolia</i>	<i>oblate</i>
<i>Erica</i> , all hardy species	<i>Kalmia latifolia</i>	<i>Spiraea</i> , several kinds
<i>Euonymus japonicus</i> fol.	<i>nana</i>	<i>Vaccinium</i> , 3 or 4 kinds
<i>argentea</i>		<i>Vinca</i> , various kinds.]
" <i>nanus</i>	<i>Mahonia aquifolium</i>	

Hybrid Conifers.—Have any of your readers tried, now we have cone-bearing trees of *Abies Douglasii*, *nobilis*, &c., to raise hybrids between *A. pectinata* and these beautiful conifers? Such hybrids would probably be much hardier than their parents, and would be of great value in our climate, where even *Nordmanniana* was killed last winter in low situations in Bavaria.—OTTO FORSTER, *Aueburg*.

Mistletoe Growing on the Oak.—But few authentic instances of the common mistletoe being found growing spontaneously on the oak in England are to be found on record; the most reliable is that by the late Mr. Donald Beaton, who, in March 1837, exhibited at one of the meetings of the Horticultural Society in London a branch of the common oak, with two plants of ordinary mistletoe attached to it, and which had been found growing on the estate of Lord Somers, at Eastnor Castle, near Ledbury, in Herefordshire, by Mr. Moss, then the gardener there. The oak tree on which the mistletoe was found had several large plants of the parasite upon it, and was the only instance known to Mr. Moss, although he had made diligent search through a large extent of oak woods and other plantations in which mistletoe abounded on other kinds of trees; he, however, had noticed mistletoe growing on that particular oak for more than fifteen years, and he also remarked that the oak on which it grew was close to a large willow loaded with the parasite, and from which, no doubt, it had escaped.—G.

GARDEN DESTROYERS.

BULLFINCHES.

THERE are very few gardens or orchards in this part of the country that altogether escape the depredations of Bullfinches. Except in a slight weakness for raspberries, these birds are not particularly troublesome during the summer, but when winter fairly sets in they leave their woodland haunts and visit with undesirable frequency the neighbouring gardens and orchards, blighting without scruple the hopes of the gardener by removing with marvellous expertness and rapidity the blossom buds of his cherished trees. Just when winter is leaving us, and the days have perceptibly lengthened, and we may notice that the buds of the early plum trees have begun to feel the influence of the season by a slight expansion of their substance and by the relaxing grasp of the imbricated scales that hold the embryo blossom—at this moment more than any other we are pretty sure to have the self-betraying piping note of the Bullfinch sounding in a satisfactory key from the plum and cherry orchard; and we know from experience that our chance of crops of fruit from these trees will be small indeed if prompt measures are not taken to drive off these marnauds.

During the winter and before the pairing season, Bullfinches move about in small family parties of five or six members—probably the parent birds and the nestlings of last season. Knowing something of the social habits and instincts of these birds, we are pretty well assured that the discovery of a good store of sweet fruit-buds will not be preserved as a secret in the family circle, but will be confided to the very extensive range of acquaintances birds in general and Bullfinches in particular seem to possess. Hence the best, and in the end the most merciful, course to pursue is to effectually terrify or destroy the first flight that appears amongst the fruit trees. The attempt to frighten by means of blank cartridge may proceed the more decided course which involves a certain expenditure of No. 8 shot. We have tried to keep Bullfinches from our trees by interlacing white thread amongst the branches and by dusting the buds with soot and lime; but in each case the birds gave us to understand that they saw through such flimsy pretences by devoting themselves more particularly to the trees operated upon.

In the open woods we can well believe that the removal of a certain portion of the buds from the wild fruit trees—cherry, plum, and thorn—tends to repress and restrict the profusion of growth and excess of fruitfulness that, without the corrective action of birds and insects, might ensue. When we enter upon the scene, it but too often happens that we disturb the order and economy of nature by capricious acts of destruction or by injudicious favour. The merciless extinction of hawks has led to an undue increase in certain tribes of small birds, that of the Bullfinch among others. Were this not the case, the Bullfinch might have been recognised, in their diminished numbers, as birds of positive utility, both in the forest and orchard, and be named as benefactors, instead of being included among "garden plagues."

W. INGRAM, *Belvoir*,

THE NEW VINE PEST.

(PHYLLOXERA VASTATRIX).

DR. LICHTENSTEIN states that this pest is still continuing its ravages in the south of France; and that after having destroyed almost all the vines in the department of Vaucluse, and a very large part of those of Bouches du Rhône and du Gard, it has made a descent on the vineyards of l'Hérault, on several points simultaneously. It, however, does not attack all vines alike; it has a marked preference for some particular kinds, and of those it does attack, it does not carry on its ravages on all in the same way. He saw at Bordeaux a vineyard where the proprietor, M. Laliman, had brought together numerous varieties of American vines alongside those of the district. There are, as most people know, hundreds of varieties of vines in France; so are there in America; but they are all derived from three typical species, of which one is European, the *Vitis vinifera*; and two American, the *Vitis cordifolia* and *Vitis labrusca*. Now, from what he had himself seen, and from the observations of M. Laliman and Mr. Riley (for America), it has seemed to him to result that the *Vitis vinifera* is attacked through the roots, the *Vitis cordifolia* through the leaves, and the *Vitis labrusca* is not attacked either through the leaves or the roots. Starting from this, he suggests that the ravaged vineyards should be replanted with stocks of *Vitis labrusca* (whose roots would be safe), on which might be afterwards grafted the plants of the country (whose leaves would be safe). The *Vitis vinifera* alone has the elegant form of our deeply-cut vine leaves, with which everyone is familiar. The *Vitis cordifolia* has coriacous leaves, formed like the leaf of the ivy. Its foliage is sombre above, veined below. The *Vitis labrusca* has the leaves soft denticated, shaped like the leaves of the lime or sometimes of the maple. Its foliage is a tender green, and of a uniform grey and a little silky below. M. Lichtenstein adds he is far from maintaining his hypothesis against all comers or as one incapable of contradiction; a caution wisely given, because it seems to have been well ascertained that the Phylloxera passes from the leaves to the roots of the same plant. Mr. Riley (in 1870) stated, with ample details, that he had ascertained beyond doubt that after it has eaten up the leaves, or after they have fallen, it migrates to the roots below, there casting their skin and assuming a slightly different form (more tubercular than before). But it would appear that M. Lichtenstein has satisfied himself that the mischief done by this migration is slight, and different from that done by the insect when it settles to the root in the first instance. "A fact exists," he says, "which is, that in a vineyard which has been attacked, one kind of vine dies because it is attacked by the roots—it is the French one; another suffers because it is attacked by the leaves; in summer, and by the roots (but feebly) in winter—it is the cordifolia; and its descendants; a third resists and grows vigorously—it is the labrusca and its varieties." We agree with M. Lichtenstein that, at all events, his plan is surely worth trying.

A. M.

ANTS AND APHIDES.

PERMIT me to thank Mr. E. Newman for disposing of that mischievous fallacy that ants eat or destroy aphides. On this assumption many cultivators have welcomed ants as their best allies, thus harbouring two evils on their plants instead of one. There is no longer any doubt that the ants and aphides are sworn allies, unitedly bent on the discomfiture and defeat of cultivators. Each rather formidable by itself, they become well nigh inexterminable when associated together. For instance, the locomotion of the aphis in its most ravenous state is comparatively slow; and the space between plants is to it an impassable gulf. But can any one insure any part of a plant, in any place, against the visitation of a daring ant, either with or without wings? Their skill and daring carry them anywhere—everywhere; and they take the flies, green or black, with them. Again, tobacco smoke or water deals death to the aphides; but the ants seem rather to enjoy a smoke than otherwise, and nothing weaker than arsenic seems to disagree with them, either outside or in. Further, I believe the ants not only hide up or guard the aphides from each other, and thus establish new colonies, as Mr. Newman points out, but that they likewise shelter them in their earth casemates in times of danger. On fumigating plant-houses where both abound, the ants seem to be all excitement at first; and it is no uncommon occurrence to see them forewarning the aphides of their danger, gently agitating and driving them off, as Africans do their cattle when an enemy is at hand, and carrying off the more lethargic to a place of safety. Again, when the tobacco-sick aphides fall down on the surface, there are their friends the ants waiting ready to receive and bury them. The earth is heaped over them, not to cover the dead but resuscitate the living. This slight covering of earth shuts out the smoke, and they quickly revive. Even when the aphides are too

sick to fall down in a fainting fit, the ants are equal to the emergency, and mount up the stems or leaves, where their distressed friends most do congregate, with bits of earth wherewith to protect them. And such earth shields are effectual, and the aphides emerge from the casemates hungrier and more ravenously destructive than before.

And then as to the milking of the ants. I have no doubt it increases their capacity for sap sucking. This explains another fact with which I have long been familiar, but the reason of which I could not comprehend till now, that is, that aphides and ants together always seemed to do more mischief than the aphides alone; and yet the ants never appear to do anything but dance attendance on the aphides. I should like Mr. Newman's opinion on this point. But my previous observations would lead to the conclusion that the oftener the aphides are milked the more they eat, hence, the more ants the more destructive the aphides. It is quite certain that the aphides like the attendance of the ants. It was the apparent pleasure they manifested under their manipulations that first convinced me that they did them no injury.

The simultaneous appearance of ants and aphides is a very curious phenomenon, and might suggest the inquiry at times of whether the aphides do not carry the ants. Naturalists will tell us whether this is possible. If it is, I should certainly be prepared to believe that they do. This much is certain, that they tread upon each other's heels so closely that it is impossible at times to say which comes first. Of course this would be so, on Mr. Newman's supposition that the ants transport the aphides; but it would be a curious instance of reciprocal service in the insect world, could it likewise be shown that the aphides transport the ants in embryotic form.

A handy, certain remedy for the destruction of ants is still a desideratum, which I trust some of your readers will be able to provide. Boiling water and arsenic are fatal to ants; but the difficulty is to get the former on them without injury to the plants at root or top; and the latter they often refuse to eat, though treacled nicely to suit the supposed sweet tooth of the ants.

D. T. F.

MOLE HUNTING IN GARDENS,

An old man, well up in mole-lore, though not a professional molecatcher, like Warps (see Professor Owen's article on "Mole Hunting in Gardens," page 249); assured me that the best way to get hold of some moles that had proved very troublesome in a carnation border and adjacent flower-beds, was to watch for them and pitch them out. He added: "It is easily done, for moles only work periodically, and for a short time at each spell. Eight, twelve, four—night and day—are their working times, as regularly as the clock."¹¹ This seemed to me such a novel view of mole-working that I at once started to their haunts to test its accuracy. I had little faith in the stated-hour theory, so I went all unprovided for a hunt. I reached the ground just as the clock struck one of the working hours—I forgot which, at the moment. Presently, as if the clock had summoned the mole to duty, the ground was turned up in a fresh heap beside me. After the heap there followed a run. Quick as possible I followed the track with my hands; the mole, greatly wondering, doubtless, what it had got at its heels, did its best, and went ahead at a gallop. But fate was against it. It had to make and clear the way, and it loosened the earth for me; so, after an exciting chase, I overtook and caught him. I have seen a good many pitched out since then with a spade; but I believe my success with hands only, against the burrowing snout and short, stout fore-feet of the mole, is unique.

My chief object, however, in writing, is to have it on the authority of Professor Owen, or some other gifted naturalist, whether the mole adheres to these periodical workings; and whether or not it devotes the same hours always to work, sleep, and play.

D. T. F.

[Professor Owen has kindly favoured us with the following remarks on this subject—"Moles," he says, "do work, with pretty regular intervals of rest, four or more times in the day; but not all at given hours. Your correspondent has drawn his conclusion from probably an accidental coincidence."]

Bees Destructive to Fruit.—In France, it is said, there are no greater pests to the fruit garden, especially to the grapes, than the common honey-bees. They are not content with levying a very handsome tithe, but they often devour no less than four-fifths of the crop, besides attacking all the best pears and apples. In short, they are much worse than wasps, as these are not abundant and troublesome every year, as the bees are.

Tenacity of Life in Cockchafer.—M. le Marchant, a pharmacien at Caen, has made many experiments on the tenacity of life in cockchafers when apparently drowned, and he has found that after complete immersion for a considerable period, if taken out of the water and exposed to light and air, they have still shown signs of life.

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from page 315.)

DOUBLE WINDOWS.

The following general rules may be found useful in the case of plants grown in double windows:

1. When the mercury stands below the freezing point, the ventilators should not be opened.

2. During hoar frost, if the wind strikes the window, the ventilators should be closed even if the mercury stands above 32°; as otherwise the immoderate influx of the wind cannot be prevented.

3. In mild, fine weather greenhouse plants may receive as much air as possible, but hothouse plants only so when the temperature outside is higher than that within, and when the air is calm and not too dry. In spring, before the greenhouse plants are placed out for good in the open air, the double window should be previously ventilated by day and by night.

4. In opening the ventilators from without, care should be taken not to open them too much, as too great an influx of dry summer air would destroy all the advantages which the double window affords. In summer, during stormy or very dry warm weather when ventilation from within is impossible, fresh air may be freely admitted through all the ventilators which have been made to open inwards.

5. The windows which open inwards should not be opened during dusty summer weather, nor when, in cold weather, the other windows of the room are opened.

SHADING.

In intimate connection with ventilation and the regulation

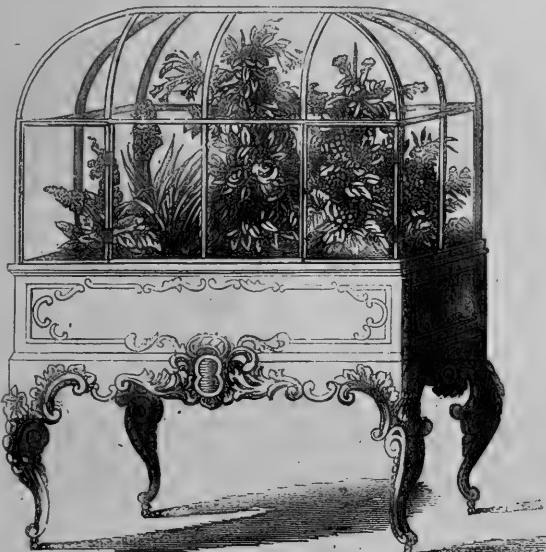

of the temperature stands the subject of shading. In bright, strong sunshine, when there is no ventilation, the temperature inside the double window is raised not only to a considerable degree, but it will also dry the air very much. If, at the same time, there is a flow of air, either from within or without, the greater number of greenhouse plants in the double window require no shading in the course of the autumn, winter, and

spring. But when, during constantly cold nights and clear, open sunny weather, greenhouse plants must be kept longer in their winter quarters, they may have a slight shading in spring by giving the outer window a thin coat of lime-wash. As soon as the weather becomes permanently warmer, greenhouse plants are put out for good in the positions intended for them in the open air, having been previously hardened off by the admission of air.

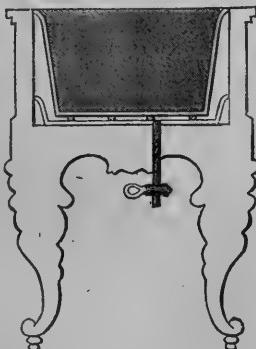

As the double window must always occupy a sunny position, it must always be artificially shaded when it is used in the end of spring and during the summer for the culture of tender hothouse plants. This shading may be effected either by means of lime-wash, as mentioned, or by suspending a covering of thin canvas, or some suitable material. The first method is the simplest, but it has this disadvantage, that it remains during gloomy weather, and then does not look well either from within or without. This disadvantage may, to some extent, be diminished by laying on as thin a coating as possible, so as to

break the force of the direct rays of the sun, and yet admit sufficient light.

The plants in a common double window are best shaded on hot and bright summer days by hanging a shade of sailcloth outside which can be raised and lowered by a cord. The same mode of shading may be used for the double window, only

Plant Case.

Section of a Plant Case.

here the raising and lowering of the shade must be from the outside, or the cord may be passed over rollers, and brought in through the frame of the window, so that the shade may be raised and lowered from within at any time when necessary. This arrangement is, of course, the best.

As the erection and maintenance of such a shade is always costly, we may suggest two other methods. The first of these resembles the limewash plan in being a permanent shade formed of some shading material fastened over the outside of the window. For this purpose wide-meshed muslin, or a shade woven of reeds, or twigs with interstices at least as wide as the width of the materials, is used. This shade, which is to remain fixed all the summer, and which merely breaks the force of the sun's rays, and yet looks better than the lime-wash, is first applied in spring, when there is reason to dread that the increasing heat of the sun may injure the plants.

The other mode consists in hanging on the inside of the glass a shade of thin linen or cotton material. This plan is easily adopted, but the shade can only be properly managed by raising and lowering it with cords close to the glass, as the ordinary method of doing so by means of rollers would be injurious to many of the plants in the window, or could not be used at all. If this inner shade be raised and lowered by some contrivance similar to that which is employed for the windows of railway carriages we may consider it the best kind of shade, as it can be used or removed at all times, is not affected by the weather, is easily managed, and, lastly, is not expensive.

With reference to shading in general, it is to be particularly observed that it promotes a luxuriant and strong growth of the plants by inducing a moist atmosphere; but if it is carried to too great an extent, it is unfavourable to the production of flowers. Therefore, wherever a permanent shade is employed, it should not be used sooner than the season of the year renders it absolutely necessary, and should be removed early in autumn; at the time when no shade can be given, ventilation both from within and without should be employed according to the weather. But where a movable shade is used, the plants should have the benefit of the morning and evening sun, and should be shaded only from eight or nine o'clock in

the morning until three or four o'clock in the afternoon. In winter, the sun may be allowed full access during the entire day.

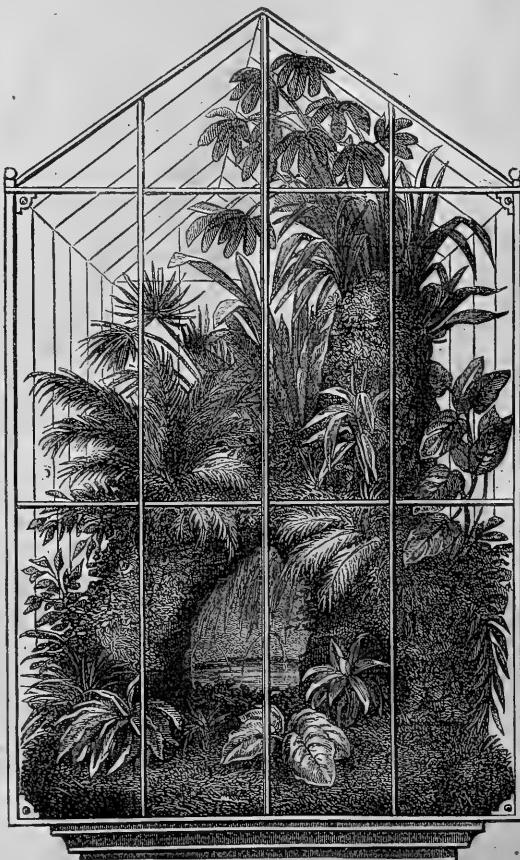

INTERIOR ARRANGEMENTS.

Double windows, which always possess a greater depth than ordinary room windows, should bring safely through the winter as large a number of plants as possible, or supply flowers during the winter months for the other windows or for flower stands. For this purpose, in addition to the lowest shelf, or that which rests immediately on the window-sill, one

or more shelves should be added. In order not to interrupt the circulation of the air, instead of boards, the upper shelves should be made of laths placed at the distance of an inch from each other. These laths should, moreover, be moveable, so that they may be all or partially removed at any time when the growth of the plants below them renders this necessary.

The uppermost of these shelves will occupy the warmest and the driest position, and on that account are the most suited for the forcing of flowers. The plants placed on them are reached by means of a movable ladder with steps on both sides.

Finally, in "in-serted" double-windows, at the bottom of which there is no reservoir for heating purposes, the taller plants are placed on a board which lies on the ground, and only single small plants on the window-sill, which is not more than $1\frac{1}{2}$ foot broad, and immediately in front of the lowest panes. The height of the lowest shelf from the ground depends on the height of the plants, the tops of which should receive as much light as possible. By the arrangement of

Large Plant Case

the plants on separate shelves, the smallest and weakest specimens will be next to the window, and the larger ones placed further back, so that each may have as much light as possible.

Further, the plants in the double window should not be placed so closely together that their branches will touch each other, or even that some of them may lie against others, otherwise only thin bad specimens will be grown, as occurs in plant houses under the same circumstances. We may here repeat what has been already said, that it will afford the cultivator more pleasure and satisfaction to raise a few good specimens than many bad ones.

PLANT CASES.

A contrivance much adopted for the culture of plants in rooms, especially for such plants as do not thrive in the dry air of a room, and which has been frequently employed with the best results, is a large glass case arched at the top; or it may be of small size and constructed of glass and iron, and placed on a table or stand near the window. When it is of small size, the whole of the top may be taken off in order to attend to the plants, and when of large dimensions, windows or openings are made in the sides for the same purpose. The particular form of the case and the table or stand may be varied in a manifold degree.

The figure on p. 359 is an illustration of one of these plant cases of moderate size. The stand bears, firstly, like most flower-stands, a box or case, made to fit it exactly. Inside this case is another made to lift out, and formed of zinc or of tinmed iron, with a pierced bottom, and a tray underneath to receive the water which drains down, and which is carried off through acock underneath. In order to expedite the drainage from the upper case into the tray, the upper case should stand on hollow supports. We have also given a vertical section of this arrangement, on which the permanent thriving of the plants cultivated in the plant case depends, for unless the drainage is perfect, the earth ceases to be percolated by air, and becomes sour and unfit to furnish proper nutriment to the plants.

In the culture of stove plants, this most important point must be attended to, not only in reference to the plant case, but also wherever plants are grown in iron boxes which stand in wooden cases (as, for instance, for forming arbours in windows, &c.), similar precautions must be taken with regard to the drainage.

The iron case is now filled with earth, in which are planted Ferns, Aroids, Marantas, Bromelias, Selaginellas, Palms, &c., or pieces of stone may be placed in it, between which earth is to be filled in and planted with a suitable selection of plants which can be grown between the stones.

In plant cases of larger dimensions, little landscapes with fountains, cascades, and tiny mountains may be represented. Dead branches of trees, of not too great a size, and knotty roots, may be placed here and there; and, planted with Bromelias, Orchids, and Aroids; handsome baskets and other contrivances containing Orchids, *Asplenianthus*, &c., may be suspended at intervals, while dwarf Selaginellas and neat Ferns cover the turf between the plants.

On the preceding page is an illustration of the gable end of one of the largest plant cases that we have seen, and which Herr Gravener Zimmerman has constructed and set up in a room of his dwelling-house in St. Petersburg. It is 9½ feet long, 5½ feet wide; the windows are 5½ feet high, and the height of the gable end is 7½ feet. The stand supports a reservoir of zinc filled with water, the surface of which is for the greater part covered, with the exception of an irregular space in the middle, where numerous fountains play and gold fish swim about, while water drops continually from the cliffs in the foreground. This water passes into the under basin. Where water is not used, the basin is covered over with a perforated plate, on which a layer of soil is placed, and in this many kinds of handsome indoor plants, such as Ferns, Palms, Aroids, Scitaminea, Lilies, &c., are planted, the surface under them being covered with a green carpet of Selaginella, *Ficus*, and *Tradescantia*, while here and there handsome small specimens of variegated Caladiums, *Eranthemums*, and *Glossiamis* in flower add greatly to the effect. Between these plants arise several higher cliffs, of which the one represented in the foreground contains a zinc reservoir at the height of four feet from the bottom, which feeds the fountains and the little cascades which fall from the rocks. The water is forced into this reservoir from the larger one by means of a pump placed under the stand. On the cliffs and in their crevices grow all sorts of ferns, *Dasyliurions*, Aroids, &c., and here and there knotty branches are furnished with climbers, Orchids, Bromelias, and similar plants, which attain a luxuriance equal to that which ones sees in a regular plant house.

We know that the Japanese delight to give a representation of a whole landscape on the smallest scale in their little gardens; but in the plant cases we may have before our eyes,

the whole year through, the luxuriant vegetation of the tropics on a small scale; and, confined to a town life, may cultivate for our enjoyment a pleasing collection of the finest and most tender plants from all countries.

CONSTRUCTION OF A PLANT CASE.

The roof of the plant case may be of various shapes—angular, round, vaulted, &c.—but it should always be made as light as possible. The frame may be of cast iron, wrought iron, or sheet iron, and should be painted and varnished to preserve it from rust. In plant cases of small size the entire glass cover can be taken off, or a large bell-glass may be used; in those of moderate size single panes are used as windows to open and shut. In those of larger size, a cast iron or wrought iron frame is used, covered with lightly constructed iron framed windows, which can be raised at pleasure to put in and take out plants. In Herr Zimmerman's, the framework is made of wrought iron, and all the lower windows open on hinges. A similar structure of wood would be too clumsy, and would, from the effects of the summer air and the moisture inside, soon warp and require to be repaired.

POSITION OF PLANT CASES.

In order to secure good results in the plant case, it should be placed near the window in a position where the sun may shine on it during the greater part of the day. Where the room is not exposed to the sun, the plant case should be placed near the window, and a selection made of such plants as thrive in the shade, such as Ferns, Aroids, &c.

Plant cases of large dimensions, like that of Herr Zimmerman's already described, should be placed at a distance of about three feet from the window, as if placed nearer, the shade of the window piers would be injurious to the plants, and yet the window should be near enough to allow of the beneficial influence of the sun. Where the locality permits, a corner room exposed on both sides to the sun should be selected for plant cases of large size. While small plant cases on stands as high as the window-sill are best placed in the window recess, those of larger size, which must be placed some feet from the window, should be on stands not more than from one foot to one and a half foot high, this being the best height for light, management of the plants, and also for the decoration of the room.

WARMING PLANT CASES.

As the plant case stands in the apartment, special heating is usually unnecessary. Only when variegated tropical plants like *Anactochilus*, *Marantas*, *Caladiums*, &c., are grown in cases of smaller size, or when East Indian orchids, such as *Vandas*, *Saccobiums*, &c., are grown in those of greater dimensions, can heating be employed with advantage. For this purpose, as in the case of the double window, a hot-water apparatus only can be employed, and that may be either such a one as was there described, or a small covered reservoir may be placed underneath, at a few inches distance from the bottom of the plant case, and kept heated by a lamp. To conduct the heat, pipes should be laid under the soil of the plant case and along the surface of the stand. If the reservoir or the pipes are placed in immediate contact with the soil in which the plants grow, so much vapour will be developed from the soil, which will be condensed on the inside of the glass, as to obscure or totally hide the plants from view, and so all the effect of the arrangement will be lost. Finally, wherever large cases are placed in rooms with a temperature of from 60° to 65° Fahr., instead of employing artificial heat, it will be sufficient to water and sprinkle the plants daily with tepid water and to keep closed vessels of hot water near the cases.

ADVANTAGES OF PLANT CASES.

The glass covering of plant cases not only shelters the plants from the effects of dry air, from great changes in the temperature produced by air and heat, and lastly from the hurtful dust, which in all dwelling-rooms covers the plants more or less, but it also prevents an undue exhalation of moisture from the soil and the plants, so that in the inside a moderate, equable, moist, and warm temperature is maintained, which, for a large number of the handsomer tropical plants, is an essential condition of successful culture and strong healthy growth. By the double glass covering the quantity of light

which reaches the plants is somewhat diminished. But as the greater number of plants which love a moisture-laden atmosphere do not naturally grow in localities exposed to the full sun, but rather in the shade of shrubs and forests, such as ferns, the greater number of the monocotyledonous plants of warm countries, and many of the most admired fine foliage plants (Aralias, Rhopalias, &c.) of our hothouses, they will not at all suffer when the case is placed in an otherwise favourable sunny position near the window; if a suitable selection of plants has been made. Thirty years ago bell glasses and water glasses were very much used in rooms, and placed over cuttings to induce them to strike root. The plant case is merely an expansion of this idea, which however, was first practised on a large scale by Dr. Ward, of Clapham Rise, about thirty years ago.

MANAGEMENT OF PLANT CASES.

With respect to special treatment, we add some instructions which, however, are particularly applicable in the case of plants from the warmer latitudes. Every day the plant case should be visited once, and every withered or fallen leaf and shoot should be removed. Moreover, should any mouldy or disagreeable smell be perceived, the cause must be sought for and removed, and all the windows should be opened for some hours, or the glass covering removed, so as to give free access to the fresh air. The windows must always be kept clean, and be regularly wiped inside and outside. Small cases should be washed on the inside once a week. A mouldy smell, foul air, and a diminution of light are the consequences of neglecting to cleanse the cases. Plants in a plant case do not require to be watered so often as those in the open room. In dull weather, and during the short days of winter, care should be observed in this respect, and no more water given than is absolutely necessary. In fine, sunny spring and summer weather, it will be proper to sprinkle and water carefully with tepid water. This will also remove any sourness that may exist at the bottom of the case. As it is chiefly plants from the warm latitudes which should be grown in plant cases (Ferns, Orchids, Marantas, &c.), a watering and sprinkling of tepid water, will prove very beneficial even in winter. When the room windows are opened in mild, warm, dull weather, the windows of the case should be opened, and the bell glasses raised in order to give the plants some air. In dry, hot summer weather, the plants should be slightly sprinkled in the morning and evening, and air should be admitted at night as well, to renew the air in the case as well as to lower the temperature.

When the growth of individual plants is so luxuriant as to interfere with that of other plants, or to produce crowding and choking, they must either be trimmed or removed altogether. If in bright, hot summer weather the case comes under the direct rays of the sun, it should be shaded during mid-day by suspending a curtain in front. If no shade is used, then air must be admitted, and the plants should be sprinkled.

ARRANGEMENTS WITH REGARD TO PLANTING.

When, for purposes of planting, earth is to be placed in the case, the perforated bottom which serves for carrying off the water should first be covered with potsherds, in such a manner that a concave piece may be placed over each of the holes. In this way the bottom will be covered with a layer of potsherds half an inch deep. On these should be placed a layer of clean sphagnum, and on this the soil, the most suitable mixture for which is meadow loam with some loose peat and sand. A stiffer mixture may be used between the stones of the rockwork, consisting of heath soil or turf or well-rotted leaf mould and loam.

In consequence of too strong a growth, deterioration of the soil, and the decay of individual specimens, certain parts, or even the whole, of the plant case must be planted afresh from time to time; in which case, fresh soil must be added under the directions already given. The most suitable time for this operation is in February and the beginning of March, when the new growth commences. The Selaginellas, which form the green turf, must be removed as often as they grow too thick and too long, as this spoils the appearance of the turf. With these (*i.e.*, the kinds generally used for making a turf) there is very little trouble. They are simply pulled up, and in their place fresh roots or growing cuttings are put in in tufts, and

from these new and similar turf will soon be produced. This however, should not be done from the middle of October to the beginning of January.—*From the German of Dr. Regel.*

(To be continued.)

DRAINAGE.

[The following admirable essay was recently read before the Institution of Surveyors by Mr. R. B. Grantham, C.E. It merits the attention of all interested in garden drainage.]

Artificial drainage and outfalls are the leading works in all systems of land drainage, and to them I have paid particular attention as the means by which minor or subterranean drainage can be carried out safely, effectively, and permanently; but, without a knowledge of the requirements of pipe drainage, artificial drainage cannot be properly designed and executed. The end of all pipe drainage, let the depths be what they may, is to keep the subsoil water at such a level as not to allow it to rise to the roots of the plants, and injure their growth by its coldness and non-fertilising properties, and to render the soil above the pipes more friable and open, by making it moderately dry, and causing a circulation of air through it. A very prevalent opinion existed that the sole use of pipe drains was, to take off to an outlet, water which descended upon the surface of the land as rain, or overflowed it from springs, &c.; and with many farmers this idea is still prominent, and they cannot understand that if drains are sunk in clay soils as deep as four feet, the drainage water will ever reach them, or the land ever be improved; and if left to themselves, they would not lay the drains deeper than two feet or two feet six inches. I have many times tried to convince them what is the source of the water, by showing it to them by trial holes dug in stiff clay, and asking them where they thought it came from, as there was no appearance of its having run down the holes from the surface of the land, or of its having percolated from the sides of the holes. I have shown them that it could only rise from the bottom; but in few instances only have I found that the conviction, even if arrived at, lasted very long. I have also shown them that, after a drain has been dug out to its proper depth, in a few hours water will gradually rise where there was none before. Many instances are well known in which shallow draining, say from two feet to two feet six inches, has been taken up and the pipes relaid at depths of four feet and upwards; and it is scarcely possible to believe that in the present day persons can be found who would practise shallow in preference to deep drainings. When the soil between the drains has been rendered perfectly permeable, so that rain-water sinks to the full depth of the drains, and the subsoil water rises up to their level, the work may be deemed to be satisfactory, as showing that the drains have not been placed too far apart, having regard to the depth in the particular soil which is being treated.

SOILS.

In laying out drainage the principal difficulty in determining both the depth and width apart of drains, is found in dealing with the different kinds of soil that are met with. The first questions that naturally arise are—What is the geological formation of the locality? and what is the inclination or dip of the strata? From the answers to these questions we are able to infer the existence or absence of permanent springs. Thus, for example, beds of gravel, sand, or other free soil, surrounded or underlaid by beds of clay or other impervious strata, store up large bodies of water, which, by slow percolation, saturates the surface of the country. So that we can in such cases, by simple means and a small amount of work, free large areas of land from wetness. A knowledge of the soils may be gained by sinking trial holes, exceeding in depth the proposed drainage, or by boring to moderate depths. Soils may be classed in two grand divisions—clays and free soils, and it is these we have to deal with; but it must be remembered that each of them admits of several subdivisions, and in both cases rock may be mixed with them.

DEPTH OF DRAINS.

Four feet minimum depth of pipe drainage has been fixed after mature deliberation; but it ought not to be imperatively insisted upon in every kind of soil or under all the varying conditions of land. One constantly meets with the objection

that water cannot get down through thick clay, and that it is useless to go so deep as four feet; but our experience teaches us that the soil, having become more loosened and opened by cracks, admits the permeation of water to that depth at least; the very worm-holes permit the rain to percolate; and after it has once found its way, by gravity, through the soil, by innumerable small passages, it never ceases, year after year, to continue the same course. Thus, in course of time, the whole depth, from the causes before cited—namely, the prevention of the capillary attraction upwards of ungenial water, the admission of air by the pipes, and the gradual filtering of rain from above—is totally changed in character from that of an obdurate and untractable soil to that of a more genial plant-producing one. The same effects are produced both in arable and-pasture lands; but the system to be adopted in draining them is somewhat different. I have hitherto endeavoured to prove that there is a certain minimum depth at which pipe drainage is capable of producing the best results, more particularly when applied to stiff clay.

DISTANCES APART.

I think a general rule might be established to determine, in connection with the depths, the distances at which the drains should be placed apart from each other, and that is that the width should be a multiple of the depth, for instance, four feet drains may be 16, 20, 24, 28, 32, 36, or 40 feet apart, the depth being first found at which the level of the water bed stands beneath the surface. We must then judge, from the nature of the soil, whether it will allow of the water finding its way, for half of any of the above widths, to the pipes; always bearing in mind that water will find its way most quickly to a vacuum or the point of least resistance. Take again any soil in which it may be found that the water level stands at five feet deep, the multiple may be 40, 45, 50, 55, or 60 feet, and so with six feet drains the widths may be 60, 66, 72, 78, 84, or 90 feet. The drainer's judgment and experience will enable him to determine at which of these widths the particular soil which he finds will act best, remembering again that each line of pipes, i.e., each drain, only influences half the distance between it and the next one on either side of it.

(To be continued.)

THE FLOWER GARDEN.

THE ROSE SECRET.

I HAVE been making all sorts of guesses as to what Mr. Reynolds Hole's secret for the easy propagation of rose trees can be, and wonder if perchance it could possibly be the same method which I have several times used successfully, not only for rose bushes, but for divers other plants; whether it be the same or not, mine can be easily put to the test by anyone who takes an interest in the matter. This method is only a modification of the one long used in France (and in other countries, I dare say) for the propagation of some hard woodied plants, such as the Oleander, and which consists in placing the cutting in a bottle of water hung out in the open sun. I choose the rose cuttings rather stunted and not too luxuriant, and place them in a shaded part of a moderately heated greenhouse, in bottles, jars, or any sort of vessels filled with water, into which I put a piece or two of charcoal to ward off putrefaction. Making roots is a mere question of time, and sooner or later they are sure to appear. I have propagated all sorts of plants in this way, even such as would have been supposed too liable to rot, from being herbaceous or very pithy. I have rooted large branches of Aucuba with stems as big as my finger, notwithstanding the pith, which is considerable in that shrub, and have succeeded perfectly with Verbenas and such like, also with Vines, Heliotropes, Fuchsias, Candytuft, Dianthus, and in general most bedding plants. I have never done this on a large scale, and only for convenience sake, or from curiosity. I once made a border of perennial Candytuft, requiring two or three hundred cuttings, which I placed all in one jar, they rooted very quickly, and were at once placed in rows; another time I broke accidentally the stem of a large bushy Diplacus, in the month of February, and at once took off every branch with the heel on and placed them in a glass jar; they were rooted in fifteen days, and were nice potted plants long before the time for turning out. With respect to Roses, I may perhaps have rooted fifty or sixty cuttings at different times and of all sorts, and do not remember any failures. I generally placed them in water at pruning-time, say from 1st to 15th March, before the leaf-buds

broke; but have also rooted them at midsummer while in full leaf. I have no doubt the method may be systematised, and the evolution of roots hastened to any required degree by means of large pans with hot-water pipes passing through them. The great thing is to keep the water sweet and to obtain the evolution of roots before there are any symptoms of decay; judiciously applied bottom heat and leaving on as many leaves as the cuttings can bear, will, of course, tend to promote this.—FREDK. PALMER, *Versailles*.

— THE following is a method of striking rose cuttings especially adapted for increasing rapidly new and scarce varieties. In November procure from the nursery the kinds you desire to possess. I should have no objection to their being on the Manetti stock, if budded close to the ground. Plants on their own roots can scarcely be obtained strong enough to yield plenty of cuttings; in fact, new roses can hardly be obtained at all on their own roots: When received, shorten back their roots and pot them into six or eight inch pots according to their strength, completely burying the stock if possible. I must say, however, that with most of the plants on Manetti stocks that have come into my hands I have found a difficulty in doing so. When potted, give a good soaking of water, and place them in a cool house. About Christmas prune them, cutting away all weak shoots, and shorten well back all strong ones. In January fill a pit with leaves and stable dung, so as to produce a nice sweet steady bottom heat of 75°. Plunge the pots in the pit, and for the first three weeks give abundance of ventilation, as the object is to induce vigorous root action without unduly exciting top growth. When growth commences, use the syringe freely early in the afternoons of sunny days, shutting up the pit at the same time. Remove every flower bud that appears as soon as observed, and supply them freely with liquid manure. A very suitable liquid manure may be made for this purpose by dissolving 1lb. of guano in a barrel of soft water (thirty-six gallons). When the wood is sufficiently advanced, propagating may be commenced. Some judgment is necessary in selecting the wood of the requisite firmness, as soft growth will damp off; but anyone who has had experience in budding will understand what I mean. As soon as the shoots have reached the proper degree of solidity, commence taking off the cuttings; each joint with a leaf and bud attached will make a cutting. Leave the leaf on entire, and about an inch and a half of the wood below the bud. Remove with one stroke of the knife a thin strip of the outer bark, commencing on the opposite side of the bud and reaching down to the base of the cutting. The object of this is to facilitate the emission of roots. Insert the cuttings round the sides of six-inch pots, with the leaves pointing to the centre; do not use a peg, but take the cuttings between the finger and thumb and gently but firmly press them in. The base of the cuttings thus have a firm resting-place, which is a point of some importance. Plunge the cutting pots into a brisk bottom heat of 80° or 85°; shade on bright, sunny days and keep them close. Do not let the leaves flag, but guard against damp, and in a very short time they will be rooted. In preparing the pots for the cuttings, let them be well drained, placing a few rough pieces of turf over the drainage. Fill the pots to within half an inch of the top, and water them with a rose pot; let them drain for half an hour, then apply about a quarter of an inch of dry, sharp silver sand. When inserting the cuttings, the dry sand will fill all cavities, and a gentle sprinkling with water will make all firm. Weak spindling cuttings seldom make strong plants; therefore it is important that the plants producing the cuttings should be well attended to, and that, as far as possible, every flower bud should be removed, in order to induce strong vigorous growth. In buying roses for this purpose, I should prefer them from the open ground rather than have plants in pots; because the plants from the open ground will generally be the strongest. Where the necessary convenience exists, it is not too late now to give this plan a trial. There is nothing new about it, for I have put in rose cuttings from single buds many years ago with scarcely five per cent. of failures. The great thing is to take the wood when it is beginning to get firm, which is generally about the first week of the blooming period; of course, all the shoots will not be ready at the same time, therefore, if a large stock is wanted, the work of propagation may go on for several weeks. Many hundreds of cuttings may be obtained in this way from only a few strong plants. A very good plan of striking roses when cuttings are plentiful is to put them in a prepared bed under a north wall or fence in October. Make the cuttings about eight inches long, and plant them thickly in rows, in a slanting direction, leaving about two inches of the cutting out of the ground. This involves little trouble, and in a favourable season a large percentage will root. In severe winters a little hay scattered thinly over them will protect them.—E. HOSBURY, *Ramsey Abbey*.

— So Mr. Hole has a "rose secret" which he dare not divulge. Why did he not, like another Church dignitary I have heard of, arrest

the secret in its shell yith, "Stop, stop, I must first call in a few friends to help me to keep it"? Be that as it may, perhaps some of the following guesses may anticipate his solution of the enigma. Rose roots, I find, may be converted into plants in the same way, though not quite with equal certainty, as the roots of Pelargoniums. Cut them into handy lengths, plunge them into a bottom heat of from 70° to 80°, with a fair share of moisture, and white feet will run down, and a white head pop up, like a piece of blown glass; and presently, from these, venerable veritable crown-shoots, like delicate asparagus tops forced in the dark, will spring out, and grow up into roses. There is yet another and a surer method of manufacturing plants from the root stocks of roses. Behead a rose on its own roots down to within an inch or two of its root-crown. If you leave much stem the subsequent procedure will be useless, as the strength of the plant will rush stemwards, as water flows through an open channel. In this case we want to force the water, as it were, uphill; therefore little or no open channel or stem must be left. Plunge this root stock, with the chief roots barely covered, into any light stuff, in the same high temperature as that prescribed for the rough root cuttings. Continue this treatment until a great forest of suckers appear. Then cut the roots into fragments, with a rootlet or two and a single shoot attached to each; return to a genial temperature of 60° or 70° till the plants are established. What may prove a secret to some, is striking roses by means of buds. At first sight, one can but wonder that this has not been more generally done. Reasoning from analogy, it would seem as easy to root a bud in moist sand or earth as in the bark of another plant. But the living sap makes all the difference; and I have never succeeded in rooting a bud of a rose in the earth with only the bark attached, as in common budding. Something more than this is needed; that is found in a portion of the wood. Use rose buds as we mostly do vine buds and scarcely one of them will root. Cut the shoot asunder lengthwise, removing from one half to three quarters of the shoot; make the base smooth; cut the ends clean and square, about half an inch on either side of the bud, and treat them properly afterwards, and many, perhaps all of them, may grow into plants. There is, however, an element of uncertainty about it, depending upon the state of the wood, the period of the season, the variety of rose, and the treatment given. I have found a bottom heat of from 70° to 75° best for this work. The rationale of the treatment is this:—First of all excite the bark to form a callus either at the ends or on the sides of the wood. When this takes place, the bud is safe; but, should the bud grow fast, as it will if placed in the same temperature as its base, it will have expended its store of growing force on its own elongation rather than in making roots. Consequently, as soon as the store of food treasured in the wood and bark are exhausted, the bud perishes; otherwise, it lives. This mode of increase may be adopted at any season when dormant buds are available. It is, however, most successful about the end of June with the first matured buds of the season. The best place for operating in summer is a pit or frame, in which the bottom heat can be regulated, and the surface temperature kept down by a north aspect, shading, sprinkling, &c. The China section is the easiest managed in this way, including, of course, Teas, then Noisettes, Bourbons, Perpetuals, in the order I have placed them. Provence and summer roses are the worst of all to root from buds, and can, of course, only be tried in winter. Records of experience in this matter, such as you have had in your pages, are extremely interesting, and may tend to cheapen roses, or, at least, make them more plentiful.

D. T. FISH.

The Veitch Memorial.—We understand that the trustees of this memorial have invested the balance of the fund, amounting to £870 in stock of the Great Indian Peninsula Railway; and that as soon as sufficient interest accrues to render the prizes to be offered worthy of the object in view, they will proceed to make arrangements to determine their relative value, and to submit them to public competition, in accordance with the powers conferred upon them by the subscribers.

Railways and Public Parks.—Everyone who knows Birmingham is acquainted with a public park or chase in its neighbourhood, like Bagshot or Windsor, of about 3,000 acres, including woods, lakes, and a small portion of cultivated ground. It is called Sutton Park, and forms one of the principal lungs of a district populated by a million of inhabitants. The thousands who have visited this park will learn with dismay that there is a proposal to run a railway across the best portion of it, destroying the picturesque character of the scenery, and cutting off communication between one side and the other. From a sanitary stand-point, the injury, destruction, or enclosure of large parks and open spaces is most lamentable, especially when these happen, like Sutton Park, to be in the neighbourhood of great centres of population.—*Lancet.*

OUR WEEKLY CALENDARS.

This first attempt at garden literature was a calendar of garden operations, and a calendar must ever be an important and a useful feature in a gardening periodical. Hitherto calendars have been, as a rule, invariably written from current observation in one place, aided by compilation from already published records; but in consequence of the many important branches in which the art of gardening now presents itself, it is manifestly impossible that any one man or even half-a-dozen men can from actual observation write such a calendar as will meet the multifarious wants of the now vast gardening public. It has, therefore, occurred to us that we might make a useful innovation in the art of calendar-making, by giving weekly a faithful and comprehensive record of the work actually performed in every kind of garden, during the current week, around that greatest centre of gardening in the world—London. Ordinary weekly or monthly calendars all possess the disadvantage of having to recommend the performance of operations which a sudden change in the season may render impossible or unwise. But, as henceforward our weekly calendars will describe work actually performed, and being carried out, in private and public gardens, nurseries, and market gardens, by the best practitioners in these respective departments, the public will have, on the appearance of our paper, a reliable weekly guide as to the garden operations that require most pressing attention; while our monthly calendars, issued in the first number of each month, and written by some of the ablest gardeners in England, will indicate the general plan of the month's operations. The climate of Britain doubtless varies a good deal; still, a record of garden operations carried on around London, will, for all practical purposes, be a trustworthy guide for all other parts of the country. The short space of time that will elapse between the conclusion of our week's observations and the reception of them by the public, can make no practical difference to readers in the southern parts of England and Ireland, whilst for the large portion of our readers who live considerably north of our great metropolis, the directions will come in good time. We have only to add that daily observations in all the best private, public, and commercial gardens in and around London, will be made by competent reporters in the special interest of this department of THE GARDEN.

GARDENING AROUND LONDON.

PRIVATE GARDENS.

Conservatories, &c.—At present conservatories everywhere are gay with Camellias, Heaths, Azaleas, Acacias, Cytisus, Daphnes, Epacries, Hyacinths, and other bulbs; Cyclamen, Primulas, Mignonette, Cinerarias, Violets, Callas, Bouvardias, and many other things, the whole being intermixed with fine-folaged plants, which serve to set those in flower off to good advantage. The temperature of these structures is now kept at about 45° or 50° at night, allowing a rise of 10° by sun heat. Plants started into growth receive more liberal supplies of water, and the atmosphere is kept moist by sprinklings from the syringe. Flowering plants from the forcing pit take the place of those done flowering. The beds, which have been top-dressed, are kept neat and trim. Air is given plentifully in the morning, shutting up early in the afternoon. Greenhouse plants have now been nearly all repotted. Such as intend to exhibit their plants, are now busy training, accelerating, or retarding them. To Bougainvilles, Clerodendrons, Stephanotus, Caladiums, &c., they give a brisk heat and plenty of moisture. Azaleas, Genettillas, Dracophyllums, Chorozemias, &c., are kept neatly trained, and Pelargoniums are placed on shelves close to the glass. Cinerarias and Calceolarias are shifted into their flowering pots.

Stoves.—The potting of stove plants is in general finished. To such as are in active growth, water is freely given both at root and overhead, and the atmosphere is kept moist by frequent sprinklings on all available surfaces. A little shade, when necessary, prevents scorching. Air is given in the morning, and the house is shut up early. Gesnerias, Gloxinias, Achimenes, Caladiums, are potted and placed in heat to succeed those previously started; Orchids are being repotted, and those most actively in growth receive a good supply of moisture at the root and in the atmosphere; but those starting are only sparingly supplied at the root; the atmosphere is, however, kept warm and moist by frequently sprinkling, with the syringe, the paths, stages, walls, &c. During bright sunshine, a little shade is given. Most Orchid-growers place a piece of cotton wadding round the stems immediately below where the flower spikes appear, to prevent the ascent of woodlice, &c., which eat the points off the flower spikes. Ferns are kept growing steadily, and have all been potted, except some of the hardy sorts that are

kept for conservatory decoration; these latter are now receiving a shift, and being placed in cold frames.

Pits and Frames.—Where there is no propagating-pit, hot dung beds are now devoted to that purpose. Cuttings of Coleus, Alternantheras, Heliotropes, Ageratums, Geraniums, Lobelias, Mesembryanthemums, Tropaeolums, Calceolarias, Verbenas, Gazanias, &c., for bedding purposes, are being constantly put in, and as soon as rooted are potted off singly, and their place supplied with another batch of cuttings of the same. Wigandias, Solanums, Verbascas, Polymnias, and many other sub-tropical plants are placed in heat, when they yield abundance of cuttings, which are easily propagated in the ordinary way. Chrysanthemum cuttings, which are rooted and potted separately, are placed in cold frames, kept close for some time, and gradually inured to light and air. Annuals required for early flowering in conservatories are now being sown in pots in heat. Polemoniums, Phloxes, Sempervivums, and other hardy plants wintered in frames, are being taken out, and set in sheltered places, to make room for other things. Echeverias in boxes are kept under stages, or anywhere in a cool house where they can be kept dry. Lilies in pots, as they appear above ground, are kept near the glass. Stocks in pots are being repotted, and single ones, as soon as discerned, are cast away. Yellow Pyrethrums, Calceolarias, &c., in frames, have the sashes removed during fine days.

Flower Garden and Shrubbery.—Flower gardens, where not previously done, are now being filled with Pansies, Daisies, Forget-me-Nots, Pyrethrums, variegated grasses, Sempervivums, and many other useful spring flowers. Crocuses, Snowdrops, Aconites, Scillas (sibirica), Bulbocodiums, Dog's Tooth, and other violets, Arabis, &c., are now everywhere in full bloom. Flower beds are being neatly trimmed and edged; lawns are being swept, rolled, and mown, and walks gravelled. Grass and ivy verges are being made, and box edgings laid. Pruning of roses in many cases is finished, whilst in others it is only just begun.

Indoor Fruit Department.—Pine apples swelling fruit are allowed an increase of temperature and a moist atmosphere. Succession plants receive plenty of water and heat, and are shifted on as they require more root room. Vine shoots are being stopped and regulated, and bunches too thick are being thinned. For Muscats in flower a high temperature and a dry atmosphere are maintained, but for Hamburgs less heat is needed. Vines breaking are furnished with a moist atmosphere. Early Peaches and Nectarines are thinned, and syringed morning and afternoon, and shut up early. In many cases a little air is left on all night. Strawberries are being introduced into forcing houses, keeping them near the glass; those in flower require a dry atmosphere. Melons and Cucumbers are being sown for a general crop. Those planted out are tied and thinned, and have their flowers picked off until they have strength enough to support fruit. A moist atmosphere is maintained, and water is given freely at the root, avoiding wetting near the neck of the plants. The syringe is frequently used amongst the foliage. Kidney beans are forced in succession, giving them plenty of water at the root and overhead. Tomatoes are being sown. Capsicum sown last month are being potted, and another sowing has been made. Celery is sown in heat, and pricked off as soon as fit to handle, still keeping it in heat. Potatoes in frames are allowed plenty of air; other frames are being filled with tubers, forwarded a little in pots, so as to come on in succession.

Hardy Fruit and Kitchen Department.—Pruning of fruit trees is for the most part finished, and nailing is being pushed forward rapidly. Mulchings of litter are applied to trees that have been lately planted. Grafting has been commenced. Apricots, Peaches, and Nectarines are being protected with nets, thin canvas, &c. Bush fruits have been pruned, and the ground about them dug. Fresh plantations of Strawberries still continue to be made. Artichokes are cleared of litter, and fresh plantations, if required, are being made. Small sowings of Broccoli, Cabbages, Savoys, and Cauliflowers, have been made. A full crop of autumn-sown Cabbages is being planted. Cauliflowers are planted out singly, and also in patches of three, six, or nine, under a hand-glass. A main crop of Onions is being sown, also of Parsnips, Carrots, and Borcole. Leeks are also being sown for transplanting. A small sowing has been made of early Turnips on a warm border. Main crops of Potatoes are being planted. A full crop of Beans, and succession ones of Peas, are being sown. A small sowing of Beetroot has been made, and the main sowing of Parsnips is being put in. Mint, Rue, Savory, Sage, Camomile, Balm, &c., have now their roots divided, or slips detached from the parent plants, and planted in lines. Spinach is being sown between lines of Peas; and of Mustard and Cress small sowings are made on a warm border.

NURSERIES.

Indoor Department.—The most pressing labours under this head are propagating, repotting, training, starting plants that have been at rest, &c. Young Heaths and Azaleas are grown in London nurseries by the thousand. They are now mostly, with the exception of those in flower and specimen plants, kept in cold frames. The potting of Heaths, in most cases, is finished. Camellia blooms are being, in some cases, cut for market; small plants also, with a few nice flowers on them, sell well. Those to be kept another season in the nursery are repotted, pruned into shape, and kept growing on in an intermediate temperature. Young specimens of greenhouse hardened plants in great variety are now being potted off. Those struck in the autumn are placed on the side shelves of the propagating house, there to remain until fit for potting off singly. Cuttings of many kinds are now being inserted in pots under bell-glasses, and set in gentle-bottom heat. Azaleas, Camellias, Daphnes, Roses, Ivies, Citrons, &c., that have been grafted are still kept in close houses, and those that have freely united and are swelling should have their ligatures cut. Cytisus, Acacias, &c., are kept in cool pits or houses. Tropical Palms are mostly all potted, and kept growing in moist, warm houses; the harder kinds, about to be potted, at present enjoy an intermediate temperature. Dracennas have been potted, and are now kept in brisk heat, with a good supply of water. Old and scrappy specimens have been, in some cases, cut down, the stems being used for propagating purposes. Dieffenbachias are also in some instances cut down, and the stems cut into short bits for propagating. Young and shapely plants of them are repotted, and kept in a brisk, moist heat. Gesneras, Gloxinias, Achimenes, and Caladiums, are now started in small pots in strong heat. Marantas have been repotted, and are likewise kept in strong heat. Almost all stove plants have been shifted, and are commencing to grow; they have abundance of water at the root and overhead, and enjoy a high temperature. Orchids are, for the most part, repotted and top-dressed. Aucubas are placed in heat, to induce them to flower freely, and be the more easily "set" by-and-by. In some cases they have been already fertilised. Bedding plants, such as Geraniums, Calceolarias, Alternantheras, Lobelias, Coleus, Verbenas, Tropaeolums, Mesembryanthemums, Heliotropes, Ageratums, Wigandias, Solanums, and many others, are in heat, in order to cause them to yield cuttings more abundantly. Dahlias are started under stages and in any place where they can be conveniently stowed, and where they can enjoy a little heat. Cannas are started in the same way, but are propagated by dividing the roots, preserving a crown to each division, which is placed in a small pot, and kept in heat. Cuttings of Aucubas, Euonymuses, and various kinds of conifers, are now being inserted in silver sand under hand-glasses, and plunged in a gentle bottom heat. Those propagated in the autumn have still the benefit of hand-glasses. Early annuals for conservatory decoration are raised from seed sown now in heat, also bedding plants, such as Lobelias, Centauracs, Petunias, Pyrethrums, Amarantuses, Solanums, &c. Alpine and herbaceous plants in small pots and wintered in frames, are now placed out on beds, on which a layer of coal ashes has been put, and over the more tender kinds hoops are placed, so that in case of frost a mat, or some other covering, may be thrown over them. The pits and frames they occupied are filled with bedded materials, Heaths, Azaleas, Epacries, &c.

Outdoor Department.—The lifting of deciduous trees is now over. The ground where they grew is levelled, dunged, and dug; and the remaining specimens that are scattered over the ground are taken up and re-planted in lines and in proper order. Evergreens continue to be lifted in great quantities for planting, which is now going on busily, although early in September is a better time for such work. Layering of Limes, Acer, Rhododendrons, Laurels, &c., is now being done. The layers are kept in their places by means of small pegs, the point of each shoot projecting twelve inches above ground with its point cut off. Those layered last year, where well rooted, are lifted and planted in lines about twelve inches apart. All open spaces between lines of young trees and shrubs are dug over, and the walks trimmed and gravelled. Climbers in pots are still kept plunged in sheltered places in coco-nut fibre, or some other material, and securely staked. Young conifers in pots are placed on wall borders and plunged. Various bulbs and other plants are turned out of their pots and planted in beds. Grafting has in some cases commenced, and in most instances it is to begin in earnest next week, stone fruits being the first to be operated on. The stock of young fruit remaining after the winter's sales are now being trained, some for walls, pyramids, espaliers, &c.

MARKET GARDENS.

The fine warm weather which we are now experiencing advances vegetation so rapidly that spring work in this department is coming on with a rush. Everybody is now busily employed with Asparagus

beds, which are being covered over with soil dug from the alleys between them, neatly rounding their surface. Lettuces in frames are fully exposed during fine weather, and young plants are being put out between lines of Gooseberry bushes, in open spaces, and on every available surface where deeper rooting and stronger growing things would not answer. Radishes from the earlier sowings are now fit for use, and others are coming on to take their place. Some are little more than above ground, while others are only just sown; therefore in that way a constant succession is secured. Radish-beds are covered with litter until the young plants appear above ground, after which the litter is moved into the alleys, to be replaced on the beds in severe weather. A boy is kept to frighten off birds, which prove injurious to Radishes on their first appearance. Cauliflowers that have been wintered in frames are being planted out, nine under a handglass, which is removed after the plants have got established a little, and only used afterwards for protection from cold winds or frost. From this position they are lifted and planted out, as ground becomes ready for their reception, three being left under each light. Young plantations of Jerusalem Artichokes, where not finished, are now being made. Between lines of young transplanted Onions, Lettuces, Cabbages, and other crops, the surface is being carefully loosened with short hoes. Onions, Cauliflowers, Savoys, Brussels Sprouts, Carrots, Turnips, &c., are now being sown; but seeds for main crops of these will not be put in yet for another fortnight. Wherever ground has been cleared of crops, it is well manured and dug over for something else; in cases where the grounds are extensive, instead of digging the plough is introduced; after which the ground is harrowed, lined off, and planted. Potatoes are now being planted extensively. A good method of economising space is to plant Cabbages (Fulham) about fifteen inches apart in autumn, and to dibble in now some early Potatoes between the lines of Cabbages, which are removed on the appearance above ground of the Potatoes. Successive sowings of Peas have been made, and as soon as they get about an inch above ground they are staked. Rhubarb plants that were forced early have their crowns now fully exposed in many cases, whilst others are still covered with litter, under which the leaves are coming up good, clear, and crisp; open air crops of Rhubarb are also pushing up. Asparagus is forced in frames by lifting the roots, and placing them on beds of fermenting material, covering with several inches of mould; litter is placed over the sashes, and removed for a short time about midday, when a little air is given. Seakale is likewise forced from lifted roots, packed closely in hotbeds, and also in the open ground, in the ordinary old-fashioned way. Young Carrots in frames get plenty of air throughout the day, and are kept growing on steadily. Pruning of bush and orchard fruits is in most cases finished, and the prunings are being collected into heaps and buried. Cleaning the ground is being proceeded with vigorously. From about the stems and roots of bushes and trees the weeds are removed into the open space between them, and there dug into the ground. Beds are in course of formation for the reception of Wallflower seed, this old favourite flower being grown to a vast extent in the market gardens round London.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

The third meeting of the season took place at South Kensington on Wednesday last, under very propitious circumstances as regards weather, but the display of plants was scarcely up to our expectations. Amongst Orchids, however, was a magnificently-bloomed plant of *Phalaenopsis Schilleriana*, which was deservedly recommended to the council for a Lindley medal. It had two great branching flower spikes, on which were no fewer than 207 blossoms in the greatest possible perfection, notwithstanding their journey all the way from the north of Scotland. Other Orchids consisted of well-flowered plants of *Dendrobium Farmeri crassidoma*, and *cambridgeanum*. Some *Odontoglossums* were also shown, but not in such fine condition as at last meeting. Amongst them were some good plants of *O. Alexandrae* and *triumphans*. A few *Lycastes* were likewise contributed, as well as *Oscillidium*, *Vanda*, and *Cypripediums*, together with a good plant of *Cymbidium eburneum*. Of *Camelias* no well-grown specimens were exhibited; but there were some prettily-flowered small plants. Roses, both in pots and in a cut state, were plentiful and good. Of Lily of the Valley, two baskets were exhibited in splendid condition. There were also good collections of Cyclamen and Chinese Primulas, as well as an interesting exhibition of hardy spring flowers, consisting, among others, of a double white variety of common Primrose, the charming Iris reticulata, Dog's Tooth Violets, and Squills. *Toxicophora Thunbergii*, a new plant from Natal, was exhibited; it has close heads of white flowers, which are sweet scented. It promises to be a good addition to our stock of winter-blooming stove or intermediate house plants. Among other things, we noticed the pretty little *Stenagnastra concinna*, and a variety of *Imantophyllum miniatum* called Cooperi, better coloured and larger in the truss than the ordinary

species. A few very nice Palms were shown, amongst which we noticed the handsome *Calamus vesticularis*.

First-class certificates were awarded to the following:—*Calamus vesticularis*, from Messrs. Rollinson, Tooting; *Imantophyllum miniatum*, var. Cooperi, from Mr. Green, gardener to W. Wilson Saunders, Esq.; *Toxicophora Thunbergii*, from Mr. B. S. Williams, Holloway; and *Waltham White Chinese Primula*, from Mr. W. Paul, nurseryman, Waltham Cross.

Among fruit were some good late grapes, prominent among which were *Alicanté*, *Lady Downe's Seedling*, *Barbarossa*, and *White Tokay*. Among other fruits were two good examples of smooth-leaved *Cayenne Pines*, weighing respectively six and a half and five pounds; a dish of very fine Keens' Seedling Strawberries; and a dish of Cox's Orange Pippin Apples, in excellent condition and good in flavour. There were also some creditable dishes of *Asparagus*, *Rhubarb*, and *Seakale*. Heads of Snow's *White Broccoli*, and Myatt's *Cape Broccoli*, were shown by Mr. Gilbert, Burghley Park.

LAW.

CARTER & CO. v. SUTTON & SONS.

On Thursday, before the Master of the Rolls, an injunction was sought by the plaintiffs, Messrs. Carter & Co., of High Holborn, to restrain the defendants, Messrs. Sutton & Sons, of Reading, from publishing certain trade marks, which the plaintiffs alleged were piracies.

It appeared that an advertisement had been inserted by Messrs. Sutton & Sons in January 1872 in one of the gardening periodicals, in which the medal granted by the Commissioners of the International Exhibition was used as a trade mark. Messrs. Carter, claiming this as their exclusive property, communicated with the defendants, and received from them a reply expressing regret that through inadvertence this should have appeared, and at the same time reminding them that in the year 1862 there were two international exhibitions held, viz., the "International Exhibition," and that it was the medal of the latter, and not the former, that the defendants had claimed. The plaintiffs further stated that the same infringement was committed in a work entitled "Sutton's Amateurs' Guide and Spring Catalogue for 1872," and they therefore prayed the court to restrain defendants from issuing such publication, and also to compel them to recall such as had already been issued.

On behalf of the defendants it was contended that a sufficient explanation had been offered, and that in addition the defendants had caused a notice to be inserted in the different horticultural journals, to the effect that a mistake in the medals had occurred, and that the medal of the International Exhibition was not theirs (the defendants). The Master of the Rolls, in delivering judgment, said that the plaintiffs had utterly failed to make out their case; that the injunction must therefore be refused, and that costs would be costs in the cause.

ANSWERS TO CORRESPONDENTS.

W. ELLIOT (Many thanks. *Mandragora officinalis*).—S. R. (The dwarf yellow wall-flower-like plant is *Erysimum ochro leucum*).—J. K. (The Pines you allude to are imported from the Azores: they are fine fruit (and in good condition).)—G. S. (Yes; we shall be glad to have an account of the way by which you get such fine Petunias. Will you at the same time kindly furnish us with your address, not for publication?)—W. DUNSON (7s. Blackwood, we believe).—A SUBSCRIBER, (*Bignonia Cherecera*, *Plumbago capensis*, and *Tacsonia van Volxemi*) are the three best climbers for the conservatory in autumn).—L. SHAW, (*Clematis Jackmani* and *montana*.)

COVENT GARDEN MARKET.—March 9th.

Flowers.—Bonquets consist of white *Camellias* and *Tea Roses* in the centre, surrounded by other flowers and ferns. *Polyanthuses* and the pretty *Primula denticulata* are now making their appearance; among other things we noticed sprays of various Orchids, *Hyacinths*, and other Dutch bulbs, *Violets*, *Geraniums*, *Heaths*, *Mignonette*, *Ilecas*, *Daises*, *Arabis*, *Aubrietias*, and other early out-door flowering plants.

Prices of Fruit.—Apples, Dessert, 2s. to 4s. per dozen.—Cobs, per 100lbs., 6d., to 6s.—Filberts, per lb., 8s. to 10s.—Grapes, per lb., 10s. to 18s.—Lemons, per 100, 7s. to 10s.—Oranges, per 100, 6s. to 10s.—Pears, per dozen, 3s. to 8s.—Pine-apples, per lb., 6s. to 10s.

Prices of Vegetables.—Artichokes, green, each, 6d. to 8d.—Asparagus, per 100 lbs., 8s. to 10s.—Beet, per dozen, 1s. to 2s.—Broccoli, purple, per bundle, 10d. to 1s. 3d.—Brussels Sprouts, per half sieve, 2s. 6d. to 3s. 6d.—Cabbages, per dozen, 10d. to 1s. 3d.—Carrots, per bunch, 5d. to 7d.—Cauliflowers, per dozen, 2s. to 6s.—Celery, per bundle, 1s. to 2s.—Chiles, per 100, 1s. 6d. to 2s.—Cucumbers, each, 1s. 6d. to 3s.—French Beans, new, per 100, 3s. to 4s.—Herbs, per bunch, 2d. to 4d.—Horse Radish, per bunch, 3s. to 5s.—Leeks, per bunch, 2d. to 4d.—Lettuces (French), Cabbage, per dozen, 1s. to 2s., Cos, per dozen, 3s. to 5s.—Mushrooms, per pot, 1s. to 2s.—Onions, per bunch, 4d. to 6d.—Peas (green Continental), 2s. per packet, or 10s. per quart.—Parsley, per bunch, 2d. to 4d.—Radishes, per bunch, 1d. to 6d.—Rhubarb, per bundle, 6d. to 1s. 6d.—Salsify, per bundle, 1s. to 1s. 6d.—Scorzonera, per bundle, 9d. to 1s. 3d.—Seakale, per punnet, 1s. to 2s.—Shallots, per lb., 8d.—Spinach, per bushel, 3s. to 4s.—Tomatoes, per small punnet, 8s.

GARDEN

"This is an art
Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—Shakespeare.

THE INDOOR GARDEN.

FLYING FLOWERS.

BY NOEL HUMPHREYS.

If, as a supplement to the beautiful flowers which the protection of glass enables us to enjoy, we could command the presence of objects of equal beauty, endowed with the additional charm both of life and motion, it cannot be denied that the pleasure derivable from our greenhouses and conservatories would be greatly enhanced. A beautiful butterfly is but a winged flower; the essences of a plant have been extracted for its formation; the fibre of the leaves has probably gone to form the neurations of the broad, sail-like wings; and the rest of the leafy structure to weave the delicate and nature-painted tissue. When the store of delicate material has been collected by the greedy industry of the untiring caterpillar, and duly eliminated from the grosser matter, the continuous accumulation ceases, and the embryo bud of the flying flower is rapidly formed and protectively enclosed in its horny calyx, in which the development is completed; and when the final expansion takes place, the horny calyx is burst, and flung off, like that of a great scarlet poppy; four living petal-wings, like the closely folded petals of the poppy, spreading themselves rapidly out to their full size, essay their strength by a few trial flappings, like the first essays of a young bird, and the flying flower either darts fearlessly through the air in wild and joyous evolution or hovers lovingly above some poor wingless, but yet beautiful, flower that is destined, from the recesses of its luscious nectary, to furnish the delicate food of the newborn butterfly, who seeks it in the depth of its cell with his uncurled, hair-like tongue.

The butterfly's resemblance to a flower is not confined to the beautiful petal-like wings, but the body seems to represent the pistil, and the elegant antennae the filaments and anthers. The analogy seems, indeed, something more than a fanciful resemblance. Chrysalis of the Great Swallow-Tail, the largest of our native butterflies, might be laid on the soil, or on the large leaves of some of the conservatory plants, there to await the period of their expansion. Nothing can be more interesting than to watch the escape of the butterfly from its chrysaline prison, after the first cracking of the horny shell along the back, to the gradual breaking forth of the beautiful insect. When it first drags itself gradually out of its cell, the wings, which are soon destined to assume such large dimensions, in proportion to the size of the body, are little more than mere rudiments, scarcely half-an-inch long; but rapidly, either by the developing of invisible foldings, or by actual growth, they assume their natural size, the almost sudden expansion, or growth, being plainly observable in their rapid progress by the naked eye.

Very beautiful is the aspect of many of our native butterflies. The colouring of the Great Swallow-Tail (*Papilio Machaon*) is bright and striking in a high degree, the light gleaming yellow forming the ground colour being enriched with bold markings of velvet black, rendered gorgeous towards the edges of the hind-wings by splendid pencillings of violet and orange. The charming effect of half-a-dozen or a dozen of these beautiful insects flitting from plant to plant can be readily imagined. It is as though a race of winged flowers had sprung into existence, or as though the petals of certain of the ordinary flowers had suddenly been changed into wings, and gifted with the powers of flight.

In order to secure such a display, it is only necessary to proceed at once to the natural history dépôt in Holborn, or the one in New Oxford Street, and purchase, at the small cost of fourpence each, a dozen chrysalids of *Papilio Machaon*, and place them in convenient places about the greenhouse or conservatory. This is the season at which these chrysalids are to be procured; and to those who have not tried the experiment, the result will undoubtedly prove highly interesting. The chrysalids of *P. Podalirius* can sometimes be procured at the same time, and, possibly, those also of *Parnassius Apollo*, that noble butterfly which may be seen by Swiss tourists on the lower slopes of the Alps. The semi-transparent wings of this beautiful insect are of a light cream colour, boldly marked with black chequers, and also with rich crimson rings, which never fail to attract the attention even of those who are the least susceptible of being aroused to the admiration of natural objects.

If a tank, especially one of natural form, with a sand or gravel bottom, be introduced into the conservatory, as is now frequently the case, the cultivation of a few water insects might add very considerably to the interest afforded by the water plants. A few of the curious larvae of the dragon-fly tribe, for instance, might be collected from neighbouring brooks, and transferred to the conservatory tank; thus affording the opportunity of witnessing the spectacle of their marvellous transformation, from the black and somewhat hideous form of a kind of miniature water demon, crawling about the sand or gravel-bed of the brook or tank, to a creature, whose elegantly formed and gorgeously coloured body is wafted through the air by gossamer wings, whose lace-like neurations are of truly marvellous beauty. When the "creeping thing" at the bottom of the tank has attained to the limit of its existence in that form, it will ascend to the surface, and creeping up the stem of some aquatic plant, will secure itself to that support by means of a loop of silken web, and then sink into the trance (of some few weeks' duration) which precedes the metamorphosis it is about to undergo. The manner of its extrication from the indurated husk of its former shape is extremely curious, and, to those who have not seen it, would form an episode among the more ordinary events of the conservatory, as interesting as that of the first blooming of a newly introduced exotic plant.

In the tropical house there is no reason why the gorgeous butterflies of Brazil and of the Eastern Archipelago should not be introduced. Many of them are far more splendid than any flowers, and adding, as they would, the charm of motion to the splendour of their dazzling metallic hues, they could not fail to form a new feature of a very attractive character. With the present facilities of international communication it would not be difficult to secure the collection of chrysalids by the natives, who possess extraordinary instincts for seeking and capturing the wild denizens of their swamps and forests—from beautiful and harmless insects up to the savage panther and dangerous python. They have, indeed, made a regular trade of it, and it is by their ingenuity, and their knowledge of the habits of the wild animals of their country, that our museums and zoological gardens, both private and public, are supplied. With the command of such a source of supply it ought not to be difficult to obtain chrysalids of the resplendent and dazzling *Morpho Adonis*, of several of the gorgeous *Theclas*, and of many other lovely insects, to form the flying flowers of our hot-houses, and tropical palm houses.

CLIMBING SPECIES OF ASPARAGUS.

The use of these for the ornamentation of rafters and trellises in cool conservatories is not by any means general. They are, nevertheless, plants of easy cultivation, possess elegant foliage, and are useful for bouquets, and when grown in small pots and trained on wire, they make graceful arches for table decoration. They are increased by division of the roots, an operation which should be performed when they are at rest. All the species of this genus are fond of strong soil; and, being natives of South Africa, they grow during winter, when they are most useful, though some are evergreen. Those best adapted for indoor decoration are,—

ASPARAGUS FALCATUS.—This grows from eight feet to ten feet in height; foliage, very fine, arranged in threes, giving the spray a

very elegant appearance when hanging from a rafter. The flowers are white, and very small. Plant, herbaceous.

A. SCANDENS.—A slender plant, with foliage resembling that of our common Asparagus; stem, flexible, from six feet to eight feet in length, giving the plant a graceful appearance, especially useful for table decoration. Herbaceous.

A. DECUMBENS.—A dwarf plant, also with foliage like that of the common Asparagus. It grows in winter, and may be used for hanging over the side of a vase, a purpose for which it is extremely useful.

A. RETROFRUCTUS.—A very strong-growing species, with evergreen stems; foliage, falcate; stem, spinose, attaining a height of from twenty feet to thirty feet. Useful for the ornamentation of a high conservatory, where quick growth is required and large foliage is objectionable. It produces new stems every season, when the old ones, if not required, may be cut away, or, if required to furnish at the bottom at any particular point, they may be stopped back.

J. CROUCHER.

DAMPIER'S GLORY PEA.

(*CILANTHUS DAMPIERI*).

Or the many brilliant greenhouse plants which we have from New Holland, this is one of the most striking. It was discovered in 1699 growing on the dry, sandy islands of Dampier's Archipelago. It is a somewhat difficult plant to cultivate, and sometimes fails even under skilful treatment; yet it may frequently be grown very satisfactorily in our greenhouses or conservatories. The secret of success lies in wintering it properly, as it is liable to damp off. Good plants of it may be obtained in one season, during the latter end of which they will produce flowers in sufficient abundance to amply repay any care that may have been bestowed on them. They should not be wintered in too high a temperature, or watered too freely, especially about the neck of the plants; and in repotting care must be taken not to injure the roots. The seed may be sown either in spring or autumn, but autumn is perhaps the best time. Prepare clean three-inch pots; half fill them with crocks; and fill up with a compost of one half good loam, to which is added another half consisting of fibry peat, leaf-mould, charcoal, and silver sand in equal proportions. Insert one seed in the centre of each pot, and place the pots on a dry, airy shelf of a greenhouse or pit. When the plants have grown about two inches, they should be shifted into pots two sizes larger than those they occupy; replace them on the shelves, and avoid keeping them too damp during the winter. In potting, keep the soil a little higher in the centre of the pots than at their sides, in order to preserve the necks of the plants from being kept so damp as they otherwise would be; and when water is applied it should be poured carefully into the pots, avoiding touching the surface in the centre. Towards the end of February, or as soon as they begin to grow, shift again into two-sizes larger pots, carefully preserving the ball complete, and also the drainage crocks, as their removal would cause the destruction of some of the rootlets, which would prove almost fatal to the plants. I know of no plant so impatient as regards mutilated roots as this. About the end of April they may be again shifted, observing the same precautions; or, instead of potting, they may be planted in a border of well-prepared soil in a pit or greenhouse, where they thrive much better, and there is a greater chance of their wintering successfully; besides they grow more freely, produce their splendid trusses of deep scarlet and purple-black flowers in greater abundance and of finer quality than by growing them in pots, as their roots have more room for free and undisturbed action. The compost used throughout may be the same as that used at first, but rougher.

R. Brunström, a Swedish gentleman, some months since informed me that he has seen the *Cilanthus Dampieri*, when grafted on *C. puniceus*, do much better, and prove harder than when grown upon its own roots; but, as I never remember seeing it thus treated, I should like some information on the subject from some of your correspondents.

In France and the warmer parts of the south of England this plant may be grown very satisfactorily, and made to flower freely in the open air in summer and autumn, by treating it as a greenhouse annual. For this purpose sow in a gentle heat in February, and keep regularly potted before the roots get interlaced with each other. Gradually harden them off,

and, for a short time previous to finally planting them out, they should be left without any protection further than from strong winds, frost, and heavy rains. In the first or second week of June plant them out in a sheltered, sunny, and isolated position in a peaty soil, observing that no stagnant water can lodge about their roots. When thus treated, they form very striking and beautiful objects.

A correspondent of the *Field* describes them, as "flowering vigorously on the sandy soil of New Jersey treated as an annual plant." Mr. Webster, of Gordon Castle, in the north of Scotland, also bears testimony to having grown them outside with good results (and this I know to be true, as I saw them there myself); he thus alludes to them:—"Sow the seed early in March, and nurse them in heat until the beginning of June, and then partially harden by a fortnight's exposure in a cold frame preparatory to turning them out in the open air about the middle of the month. To guard against failure, they are protected for at least a fortnight or three weeks afterwards, by placing over them an inverted flower-pot during cold nights and bright sunshine. The plants treated in the way here described, far surpass in beauty those cultivated in pots and kept under glass. As an illustration of their hardiness, I may mention that we have some plants in fine flower (November 10th), having withstood, unscathed, three degrees of frost, while dahlias, and many of the old sorts of annuals usually cultivated in our gardens, were completely destroyed."

W. F.

PALMS FOR THE GARDEN.

(Continued from p. 313.)

DESMONDS MAJOR (MEXICO).—Plant, erect; stem, one inch thick; fronds, pinnate, three feet long, growing in a distichous manner; leaflets, four inches by one and a half inches; leafstalk and stem clothed with long black spines. Not very ornamental as a general decorative plant; but, owing to its being narrow and flat, it may be used to train up in a dark corner, where other plants will not grow. All the species of this genus get unsightly when old.

D. MINOR (WEST INDIES).—Fronds, eighteen inches; pinnae, two inches, dark green; spines, small. A useful plant when young for side-table decoration.

D. MEXICANUS.—Fronds, five to six feet; pinnae, diminishing in size until at the point they are merely recurved spines, which have a way of catching everything with which they come in contact. Not a good ornamental plant.

DICENIA NOBILIS (SEYCHELLES).—Fronds, pinnate; pinnae, two inches broad, regular, of a purple tint. A metallic-looking plant, with the habit of an Areca; rather heavy looking, and fond of heat and moisture.

EUTERPE EDULIS (SYN., *OEOEDOXIA SANCHONA*: BRAZIL).—Stem, slender when young; fronds, two to four feet, recurved; pinnae, regular, one foot long, channelled on the underside, bright green, unarmed. A graceful plant, bearing a head of elegant foliage, which is supported, when about four years old, upon a slender stem, from two to three feet high. Suitable for table, as well as for general purposes.

E. FISPERA (BRAZIL).—Fronds, five feet long, recurved; pinnae, dense, underside, white; base of leaf-stalk, fibrous. Very elegant, slow growth, and having fronds peculiarly regular. One of the best of all palms for the centre of a warm conservatory.

E. SYLVESTRIS (BRAZIL).—For all purposes like edulis.

GAUSSIA PRINCIPES (SOUTH AMERICA).—Habit of an Areca; fronds, flat, and spreading smooth; petiole, round, bright green. Rather a stiff plant, and a bad grower.

GEONOMA.—A genus of dwarf palms, which inhabit the dense forests of tropical America, where they take the place of underwood, and form dense bushes. All of them are fond of heat and moisture, and they dislike bright sunshine, which is apt to scorch them. They require a moderate bottom heat, and in repotting, care must be taken not to disturb them at the roots.

G. ARUNDINACEA (BRAZIL).—Fronds, entire, one foot long, having a termination like the tail of a fish; stem, slender; height, from three to four feet. Shoots push up from the base, rendering it a tolerably nice plant for the front of a stove.

G. BINERVIS (BRAZIL).—Fronds, pinnate; pinnae, near the point broadest; drooping stem, single. A lax plant, unsuitable for decorative purposes.

G. CONGESTA (BRAZIL).—Fronds, entire. Larger than the last, which it resembles in habit.

G. GIGASBREGITIANA (CENTRAL AMERICA).—Plant, stemless; fronds, four to six feet, irregularly pinnate; pinnae, one to six inches broad.

A fine plant for stove ornamentation, having noble spreading fronds, but too dense to be used for table decoration.

G. MACROSTACHYS (BANKS OF AMAZON).—Fronds, spreading; six to seven pinnæ, three to four inches broad; stem, slender. A nice plant, but apt to get naked, and to push shoots from the base.

G. MARTIANA (BRAZIL).—Fronds, entire, eighteen inches long, ten inches broad; point, bifid, stemless. A grand plant for mixing with ferns and fine leaved plants, adding dignity to its associates.

G. PANICULIGERA (BRAZIL).—Fronds, from four to five feet, pinnate; lax and irregular.

G. PUMILA (NEW GRANADA).—Habit, like that of Ghiesbreghtiana; pinnæ, small. A very good plant for the front of a hot bed.

G. SARAPIGUAYENSIS.—Fronds, entire, of a brown shade, slightly arched, eighteen inches long; bifid at point.

G. SCHOTIANA (SYN., REGALIS, IMPERIALIS, and VERSCHAFFELTII): BRAZIL.—Fronds, from two to four feet long, and in number from ten to twenty, drooping, slender; pinnæ, alternate, one inch apart, same in width. A truly elegant palm for the decoration of either table or house—for both purposes, indeed, not to be surpassed. The petiole being slender gives the plant a light feathery appearance.

G. SEEMANNII.—A fine plant, very like Martiana.

GUILIELMIA SPECIOSA (SYN., BACTRIS: BRAZIL. THE PEACH PALM).—Fronds, erect; pinnæ, regular, with small spines on the veins, and sharp black spines on the stem and petiole. An elegant plant, but not one of the finest of growers; fond of heat and moisture.

HYPOPHORE AMARICALUS (SYN., ZAMEOIDES and ARECA SPECIOSA: MAURITIUS).—Fronds, dense, erect, top reflexed; pinnæ, regular, two inches broad, flat; petiole, stout, base forming triangle; stem, very thick, giving it a swollen appearance. In general habit this resembles an Areca, but is denser; the whole plant has a copper-green tint. It is one of the noblest Palms in cultivation, and when about six feet in height very useful for a central position. It has strong roots, and on that account requires a large pot.

H. VERSCHAFFELTII (MACRATIA).—Habit similar to that last-named, but slighter in all respects, with yellowish stripe in centre of petiole. A very elegant Palm, either for table decoration or for general purposes.

J. CROUCHER.

(To be continued.)

ZONAL PELARGONIUMS INDOORS.

I NOTICED in a recent number of THE GARDEN that Mr. Pearson advocates the cultivation of Zonal Pelargoniums for winter blooming. Will he kindly name a few varieties suitable for that purpose? I have upwards of fifty sorts at present, and have been unable to obtain good blooms at Christmas from more than three or four of them. The following keep my greenhouse gay from spring until autumn, but I am short of a few good sorts on which I could depend for winter blooms. My summer sorts are:—

Douglas Pearson.—A splendid variety; habit good, truss very fine dark crimson.

Lawrence Heywood.—This variety attracts attention before any other, on account of its novel colour and free blooming. It is a free grower, good in habit; colour, pinky magenta.

Othello.—Fine truss of deep crimson, good habit, and vigorous.

Duke of Devonshire.—A fine variety, with trusses of a splendid crimson colour, five inches across.

Wm. Thomson.—Fine truss and habit; colour crimson.

Thomas Speed.—Plum colour, extra fine truss. I saw it at Chatsworth, where they think highly of it on account of its being such an excellent bedder. It is a fine variety, either for indoor culture or for bedding.

Milton is another splendid variety; colour dark red, fine truss and habit.

Mrs. Mallow.—Good truss of dark crimson colour, fine for cutting for large bouquets.

Bayard.—A first-class bedding variety, but no one will hesitate to grow it for the conservatory after seeing what it is capable of doing under glass.

Rev. John Woolley, Alfred (Pearson's), and E. J. Lowe.—All first-class varieties; the first bright crimson, the others rose-coloured; fine trusses of bloom, with excellent individual flowers.

Arthur Pearson.—Has fine trusses of magenta, is a good bloomer, and has a fine habit. I have seen it at Chatsworth.

Wm. Hill.—A splendid scarlet, and most dazzling; the petals overlap finely, but before the truss is half expanded they begin to fall, and I have never yet had an expanded truss of this kind. None of the other varieties do this, the first flowers holding until the truss is fully expanded before beginning to fall. I do not, therefore, recommend Wm. Hill for this reason.

If Mr. Pearson would only send out a white or blush variety, with a truss of bloom something like Lawrence Heywood or Duke of Devonshire, as good in growth and habit, and blooming as freely, the foregoing collection (for blooming from spring to autumn) would be complete.

THOS. LEVER, Denton, near Manchester.

SAND AN UNSUSPECTED PLANT-KILLER.

IF Mr. Fish has such difficulties in procuring good sand (see p. 311), I should advise him to adopt my plan, which is to use none. All plants that like loamy soil are certainly better without any addition to the sand the loam may naturally contain; and, generally speaking, the best loam contains the least amount of sand. Mr. Fish admits that sand is chiefly used for mechanical reasons. Why, then, impoverish the soil with it, when similar mechanical results could be obtained in so many ways less objectionable? For some years past I have never mixed sand with loamy soil, and my plants have never refused to grow on that account; on the contrary, they grow faster, and the soil is not so quickly exhausted. There are many ways of spoiling good soil, and not the least of these is by mixing with it unnecessary ingredients. A soil naturally suited to a plant will last twice as long as the best of composts, and if a compost must be used, the simpler it is the better. For plants that like loamy soil—and seven-eights of the plants we grow belong to this class—if the only loam obtainable is too heavy, a little charcoal or charred soil mixed with it is very often all that is needed; if it is too light, a little clay, dried and pounded, will make it heavy enough; if it is both light and close (from the absence of fibre), both clay and charcoal may be sometimes added with advantage. With these three ingredients, a soil may be prepared mechanically suited for growing any plant that likes loam. Of stimulants I will say nothing here, except that less stimulants would be required if such substances as sand, mortar, coal ashes, and similar applications were kept out of the way, and the soil not put together so loosely that a few waterings wash out all its better qualities. It is surprising what may be done with common garden soil if sweetened with a little charred rubbish. No addition of sand to the natural soil is even necessary for striking cuttings of ordinary bedding plants; while for Azaleas, Ferns, Camellias, and many, probably most, others, it may also be dispensed with.

WM. TAYLOR, Longleat.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Potting Agaves.—When visiting Mr. Peacock's unique collection of these plants the other day we could not help expressing some concern for the person who had to pot them. They are so various and terribly armed that one would think a collection of them might be useful for affording hints in a bayonet or sword factory. When some of the many-leaved species form rosettes close to the ground, it becomes a puzzle to get at the plant, as the leaves are not such as may be bent about without injury. Mr. Croucher, however, gets over the potting difficulty easily. Whenever a species requires potting, it is not disrooted in the ordinary way, but cut right off at the collar. It is then placed on the top of a pot of well-prepared soil; and so quickly does it root into this, that Mr. Croucher assured us he had seen the roots issuing through the bottom of the pot six weeks from the time of decapitation and potting. The plan is as simple as it is excellent.

A Deadly Plant.—A few years ago there was in the Royal Botanic Gardens at Kew a specimen of probably the most poisonous plant ever introduced into England. It was the Jatropha urens, the properties of which are so noxious, that its possession is positively dangerous. The ex-curator of the gardens was one day reaching over it, when its fine bristly stings touched his wrist. The first sensation which he felt was a numbness and swelling of the lips; the action of the poison was on the heart, circulation was stopped, and he soon fell unconscious, the last thing he remembered being cries of "run for the doctor." Either the doctor was skilful, or the dose of poison injected not quite, though nearly enough; but afterwards the young gardener, in whose house the plant was placed, got it thrust into a corner, and would not come within arm's length of it. He watered the offender with a pot having an extremely long spout. In a short time, however, the plant disappeared altogether, and another specimen of the genus Jatropha, which was afterwards introduced, vanished in the like mysterious manner. It was presumed that the attendants were secretly determined that such plants should not be retained in the houses, to cause the possibility of an accident such as that which happened to their curator.

Culture of Neapolitan Violets.—Early in April, or as soon as the plants are out of bloom, if they are in a frame, lift them; but if they are in pots, shake them out, and divide them into single crowns, removing all runners, and choosing only the most healthy plants. In a well-prepared piece of rich ground, with an east aspect, plant them out nine inches apart, and press the soil firmly about the roots. After they begin to grow, loosen the soil frequently with a hoe, and in hot, dry weather syringe the plants with clean water in the afternoon. All runners should be removed as they appear. In the first week of September they should be lifted, and potted in six-inch pots, placed in a cool airy greenhouse or pit, or a bed may be sunk two feet in the ground, filled up with dung, treading it well, to prevent too violent a heat, and placing over it a foot thick of good rich soil, mixed with leaf mould. Then lift the plants carefully, preserving a good ball of earth to each; plant them

in rows rather closely, but do not allow them to touch each other. The foliage should be within two or three inches of the glass. After planting, give them a good soaking of water, and in October allow them the benefit of warm showers, by withdrawing the sashes. Give them air as often as there is a chance, removing the sashes altogether on mild days, and tilting them up at night. They should not be allowed to get frozen, as that would retard their blooming season.—ALPHA.

Alocasia metallica.—I have grown this for some time; but cannot get its beautiful leaves in such good condition as I could wish to see them. When should my plants be re-potted?—ALPHA.—[*Alocasia metallica* should be potted as soon as it shows signs of active growth, using a compost of two parts fibrous brown peat, one part old dry cow-dung, and one part fibrous loam, mixing through the whole a little charcoal, and using the compost in a rough state. After potting, place the plants in a bottom heat of 80°, and an atmospheric one of 63° by night, 75° by sun heat; maintain a nice moist atmosphere, and shade from bright sun. Give air very cautiously.]

PALMS.

The religious aspect of the Palm tree dates from a period long anterior to Christianity. Its economic importance among Eastern nations gained for it a proportionate degree of esteem and veneration. It is one of the earliest types of the mystical "Tree of Life"; and a representation of it as such occurs upon an Egyptian sepulchral tablet at Berlin, which is certainly older than 1400 B.C. A traditional form of it constantly appears in Assyrian sculpture. Another, but a much less general, belief points to the Palm as the Tree of the Forbidden Fruit; but, according to a Mohammedan tradition, Dates were among the three things which Adam was permitted to take with him when expelled from the Garden of Eden. Both Mohammedans and Jews employed the Palm as a sacred symbol; thus Mohammed ordered his followers to honour it as the sister of their father, and as having been created in Paradise from the same earth from which Adam was made. It was one of the Hebrew types of a good man; and, in a wider sense, of man generally, having but one head, which cannot be replaced, and, if removed, is fatal to the growth of the tree; and branches, which, if cut off, find none to fill the same position. Figures of Palm trees, covered with gold, were prominent among the ornaments of Solomon's Temple. Among the Jews, too, the Palm was an emblem of victory; and thus it was that its branches were strewed along the path of Jesus on His triumphal entry into Jerusalem. From this time it may be considered to have taken its place in Christian symbolism; and thus the victory of the Christian martyr is typified by the Palm branch, and its use in religious processions, as commemorating the brief triumph of our Lord, became general. An extended use of this symbolism is that given by an old writer, who, speaking of Palm Sunday, says it is so called "for bycause the Palme betokeneth vycotry, wherefore all Crysten people sholde bere Palme in processyon, in tokenzynghe that he [our Lord] bath foughthen with the fende our enemye, and hath the vycotry of hym."

It was, however, naturally impossible, especially in remote times, that in the northern parts of Europe branches of any Palm could be obtained in sufficient quantity for use in the ceremonies of Palm Sunday. The substitution, therefore, of other branches for them was at once recognized as a necessity, and to some of these the German lines refer which have been thus translated:—

"In Rome, upon Palm Sunday,
They bear true Palms;
The cardinals bow reverently,
And sing old psalms.
Elsewhere, those psalms are sung
Beneath the Olive branches;
The holly bough supplies their place
Amid the avalanches;
More northern climes must be content
With the sad Willow."

Curiously enough, the two trees which most frequently do duty for the Palm—the Yew and the Box—are not mentioned here; but before speaking further of them, an incident in connection with the use of the "true Palms" at Rome may be referred to. The village of Bordighera, near Nice, has the privilege of supplying them, and is indebted for the honour to a naval officer who was present at the ceremony of raising into the position which it now occupies in front of St. Peter's,

the Egyptian obelisk which formerly adorned Nero's Circus. The Pope (Sixtus the Fifth) forbade anyone to speak during the raising of the obelisk, lest the workmen should be distracted from their task. In the midst of the silence, the officer, observing the danger that the cords might take fire from the excessive friction, shouted out, "Wet the ropes." He was brought before the Pope, who showed his appreciation of his interference by asking him to choose his reward; and he desired that a monopoly of the Palms for the Vatican might be granted to him and his successors.

The Box is used very generally in France, where it is called "*le bois bénit*." The demand for it is so great, that in Paris alone the sale in the four days preceding Palm Sunday realizes about a hundred thousand francs. The principal supplies are obtained from Brittany and Auvergne, but other districts also contribute their quota. It would appear that in England Box was similarly employed in former times, as there is an entry in "Domesday Boke" of a person holding land on payment of a bundle of Box twigs on Palm Sunday. Many virtues were traditionally attributed to the "palm;" and in France the "blessed Box," which has been given by the priest, is kept in the house throughout the year. It is supposed to have the power of driving away evil spirits, and a sprig is placed at the head of the bed, and on the cradle of a new-born child. On the death of a member of the family, a "palm" is placed upon the body; and this is possibly the origin of the north of England custom of throwing sprigs of Box into the grave after a funeral. It seems to have been employed for temporal as well as spiritual benefit, and not always with the happiest result, if we are to believe the accounts given by Newton in his "Herball to the Bible." He says:—"I once knew a foolish cock-brained priest which ministered unto a certaine young man the Ashes of Boxe, being forsooth hallowed on Palme Sunday; . . . which woorthy, worshipfull medicinse (as he persuaded the standers by) had vertue to drive away the ague, and to kill the wormes. Well, it so fell out that the ague indeed was driven away; but, God knoweth, with the death of the poore young man."

Nowadays, the Yew is most generally employed in England as "palm," and is distributed as such in the London Roman Catholic Churches. Its use dates back to the beginning of the sixteenth century, or earlier. It has been suggested that the Yew trees which we so commonly see in churchyards may have been planted for the convenience of the Palm-Sunday observances; but this is very doubtful, especially as many of them are probably of older date than the introduction of the ceremony into England. In the Jura, Beech twigs are employed; and in Provence, and other parts of the south of France, Myrtle, Bay, and Olive are used.

The use of the Willow, which is very old among ourselves, seems to be almost confined to Britain. To it, as to the Box, its sacred employment was supposed to give especial virtues. Thus Barnaby Googe speaks of those who—

"Willow branches hallow, that they palmes do use to call.
This done, they verily believe the tempest nor the storme
Can neyther hurt themselves, nor yet their cattel, nor their corne."

Thus also in Germany "palms" laid crosswise insure safety from lightning and tempest. In the neighbourhood of London this is certainly the favoured representative of the Palm, and, on the proper day, many of the poorest people have a spray of Willow in their button-hole. It is also frequently placed in the porches of churches, and is exposed for sale in Covent Garden Market. So generally is it known as "palm," that even persons of average education believe it to have some affinity with the rightful owner of the name, and are surprised on being told that it is merely a Willow.

It would be impossible to enumerate all the customs and traditions attendant upon these various "palms," and still more so, to enter here upon an inquiry into the tree-worship of old and bygone days, which, in all probability, lies at the root of the matter. But, enough has been said to show that such traditions still linger among us, in spite of the prosaic times in which we live; and to show, too, the necessity of collecting and recording them ere they disappear before the advancing "march of intellect" and education.

THE ARBORETUM.

THE WEEPING WILLOW.

MANY families of trees in which but few of the species exhibit any kind of attraction which would warrant their being planted as ornamental objects may yet, in the features of a single member of the tribe, assume a growth and habit so distinctive as to mark it out at a glance as a most valuable and beautiful addition to the trees which we usually employ for landscape effects, either in wild scenery or in the garden. This applies more particularly to the Willow family, one of the most extensive known, which yet only possesses a few species which at once arrest attention on account of their singularly graceful aspect and elegantly drooping growth.

The Weeping Willow appeals at once to the eye as a thing of beauty, and is, without hesitation, accepted as the unrivalled queen of weeping trees. It has received the specific name *babylonica* from its supposed habitat on the banks of the Euphrates, near the site of the ancient Babylon. Recent researches, however, seem to indicate that it is of Chinese origin. Many species of Salix form important trees in regard to size, but they cannot be compared with the Weeping Willow either for gracefulness or general beauty. Others scarcely exceed the dimensions of shrubs—and several kinds are of such miniature growth as scarcely to exceed that of herbaceous plants. The smaller forms are found, among the last specimens of ligneous growth, at great heights in the alpine ranges of Europe, where their stems creep along under the surface

of the scanty soil, in search of protection as well as nourishment, only an inch or two of the plant venturing into the keen, freezing air. The family is so widely distributed that a few of its members are found even in the Arctic regions, a dwarf creeping species being abundant in Melville Island.

By far the greater number of the Salix family are European. Koch estimates the species belonging to extra-European countries at not more than seventeen, among which are the *Salix babylonica*, which is found, not only on the Euphrates, but on the shores of the Persian Gulf, in Asia Minor, in China, in Japan, and in the north of Africa. The period of its introduction into Europe is uncertain. Ranwenwolf, in the itinerary of his pilgrimage to the Holy Land, towards the close of the fifteenth century, is admitted to have been the first to give an unmistakable description of the tree; but probably, Tournefort was the first to bring plants of it to Europe,

having discovered it during his botanical researches in the Levant in the latter half of the seventeenth century. There are several conflicting accounts concerning its first introduction to the British Islands, some giving the credit to Mr. Vernon, an English merchant at Aleppo, who, as recently as 1730, sent it to his seat, Twickenham Park, where, it is on record, it was seen growing by Peter Collinson in 1748. In the "Hortus Kewensis," however, the date of its introduction is unhesitatingly stated as 1692. Another account gives Pope the credit of having planted the first Weeping Willow ever seen in England. It is well known that in the latter half of the last century, a noble Weeping Willow, of mature growth, existed in the garden of the house still called "Pope's Villa," at Twickenham, the retreat in which the poet passed the later years of his life. The subsequent owner of the villa, finding the visits of persons requesting to see Pope's favourite tree an inconvenience, cut it down; and in the *St. James's Chronicle* of 1801, the story of the destroyed tree is thus related:—"Being with Lady Suffolk at the time that she received a package of plants from Turkey, Pope noticed that one of the withes with which it was bound was still green. He planted it in his garden, where it struck root readily, and, as it developed its graceful growth, became his favourite tree."

Either the tree must have been known in Shakespeare's time, or else the common brook-side Willow, whose lower branches are often wet and dripping, must have been generally accepted as an emblem of sorrow before the weeping species, with its more beautiful characteristics, displaced it as a symbol. If this were not so, we should not find Shakespeare speaking of the Willow in connection with the grief of Ophelia;

nor should we have had the exquisite passage in the "Midsummer Night's Dream,"—

In such a night
Stood Dido, with a willow in her hand,
Upon the wild sea bank, and waved her love
To come again to Carthage."

The Weeping Willow of the Euphrates is also alluded to most unmistakably in the Psalms, as pointed out by Sir Thomas Dick Lauder, in the passage relating to the captivity of the Jews: "By the waters of Babylon we sat down and wept"; and it is further related that they hung their harps upon the willow trees that were there. It has often occurred to me that the drooping branches of the Babylonian Willow, falling towards earth or water in a shower of tender grass-green foliage, explain very naturally the meaning of the "hanging gardens of Babylon," mentioned by ancient writers.

The Weeping Willow (*Salix babylonica*).

Some have imagined the existence of garden terraces, suspended one above another, from the level of the river upwards, to be a sufficient explanation. Others have endeavoured to show that there were gardens, after their kind, on the flat roofs of the houses, as is not uncommon in the East, and that such gardens seen by the soft light of an eastern night, with human figures moving among the shrubs, may have seemed to an ardent Oriental imagination like gardens suspended in the air. But the supposition that the chief gardens of the great city followed the course of the river, and that the most conspicuous objects were most probably glorious Willows hanging down their streaming branchlets of green till they swept the "waters of Babylon"—those of the Euphrates—seems a more rational explanation of the vexed question as to the meaning of "hanging gardens."

The Chinese, it may well be supposed, were not uninfluenced by the peculiar beauty of the drooping Willow; and doubtless they have their legends concerning its origin, though we are unacquainted with them. At any rate, we know for certain that their artists perceived its beauty; for we have endless proofs, not only in our old blue and white "swallow pattern" plates and dishes, copied from a Chinese model, but in a multitude of their decorative designs of all kinds, in which it is continually introduced as a conspicuous feature. That they used it as a symbol of grief and weeping in their cemeteries is plainly shown by a drawing made by Newhof, at the village of Tonman, while he was attached to the Dutch Embassy at Pekin, in 1655; while other examples of its use in that character are shown in the views of the "Vale of Tombs," published in Dobell's "Travels in China." In the North of Africa it is also common as a symbol of sorrow in the native cemeteries near Algiers.

The climate of England appears admirably suited to the Weeping Willow. The noble examples of it which ornament the banks of the Thames, are as finely grown as any ever described in its native habitats; and they are also far more numerous than on the banks of the Euphrates, where they are becoming rare. Many of the specimens growing near the course of the Thames have attained from fifty to sixty feet in height, and it is said that some, in the broadest extension of the branches, measure fully eighty feet across. One of the largest Weeping Willows in England is that at Finborough Hall, Suffolk, now about a century old, which is near seventy feet in height, and still in full vigour. That the climate of Scotland is not too cold for it, is proved by the noble tree at Taymouth, in Perthshire, described by Loudon, which, when seen by him, was seventy feet high, though it had only then been planted thirty-six years.

With regard to the use of this Willow in plantations, or as a single ornamental tree, Loudon observes: "The Weeping Willow spoils a landscape when injudiciously planted"; that it is not adapted for sublime effect, but better suited to the character of a pretty sylvan glade, with water; or in a villa garden, drooping over a picturesque rustic bridge. He would not introduce it in close connection with majestic ruins; such offices, he remarks, must be resigned by it, in favour of "the oak, whose dignity can fitly support such contiguity." He is doubtless entirely right in the broad principle; a plantation of Weeping Willows, for instance, would entirely destroy the effects of the glorious ravine of the Tete Noire; and of any scene of that sublime and majestic character. But in the grounds of ordinary residences, at well selected points near our park lakes, and in a hundred other situations connected with home scenery and the general characteristics of landscape gardening, it forms an element of beauty such as no other tree could supply. Even in winter its delicately drooping branchlets form a charming contrast to the more sturdy ramifications of erect-growing trees, and when they are feathered with hoar frost, the effect is striking in the extreme, drooping as gracefully as the wings of a bird of Paradise.

H. N. H.

Stone Picking.—In Mexico the custom is, when a duel has been fought, to erect a cross on the spot, and everyone that passes by throws a stone at the cross. Some ingenuous Yankees have taken advantage of this custom to clear stony land, by erecting crosses where no duel has been fought, and in that way have succeeded in getting stone picking done for nothing.

THE MONTEREY CYPRESS AS A HEDGE PLANT.

The value of this evergreen Cypress (*C. macrocarpa*) for making hedgerows cannot be well known, or we should often see it brought into use for that purpose. For many years yew was the only tree used for dwarf hedges. Latterly the Siberian variety of *Arborvitae* has been employed in many places for wind screens, and for divisions of plots in gardens. But for such purposes nothing that I have ever seen equals the Monterey Cypress. Plants two years old are usually from two to four feet high, and this is the best size to plant for a hedge-row. They should be planted two feet apart, and as they grow the tips of the laterals should be trimmed off periodically on each side of the intended hedge. If this is done regularly, the hedge will soon form thickly and evenly to any height that may be wished from four feet to fourteen feet high; but if this side pruning is not commenced early, the trees will not always feather to the ground, and will thus look bare and brown below. Fine specimens of hedgerows of this Cypress may be seen in Mr. Scott's nurseries, at Chichester. One row in particular is very handsome; it was planted about eight years ago (from seed sent from California in 1862), and is now fourteen feet high and nearly three feet thick. From the pruning having, however, been begun at too late a period, the hedge is thicker, and not so evenly furnished as it might have been; nevertheless it is an interesting example for reference, showing what to do and what to avoid. Trees from the same batch of seed (consequently ten years old), planted singly in the same grounds, are now twenty-four feet high, and feathered to the ground. Compared with yew hedgerows of the same age, those of the Monterey Cypress are more than twice the height, and of a lively cheerful green, instead of a dull, gloomy shade of that colour. As is well known, there are several varieties often produced from the same lot of seed, some seedlings showing a closer habit of growth than others, and these of course should be selected for hedge-making. I do not remember to have seen a plant of it in fruit before in the south-eastern counties, but there is one in Mr. Scott's grounds not more than twelve feet high, which has on it a quantity of fine fruits, one of which upon being cut open was found to be full of good seeds, though not yet ripe. This Cypress, I may add, is not liable to be injured by rabbits.

W. T.

THE MISTLETOE OF THE ANCIENTS.

It is a little singular, that in an age when botanical research has spread such rich and varied treasures before us, and when a longing for everything new and curious in the plant world has become the fashion, that so interesting a plant as the mistletoe of the ancients (*Loranthus europaeus*) should still remain a stranger to our arboreta and pleasure grounds, especially when we consider the facility with which it could be transferred from the oak forests of Austria, Hungary, and Italy to those of Britain.

The *Loranthus europaeus* is generally considered by writers to be the mistletoe of the ancients, on account of its being only found on the oak in a natural state; while our mistletoe (*Viscum album*) is rarely to be seen growing on that kind of tree. The mistletoe known to the Greeks and Romans appears always to have been found plentiful on the oak, and consequently must be the *Loranthus*; while our mistletoe (*Viscum album*) is scarce in Greece and Italy, and very rarely found growing on the oak in any part of Europe. Dr. Sibthorp says that the oaks on the Arcadian mountains in Greece presented him, with abundance of the true ancient mistletoe (*Loranthus europaeus*), whilst the mistletoe of England (*Viscum album*) was only seen growing on the silver fir, and there not plentiful. In Holstein and some other parts of Germany, even at the present day, the peasants call the *Loranthus* the "spectre's wand," from the supposition that holding a branch of it in the hand will not only enable a man to see ghosts, but force them to speak to him.

The *Loranthus europaeus* of Linnaeus is a hardy parasitical shrub, found plentifully in the oak forests of Austria, Hungary, Greece, Italy, and in parts of Germany, where it forms a glabrous, much-branched evergreen, two or three feet high, with a habit of growth very much resembling that of our common mistletoe. The leaves are spirally arranged in opposite pairs, leathery, and considerably longer and broader than those of the *Viscum album*; the flowers are produced in May in simple terminal racemes, and mostly in sixes, diocious. The petals are linear, reflexed, in sixes, and yellowish green. The berries are oval, one-celled and one-seeded, pale yellow

about the size of, or a little larger than those of *Viscum album*, and ripe in December.

The *Loranthus europaeus*, like the mistletoe, possesses the remarkable quality of having the power of rooting on the wood of the plant at whose expense it lives. The roots of the *Loranthus*, however, in all cases, only penetrate the inner bark and soft wood, where the sap is in most abundance; and as the tree on which it grows advances in growth, the roots of the parasite become embedded in the solid wood, each fresh layer of wood covering up, as it were, the roots of the parasite, and at the same time fixing the plant firmer on its foster parent; hence has arisen the opinion entertained by some writers, that the *Loranthus* not only roots into the bark, but also into the solid wood of the tree upon which it grows. The habit of our common mistletoe gives a very good idea of how the *Loranthus europaeus* grows and is propagated in a state of nature; for, like our mistletoe, it is increased by the berries being by some means or other made to adhere to the bark of a living branch; and the common agency by which this is effected is supposed to be birds. The seeds of the *Loranthus*, however, in a state of nature only require to be placed externally on the young smooth bark of an oak; but if artificially treated, they may be put into a cleft, or in a small hole bored in the bark, which seems to have been the system first adopted by Professor von Martius.

The *Loranthus* might easily be introduced into Britain by procuring a box of the fresh berries from any of the oak forests of Austria, Hungary, or Italy, any time from the middle of December to the beginning of March; afterwards treating them as we would those of common mistletoe—selecting of course a vigorous young oak for their foster-mother; for the principal thing requisite to ensure success is that the bark on which the seeds are placed be young, smooth, and not much indurated, otherwise the seeds will not root into it. Failure, however, will also arise from the seeds not being fecundated; but this may in a great measure be guarded against, by collecting the berries from different plants in the Austrian forests.—

George Gordon, A.L.S., in "Field."

SEASIDE PLANTING.

I AM a squatter on the cliff at Westgate-on-Sea, midway between Birchington and Margate, on the northern shore of Thanet. There, between the London, Chatham, and Dover Railway line and the sea, is an undulating plain, rising and falling at short distances, about half a mile in breadth and seven miles in length. There is a kind of crop that flourishes wonderfully on that small belt of land, I mean the blooming, bellowing scions of the human race; together with clover, cinquefoil, and weeds, especially the latter; but we have few shrubs and no trees. Now it occurs to me that the reason why we have no trees is that none have been planted; and if the vigour of the native population of weeds and "pusley" may be taken as a proof of the richness and capabilities of the soil, trees, if they had ever been planted, would have had no reason to complain. Trees can, without doubt, get a good root-hold; but the north-east and north-westerly winds are cruelly cold, and take no trouble to disguise the fact. Now, I have just been "planting," under the advice of a local descendant of Adam; and we have been lavish in the matter of Euonyms, Laurels, Laurustinus, Hollies, Bays, Snowberries, &c., not forgetting our old and tried friend the Tamarisk. Our ambition has also led us on to apples and pears, currants and gooseberries, elms, ashes, poplars, and thorns, lilacs, laburnums, Berberries, and Syringas; and some local experience has caused us to add larches and the Austrian Pine. The word that touches our hearts most responsively is "hardy." We are a hardy race, and if you send us your children we make them hardy, and that as a matter of course. What with oxygen and ozone, both of which we import direct from the North Pole and German Ocean, our appetites are prodigious, and we renovate and strengthen accordingly.

So much with regard to ourselves, and by way of introduction; but now we approach THE GARDEN as petitioners. Mr. George Gordon appears to be the man especially made for us; and may we ask of him the especial favour of a few lines bearing on our interests? I already see the Halimodendron argenteum stretching out its silvery fingers into our lovely sky, as if it would entangle the cheery larks that have learnt to sing a perpetual hymn for our enjoyment; while the dear bright *Euonymus americanus* makes us already feel warm in its glowing fires, chastens our chilly winds, and defies our hyperborean blasts. The dwarf forms of the shrub would be the

most likely to suit us best. But will Mr. Gordon be so kind as to tell us where we can get them? Will he help us to raise a garden forest along our beautiful cliff, to prove that heaven and earth are superior in strength to the intermediate forces that try to thwart our well-meant intentions?

To make gardens where gardens grow spontaneously were no remarkable phenomenon; but to raise a garden where nature seems to say "no," whether coyly or truly I am anxious to prove, were indeed worthy of the nascent and permanent celebrity of THE GARDEN.

MARSH BAY.

HARDY TREES AND SHRUBS.

THE LARGE-FLOWERED ROSE ACACIA (ROBINIA MACROPHYLLA).

This is a magnificent deciduous, rambling, loose-growing shrub, which grows from six to ten feet high in any good garden soil, and flowers profusely in the beginning of June, but keeps on blooming more or less till October. It is a native of the Southern States of North America, where it grows on mountains, and is quite hardy. It was first introduced in 1812. It requires to be trained, either to open trellis-work, or to be securely supported by stakes, to which the principal branches should be annually fastened; otherwise its brittle boughs are liable to be broken and disfigured by wind, when clothed with foliage in the summer and autumn.

The leaves are comparatively large, alternate, pinnate, deep green, smooth and deciduous, with ovate-roundish leaflets, mostly in eight pairs and an odd or terminal one. Branchlets quite smooth, robust, tortuous, and of a purplish-brown colour. Flowers large, pea-shaped, deep rose, scented, set several together on axillary nodding loose racemes. Fruit, a flattened pod, nearly stalkless, many seeded, and brown when ripe in September. This Acacia is increased by means of seeds, or by grafting it on the common Robinia. It deserves a place in every pleasure ground, however limited, and if the points of the principal shoots are pinched off when they are about half grown, say about the end of June, the plant will be less liable to be broken by wind; the operation also tends to induce a second crop of flowers in the autumn. Its synonyms are *Robinia grandiflora* and *rosa*.

G. GORDON, A.L.S.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Trees and Shrubs on the Chalk.—Would you or any of your readers tell me what ornamental trees and shrubs I may venture to plant on the chalk?—SOUTH DOWNS.—["Peverell," in Field, finds the following well:-]

Removal of Trees at End of Tenancy.—Does any law exist between landlord and tenant as to the removal of trees planted by a tenant where no agreement had been made between them previously to the tenant's leaving? or is it not usual for the landlord to pay the price of trees and shrubs at the time when planted?—**JESSE WOOD.**—[The landlord, we believe, can claim them without paying for them, except where the tenant is a nurseryman, and the things planted are part of his stock-in-trade.]

Photinia serrulata.—This bold evergreen shrub is not so often planted as it deserves to be. Its rosy-chocolate young leaves, now four or five inches long, clustered together at the apex of every branch, form a pleasing contrast to the dark green foliage of the previous year, which hangs just below the newly-formed leaves. Planted amongst other evergreens, it shows out much more advantageously than when placed by itself, since, from its growth being terminal rather than lateral, its "bare legs" (having not even a fig-leaf to cover them) require to be hidden by dwarfed shrubs in front. It is, I find, increased by grafting on quince stocks. It is said to be one of the most valuable seaside shrubs we possess; and I am told that there is at Hayling Island, near Portsmouth, a fine bush of it, at least forty feet in diameter, in the form of a cone, growing within two hundred yards of the sea, the size and vigour of which prove that neither strong winds nor salt spray have the slightest prejudicial effect on it.

W. T.

THE LIBRARY.

FOREST LIFE IN ACADIE.*

It is not often one meets with a sportsman's book which shows the author to take much interest in anything but the immediate objects of his search. Very rare, indeed, is the photographic eye, with the requisite power of recording its impressions, possessed by the authors of such books as that before us. Of the possession of these by Captain Hardy we have excellent evidence in "Forest Life in Acadie." The author seems to us to have a better faculty of observation and power of description than many men widely known to fame as writers on natural history. Take the following account of that graceful and remarkable tree the Hemlock Spruce—too much neglected in these islands:—

"The Hemlock, or Hemlock Spruce (*Abies canadensis* of Michaux), is a common tree in the woodlands of Acadie, affecting moist mossy slopes in the neighbourhood of lakes, though generally mixing with other evergreens in all situations. It is found, however, of largest growth (eighty feet), and growing in large groves, principally in the former localities, where it vies with the white pine in its solid proportions. The deeply grained columnar trunk throws off its first branches some fifty feet above the ground, and the light feathery foliage clings round the summit of an old tree in dense masses, from which protrude the bare twisted limbs which abruptly terminate the column. Perched high up in its branches may be often seen in winter the sluggish porcupine, whose presence aloft is first detected by the keen eye of the Indian through the scratches made by its claws on the trunk in ascending its favourite tree to feed on the bark and leaves of the younger shoots.

"Large groves of hemlock growing on woodland slopes present a noble appearance; their tall columns never bend before the gale. There is a general absence of undergrowth, thus affording long vistas through the shady grove of giants; and the softened light invests the interior of these vast forest cathedrals with an air of solemn mystery, whilst the even spread of their mossy carpet affords appreciable relief to the footsore hunter. The human voice sounds as if confined within spacious and lofty halls.

"Hemlock bark, possessing highly astrigent properties, is much used in America for tanning purposes, almost entirely superseding that of the oak. Its surface is very rough with deep grooves between the scales. Of a light pearly grey outside, it shows a madder brown tint when chipped. The sojourner in the woods seeks the dry and easily detached bark which clings to an old dead hemlock as a great auxiliary to his stock of fuel for the camp-fire; it burns readily and long, emitting an intense heat, and so fond are the old Indians of sitting round a small conical pile of the ignited bark in their wigwams, that it bears in their language the sobriquet of 'the old Grannie.' The hemlock, as a shrub, is perhaps the most ornamental of all the North American evergreens. It has none of that tight, stiff, old-fashioned appearance so generally seen in other spruces: the

graceful foliage droops loosely and irregularly, hiding the stem, and, when each spray is tipped with the new season's shoot of the brightest sea-green imaginable, the appearance is very beautiful. The tree has a wide range in the coniferous woodlands of North America, extending from the Hudson's Bay territory to the mountains of Georgia."

More striking still—and as we can testify from personal experience, true as life itself—is the sketch of an American forest:—

"On entering the woods, the first feature which naturally strikes us is the continual occurrence of dense copses of young trees, where a partial clearing has afforded a chance to the profusely sown germs to spring up and perpetuate the ascendancy of vegetation, though of course in the struggle for existence, but few of these would live to assert themselves as forest trees. Unhealthy situations, such as cold swamps, are marked by the utmost confusion. Everywhere, and at every variety of angle, trees lean and creak against their comrades, drawing a few more years of existence through their supports. The foot is being perpetually lifted to stride over dead stems, sometimes so intricately interwoven that the traveller becomes fairly pounded for the nonce. This tangled appearance, however, is an attribute of the spruce woods; there is a much more orderly arrangement under the hemlocks. These grand old trees seem to bury their dead decently, and long hillocks in the mossy carpet alone mark their ancestor's graves, which are generally further adorned by the evergreen tresses of the creeping partridge-berry, or the still more delicate festoons of the capillaire. The busy occupation of all available space in the American forest by a great variety of shrubs and herbaceous plants, constitutes one of its principal charms—the multitudes of blossoms and delicate verdure arising from the sea of moss to greet our eyes in spring, little maple or birch seedlings starting up from prostrate trunks or crannies of rock boulders, with wood violets, and a host of the spring flora. The latter, otherwise rough and shapeless objects, are thus invested with a most pleasing appearance—transformed into the natural flower vases of the woods. The abundance of the fern tribe, again, lends much grace to the woodland scenery. In the swamp the cinnamon fern, *Osmunda cinnamomea*, with *O. interrupta*, attain a luxuriant growth; and the forest brook is often almost concealed by rank bushes of royal fern (*O. regalis*). Rocks in woods are always topped with polypodium, whilst the delicate fronds of the oak fern hang from their sides."

We have rarely enjoyed a book more; and hope that circumstances may permit Captain Hardy to again use his pen to so gracefully sketch for us trees and forests new. Such a writer is worth a dozen of mere echoes of technicalities, who frequently seem divested of all feeling or high intelligence on the subjects on which they write.

The Chandos Classics. (London: Warne & Co.)—A shilling edition of our great writers, each volume well printed on good paper and in clear readable type. Shakespeare or Byron for a shilling has hitherto been considered remarkable, even though presented in the smallest type, and on the worst paper, but each volume of the Chandos series is really worthy of binding. The "Chandos Classics" are, in fact, the best product of cheap publication we have yet seen; and, specially merit the attention of gardeners and others whose means will not allow them to purchase costly editions of our greatest authors. The series comprises up to the present time the works of Moore, Byron, Burns, Longfellow, Scott, and "The Arabian Nights," each complete in one volume.

ENGLISH FOOTPATHS.

AND there are other simple footpaths, which I remember loitering through day after day, in the rural districts of England, with a sense of enjoyment that never belonged to saunterings in the alleys of Versailles. A man does not know England, or English landscape, or English country feeling, until he has broken away from railways, from cities, from towns, and clambered over stiles, and lost himself in the fields.

Talk of Chatsworth, and Blenheim, and Eaton Hall! Does a man know the pleasure of healthy digestion by eating whip-syllabub? Did Turner go to Belvoir Castle park for the landscapes which link us to God's earth? What a joy and a delight in those field footpaths of England! Not the paths of owners only; not cautiously gravelled walks; but all men's paths, where any wayfarer may go; worn smooth by poor feet and rich feet, idle feet and working feet; open across the fields from time immemorial; God's paths for his people, which no man may shut; winding—coiling over stiles—leaping on stepping-stones through brooks—with curves more graceful than Hogarth's—hieroglyphics of the Great Master written on the land, which, being interpreted, say—Love one another.—*Ib. Marvel.*

* "Forest Life in Acadie. Sketches of Sport and Natural History in the Lower Provinces of the Canadian Dominion." By Captain Campbell Hardy, R.A. London: Chapman & Hall.

THE FLOWER GARDEN.

HARDY CLEMATISES.

ALLOW me to say a few words in praise of these beautiful plants, which are so remarkably effective for decorative purposes in general. It is, however, more particularly of their adaptability for parterre embellishment, or association with plants of picturesque aspect, that I would now speak. When grown in masses they flower profusely for months, producing crimson and purple tints unequalled by any other class of bedding plant.

To grow Clematises successfully, so as to insure continuity of bloom, we must promote a vigorous growth, and the ground should be well drained, if at all wet; it should also be deeply wrought, and rendered friable; and rotten manure and leaf-mould should be freely added, raising the beds above the ground level, rounding them neatly off towards the centre, and planting about three feet apart. This is a good time to put out plants from pots, as they seldom receive any check if planted now. To insure a good effect the first season, it is important to procure thoroughly-established plants, as disappointment often accrues from planting weakly plants; and should it be necessary to plant between the Clematises other plants to cover the ground the first season, Verbenas are best for that purpose. Timely attention to training is necessary; if that is not attended to, Clematises soon become so tangled that it is difficult to separate them.

Propagation is readily effected by means of cuttings at any time during the spring months, when cuttings may be taken about three inches in length and struck in heat under a bell glass. Propagated in this manner, I find them to do equally well as grafted plants.

GEO. WESTLAND, Willey Court.

EARLY HARDY FLOWERS.

THE following list of hardy plants that have flowered here during the month of February may perhaps interest some of your readers, and perhaps induce them to send you similar lists.—

<i>Forsythia suspensa</i>	<i>Cytisus japonicus</i>
<i>F. viridisissima</i>	<i>Lamium flexuosum</i>
<i>Gaianthus nivalis</i> , single and double	<i>Borage orientalis</i>
<i>G. plicatus</i>	<i>Pulmonaria officinalis</i>
<i>Rhododendron atrovirens</i>	<i>P. o. alba</i>
<i>Hepatica trifolia</i> , white & red	<i>E. codonoides</i>
<i>H. s. s. double</i> , blue & white	<i>V. c. major</i>
<i>H. d. dito</i>	<i>Ulex europeus</i>
<i>Crocus sativus</i>	<i>Garrya elliptica</i>
<i>C. lageniformis</i>	<i>Cherianthus Cheiri</i>
<i>C. imperati</i>	<i>C. double yellow</i>
<i>C. lutes</i>	<i>B. Bocconi</i>
<i>C. l. striatus</i>	<i>Daphne pontica</i>
<i>C. bulbosa</i>	<i>D. genkwa</i>
<i>D. Parkinsonii</i>	<i>D. indica rubra</i>
<i>S. Sieboldii</i>	<i>Ficaria alba</i>
<i>C. vernis</i> , in var.	<i>Hyacinthus orientalis</i>
<i>Mahonia japonica</i>	<i>Heleborus niger</i>
<i>M. Aquifolium</i>	<i>H. n. major</i>
<i>A. betulifolia</i>	<i>H. dumetorum</i>
<i>A. alpina</i>	<i>H. kotschyi</i>
<i>A. graeca</i>	<i>H. n. nigrum</i>
<i>A. rotundata</i>	<i>H. orientalis</i>
<i>Viola canina</i> , white & blue	<i>H. atrorubens</i>
<i>V. Czar</i>	<i>H. fortidus</i>
<i>Erythronium</i> Dem. <i>canis</i> , white and purple	<i>Eranthis hyemalis</i>
<i>Dodecatheon</i> Epipactis	<i>Narcissus pseudo-Narcissus</i>
<i>Saxifrage</i> polycarpa	<i>sus</i>
<i>Thlaspiago fragrans</i>	<i>N. p. pleno</i>
<i>Lencium verum</i>	<i>N. minor</i>
<i>L. pulchellum</i>	<i>N. maximus</i>
<i>Lonicera fragrantissima</i>	<i>N. white polyanthus</i>
<i>Viburnum Tinus</i>	<i>Iris reticulata</i>
<i>Bitton Rectory, Gloucestershire.</i>	<i>I. stylosa</i>

H. N. ELLACOMBE.

[We shall be greatly obliged if other readers will add to this most interesting list of very early hardy flowers.]

THE FERN SUMACH.

(*Rhus glabra laciniata*.)

THIS variety of the smooth or scarlet Sumach is a small shrub with compound leaves, growing from four to seven feet high, a native of North America, with finely-cut and elegant leaves. These leaves combine the beauty of those of the finest Grevillea with that of a fern frond, while the youngest and unfolding leaves remind one of the aspect of a graceful umbelliferous plant in spring. The variety observable in the shape, size, and aspect of the foliage makes the plant charming to look upon, while the midribs of the fully-grown leaves are red, and in autumn the whole glow off into bright colour after the fashion of American shrubs and trees. Its great merit is that, in addition to being so elegant in foliage, it has a very dwarf habit and is thoroughly hardy. When the flowers show after the plant is a few years old, they may be pinched off; but this need only be practised in the case of permanent groups or plantings of it. To produce the effect of a Grevillea, or a fern on a small scale, we should of course keep this graceful *Rhus* small and propagate it like a bedding-plant. Like most other shrubs, it has a tendency to branch; but to fully enjoy the beauty of the leaves it is best to cut down the plants yearly, as then the leaves given off from the simple erect stem are

Rhus Glabra laciniata.

much larger and more graceful. The figure, sketched early in August, represents a young plant little more than a foot high, which had been cut down to the ground during the spring of the past year. It may be most tastefully used in association with bedding-plants, or on banks in or near the rock-garden or hardy fernery, planting it in light sandy loam. The graceful mixtures and bouquet-like beds that might be made with the aid of such plants need not be suggested here, while of course an established plant, or group of three, might well form the centre of a bed. Planting a very small bed or group separately in the flower-garden, and many other uses which cannot be enumerated here, will at once occur to the reader. Some hardy plants of fine foliage are either so rampant or so top-heavy that they cannot be wisely associated with bedding-plants. This is, on the contrary, as neat a grower as the most fastidious could desire.

LONDON MARKET WALLFLOWERS.

THESE are just now abundant, and their fragrant flowers are eagerly sought after, especially the good old standard dark kinds, for none others will do for the London market. A yellow variety, or one approaching to that colour, is pulled up by the heels, and ruthlessly cast to the rubbish heap, so anxious are our growers to secure the orthodox dark strain pure and unblemished. The market wall-flower is not so deep in colour as Young's Blood-red kind, but its

petals are flatter, have more substance, and the colour is brighter, and, consequently, gayer. The habit of growth of the former is also better, being usually dwarf, branching, and in some cases so compact as to make excellent beds. I have found no difficulty in selecting kinds that are now, after nine months' growth, not more than six inches in height, and so make capital companion plants to the Belvoir Yellow variety, which makes such capital spring beds. The great thing with London growers is to get them into flower early, and to secure this, they sow seed in March along with their broccoli. The seedling plants are transplanted into quarters as early as possible, and, if the ground be good, a perfect mass of strong, well-wooded plants will be ready to endure the vicissitudes of winter. These will be sure to flower early, and the first cuttings are worth double, and even treble, what the flowers will fetch after the crop has become general. I cut a good handful of flowers from yearling plants as early as February 23rd; but these had been left standing where sown last spring. Generally, however, sowing in March, and planting out as soon as large enough to handle, is the best way to secure very early flowers.

Our country cousins seldom grow such rich-coloured strains as we metropolitans are favoured with; but, then, here much care has been exercised in the selection of the best colours, and thus good quality is assured.

A. D.

AN OFFERING OF WILD FLOWERS TO "THE GARDEN."

HASTE to the woods this balmy day,
And mark what Nature has that's gay
To fringe her robe of green;
Peeping from forth dead leaves you'll see
The dark-eyed Wood Anemone,
Meek messenger of Spring.

The Snowdrop, firstling of the year,
While on the trees no leaves appear,
Now cheers the wintry gloom;
No rival whiteness now is spread,
It lifts its modest, drooping head,
And tells us snow is gone.

The Blue-bell, on its slender stalk,
You fear to crush it as you walk,
So thickly spread anew;
It bows its head to mother earth,
Sheds on the ground that gave it birth
A grateful drop of dew.

Primroses in profusion flank
On every side the hedgerow bank,
Sprinkled with Violets sweet;
In harmony their colours blend,
How fresh the fragrance that they lend !
How lovingly they meet !

Daisies open their starry eyes,
And mock the starlight in the skies,
So bright the ground appears;
But when the stars shine out at night,
Dazzled by the radiant light,
They close their eyes in tears.

Now tastefully a garland twine,
And bind it round with Eglington,
Then seek Sylvanus' bowers;
Hang it upon his garden gate,
A rural wreath to anfeate
The cultivated flowers.

—ELIZABETH H. COOKE, *Glen Andred.*

FERN COLLECTING IN DEVONSHIRE.

BEING desirous of possessing a collection of British ferns, the season before last I paid a visit to Ilfracombe, thinking, like half the world, that I had nothing to do but walk out and find plants of Maiden-hair fern (*Adiantum Capillus Veneris*) growing on every bank and hedgerow, but I found myself mistaken; for now it is very hard to get a plant of it. Indeed, it is only on the cliffs it is found, and men have to be lowered by ropes, to enable them to gather it; so I had to content myself with getting a plant of it at a dealer's fernery, where the Maiden-hair may also be obtained growing in pieces of the natural cliff, which looks very neat and effective. Here I provided myself with one of those wonderful-looking weapons, a fern digger. There are not, as I have said, many ferns to be found within a walking distance of Ilfracombe; the

Crystal Sea Pools, with their host of living creatures, being the attraction of other kinds of collectors at that place.

I next went on to Lympstone, where my expectations in the way of finding ferns were more than realised. I shall name alphabetically those which I found, beginning with:

SEA SPLEENWORT (*ASPLENIUM MARINUM*).—This is a fern rather difficult to find hereabouts; but I was fortunate enough to get one small plant on Countisbury Hill, which, you may be sure, I took good care of.

BLACK MAIDEN-HAIR SPLEENWORT (*ASPLENIUM NIGRUM*).—This may be found growing in nearly every rocky place, on old walls, amongst stones, &c., on the road to the Water's Meet. It was while getting this fern I found my digger so useful, as nothing else would have passed in amongst the stones and rocks as it did. I also found some small plants of this fern in the Valley of Rocks at Lynton.

COMMON MAIDEN-HAIR SPLEENWORT (*ASPLENIUM TRICHOMAENES*).—Of this elegant little fern I found a good deal all along the roads to the Water's Meet and Countisbury Hill, also at a place near Lynton called Leddy Weild. It is nearly always found in some damp spot.

LADY FERN (*ATHYRIUM FILIX FEMINA*).—This is found growing on nearly every bank all through Devonshire, and plenty of it occurs all round about Lympstone and Lynton.

BLECHNUM SPICANT.—Of this I found large clumps on the little island at the Water's Meet, which is rather a hard place to get at, as it is only when the river is very low one can cross over.

THE MALE FERN (*LASTREA FILIX MAS*).—This is to be found all along the banks and dells, sometimes growing to a very large size, according to the age of the plant, and also, the soil.

BUCKLER FERN (*LASTREA MONTANA*).—This also is to be found plentifully on the hill that rises from the side of the river Lyn, on the right hand going from Lympstone, and also here and there along the side of the river.

HAY-SCENTED FERN (*LASTREA EMULA*).—This is not common round Lympstone; but I found two large plants near Countisbury, which I was told was a very rare occurrence, as where it is generally found is much further away.

COMMON POLYPODY (*POLYPODIUM VULGARE*).—This grows in great profusion on the top of the wall all along the hill up from Lympstone to Lynton, and also on the trunks of trees growing on the island at the Water's Meet.

PRICKLY SHIELD FERN (*POLYSTICHUM ACULEATUM*).—This is also very common in Devonshire. I have found it growing in many parts, sometimes of great size.

COMMON BRAKE (*PTERIS AQUILINA*).—This, I need not say, grows plentifully everywhere; but near the Water's Meet—indeed, close to it, beside the water—I have seen it more than eight feet high.

HART'S TONGUE (*SCOPOLPENDRUM VULGARE*).—This is found on nearly every wall or ditch throughout this county. There is one about forty yards long, on the road coach road between Ilfracombe and Lynton, which is literally one mass of this fern.

These include all the ferns I found, and let me hope that the indications of locality which I have given may serve as a guide to such of your readers as, like myself, go fern collecting in Devonshire.

A. H., *Upper Norwood.*

THE DEVONIENSIS ROSE.

UNTIL Mr. Hole raised the question I was not aware that there was any doubt about the English parentage of this rose. In addition to the valuable testimony of Messrs. Curtis and Brown, that it is of English origin, other correspondents have written to me confirming that fact. Mr. Rendle says:—"It was raised by Mr. Foster, a gentleman who was one of the officials in the Government Dockyard at Devonport. He had a very nice garden (I am speaking now of more than twenty years ago), and he was fond of raising seedlings. He raised some excellent Dahlias, including the Glory of Plymouth, a famous flower in its time. He also sent out some first-rate Geraniums. He had about forty or fifty seedling Roses trained against a south wall, and Devonensis was one of them. He paid the expenses of his garden, I must tell you, from the proceeds of his seedlings; and he wanted £50 for Devonensis. I thought this was too much, and offered £20. However, Mr. Pince of Exeter, saw it, and was so struck with it that he agreed to pay the £50. Mr. Pince soon set to work and raised a large number of plants, and I have heard that he made between £2,000 and £3,000 profit out of it. I remember the blooms were shown under glass shades, and made quite a sensation at the time."

D. T. F.

THE WILD GARDEN.

It is in scattered and unexpected places that I like my children to ferret out the wild flowers brought down from the woods—the frail Columbine in its own cleft of rock—the Wild-turpin, with its quaint green flower in some dark nook that is like its home in the forest—the Maiden-hair thriving in the moist shadow of rocks; and among these transplanted wild ones of the flower-fold I like to drop such modest citizens of the tame country as a tuft of Violets, or a green phalanx of the bristling Lilies of the Valley. Year by year, as we loiter among them, after the flowering season is over, we change their habitat, from a shade that has grown too dense, to some summer bay of the coppices; and with the next year of bloom, the little ones come in with marvellous reports of Lilies, where Lilies were never seen before—or of fragrant Violets, all in flower, upon the farthest skirt of the hillside. It is very absurd, of course; but I think I enjoy this more—and the rare intelligence which the little ones bring in with their flashing eager eyes—than if the most gentlemanly gardener from Thorburn's were to show a Dahlia with petals as regular as if they were notched by the file of a sawyer. Flowers and children are of near kin, and too much of restraint, or too much of forcing, or too much of display, ruins their chiefest charms. I love to associate them, and to win the children to a love of the flowers. Some day they tell me that a Violet or a tuft of Lilies is dead; but on a spring morning they come, radiant with the story that the very same Violet is blooming sweeter than ever, upon some faraway cleft of the hillside. So you, my child, if the great Master lifts you from us, shall bloom—as God is good—on some richer, sunnier ground!—*Ib. Marvel.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Rose Manure.—I have heard that if cabbage-leaves are mixed with the compost prepared for rose trees, they heighten the colour of the blooms. Would Mr. Reynolds Hole say whether this is correct or not?—M. L. W.

[Mr. Hole replies, that cabbage-leaves are very beneficial both in heightening the colour, and in increasing the size, of roses, if previously prepared by the pig.]

Linnaea borealis in London.—We were pleased to see this very interesting and uncommon plant thriving in the open border in Mr. Peacock's garden, at Sulbury House, Hammersmith, the other day. It is, of course, hardy enough to grow in any part of these islands, but we did not think it would grow in the smut of London unprotected. We have grown it freely in London under a clouded handlight, and also in a cold frame, but it is of course much more interesting seen thriving in the open air. A peat, or free moist soil suits it best.

Arundo conspicua.—I have some nice young plants of this, twelve months old from seed; can you inform me whether or not this plant will bear an average English winter in the open air? or does it require protection? May it be planted out in a clump like Gynerium argenteum?—R. M. R.—[Arundo conspicua will thrive in the open air in our southern counties, if on a well-drained sandy loam; but in all cold situations it ought to be protected. It forms a superb grass on good soils, but is more fondish than Pampas grass.]

Dampier's Glory Pea.—Mr. Saul, of Washington, has informed us that he raises this Pea with perfect success in the open air. He waits until the ground is well warmed—perhaps the end of May—and then sows the seed in not over-rich soil, in the place where the plants are to stand. It will not bear transplanting. The plant must be guarded from red spider in dry weather.—*American Agriculturist.*

Hardy Palms.—I shall be glad to know if there is a variety of Palm tree which would survive all the year round in an open garden, and where it may be obtained.—J. T. T., *Guernsey.*—[Yes; Chamaerops excelsa, and in your climate probably several others.]

Hardy Ferneries.—Being anxious to possess a fernery for native ferns, I should be grateful to any of your readers who would kindly help me with a few hints as to its construction and arrangement. The locality is in South Carnarvonshire, where the temperature is exceedingly mild. The spot chosen, the corner of a wood, partially overshadowed with trees. A bank about twelve feet high, extending for some distance into the wood, has at its foot a small winding brook, an old fence being on the other side of the brook, where common ferns now grow most luxuriantly. The steep bank I wish more particularly to make the groundwork of the fernery, by having it cut into and hollowed, &c. I have a quantity of cork bark, how can I make that available? Will ferns grow in it if placed as a facing to small terraces?—M. L. W. [Our correspondent seems already to possess a very happy home for ferns without much further alteration. We should not use cork bark in such a position.]

Abnormal Heaths.—Mr. Britten directs attention, in the *Journal of Botany*, to an anomalous variety of *Erica cinerea*, from Wiltshire, which has year after year brought forth similar blossoms. Their appearance is very remarkable, and due to the fact that both corolla and stamens were wanting. The specimens are interesting on account of their apparent permanence.

GREAT GARDENS OF EUROPE.

KEW.

In treating of this, the greatest of great gardens, we shall begin with its least praiseworthy feature—it's design. Competent writers, conversant with the various types of vegetation so well represented at Kew, will speak of these in detail; to ourselves falls the unwelcome duty of showing that in point of design Kew is chiefly remarkable for indicating what to avoid. Let it not be supposed, however, that Kew has anything like a monopoly of bad design; there are many botanic gardens worse laid out than it, notably the Paris gardens; but in the case of Kew the fault is perhaps the more glaring, as the great size of the place has not made necessary that overcrowding which is unavoidable in the numerous small botanic gardens scattered over Europe. A notion prevails that good design is not easily secured in a botanic garden, and sometimes that it is not desirable. No idea can be more erroneous, or more fraught with danger for public gardens. Any one who knows the private plant collections of the United Kingdom, is well aware that the finest and fullest collection is often also the most beautifully and effectively arranged. Take the case of alpine plants and filmy ferns, for example. Everybody knows that the finest collections of these are not only among the best arranged, but are disposed in an entirely novel and exquisitely beautiful manner; the fact is that when the true and natural mode of arrangement is applied, the nobler the collection the higher the aesthetic effects will prove, provided always there is space on which to display them. But no really good effects are possible in our botanic gardens so long as the system of ignoring the necessity of breadth, and of dotting about trees and shrubs prevails, as if the object was to prevent the free sweep of the poacher's net. The objects preserved in a botanic garden are in themselves so beautiful and interesting that, to numbers of persons, the necessity for a radical change in their arrangement does not present itself. And no language which we can employ can describe the enormous difference between a vast national botanical garden, so arranged that the various types of vegetation preserved therein would be seen to the greatest advantage, and one disposed in the ordinary manner.

Unfortunately, well designed large places of any kind are very rare. Not so small and medium sized ones, however; and if anyone will compare the difference between such gardens as those at Oak Lodge, or Berry Hill, with numbers of others badly laid out of the same size, he may form an estimate of the vast difference between the present aspect of our botanic gardens and that which they would present were a true system of garden design carried out in them.

It is, however, only fair to remind the reader of the vastly greater difficulties that the improver meets with in public gardens and gardens governed by a society or committee of any kind to what he does in a private one. The difference is like that between paralysis and healthy and vigorous power of movement. The best man of his time may, employed in a public garden, be so hampered by red tape, and so outmanoeuvred by the silly or ignorant interference of officials, committees, &c., that his best efforts may be neutralised. As a case in point, we may mention what came under our own observation a few years ago in a public garden governed by a council and committee. The superintendent of the winter garden, appalled by the leggy grandeur of a gigantic and aged Acacia in a tub, made up his mind to cut it down. Had it been in a private place, it would have been beheaded years before. The unhappy foreman knew his men, and did not appeal till the plant manifested a disposition to wander through the panes in the root into the free air of Britain. He did not get his pruning-knife to cut it down, but began with a smaller implement, and made a report. This was sagely pondered over at the next meeting by the committee, but notwithstanding the proverbial wisdom in the plurality of advisers, the momentous question could not be decided. One member, bolder than the rest, proposed that they should all proceed to the conservatory, there to finish the discussion; and, in the fulness of their wisdom, they went. One was a well-known racing lord, another a successful apothecary, another a retired merchant, another a clergyman, another a London police magistrate, and so on, all being utterly inno-

PLAN, SHOWING THE GENERAL DISPOSITION OF THE ROYAL GARDENS AT KEW.

cent of any knowledge of the cultivation of plants, and all, on a foolish mission, trying to determine a question which any gardener would settle in a few seconds. They returned to their meeting room once more, held a long consultation, and passed a resolution, that the specimen was too large to be cut down; and so it remained, as seedy-looking a grenadier as ever adorned a badly-managed conservatory. This may seem an extreme instance; but it is true, and may serve to show the lengths to which misdirected interference will go.

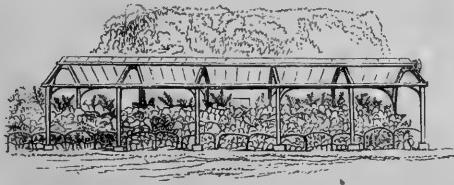

As we wrote a fortnight ago, we have good reason to believe that there is very unwise interference on the part of some officials in the management of Kew and some others of our most important gardens, not merely with their general management, but with details, for which the superintendent should be solely responsible. Be this the case or not, the influence of our great public gardens is so powerful, from their being visited by hundreds of thousands of gardeners and amateurs, who look to them as models, that bad or imperfect arrangement in them must have a pernicious influence throughout the length and breadth of the land; and we feel it our duty to point out their faults, so that they may be avoided. Our plan of Kew is necessarily drawn on so small a scale, that many of the details of the garden cannot be seen therein. But, as our object in the first instance is to speak of the general disposition of the gardens only, this does not matter.

Total want of breadth is the most glaring fault at Kew. The dotting system prevails everywhere. No improvement has been of late manifested in this direction. The place is gradually getting worse in this respect, and, in all our experiences, we have never seen so bad an example of injudicious dotting about of myriads of small trees and shrubs as Kew at present furnishes. Mr. Dawson, who drew our plan, tells us that in a few small plots in front of the winter garden he counted 1,500 small trees and shrubs, mostly ordinary kinds without character or manifest object. The immense importance of a little peaceful breadth may be seen by looking from the raised bed near the Palm House lake towards the group of tall Limes, a small bit of undotted foreground leading great charms to the view. The question of the management of the vista planting, recently discussed by our correspondents, is of no real importance compared with that of breadth. How the vistas are treated will make very little difference in the general impression produced on the visitor. A few acres of cool grass here and there would be worth a whole galaxy of canal-like vistas, managed even after the most approved fashion. In consequence of these vistas forming the chief feature, and of other reasons before given, it is out of the question to expect any radical alteration in the way of breadth. But we are entitled to expect that attempts should be made to secure it where possible, instead of destroying it whenever a change is made.

A needless kind of formality is also very apparent in many parts of the grounds. The kidney-shaped beds along the main walk are being multiplied without end. Now if the garden were wholly geometrical there would be some apparent excuse for this, but not a real one, for, as is well known, intelligent designers of geometrical gardens do not now hesitate to make one feature differ from another, although balancing each other. But these kidney-shaped beds abut right upon varied plantations. Such a long and heavy repetition of them was never in good taste, but to add to them, as has lately been done, is a real misfortune to the gardens. And those oft-repeated formal masses of Rhododendrons are likely to be quite surpassed in bad effect by a great number of formal masses of small Laurels bordering the walks in many directions. It is not easy to guess why these have been thought desirable, but no feature ever added to a public garden is likely to produce a worse effect from the point of view of design, or indeed from any other. To the north of the great conservatory another hideous kind of formality may be seen—beds, hundreds of feet long without a break. These are occupied by shrubs, and no doubt the arrangement is adopted to facilitate classification. But no worse or more awkward system could have been devised. Except one crosses the bed, a long detour has to be made to see any particular shrub that may attract the eye from a distance of twenty feet. Blanks appear much uglier than if the natural

system of grouping had been adopted; and the effect of the whole on the eye is detestable. No graceful arrangement of shrubs is possible in long, straight beds. In all cases of arranging trees and shrubs in a botanic garden, the system of irregular grouping of families on the turf is the true one. It permits of beautiful arrangement, of easy access to all the species; every kind of shrub or low tree may be fitted into a happy place in the group; and if deaths occur, as they frequently do in botanic gardens, they do not leave an ugly blank, as is the case where the subjects are arranged in formal lines or beds.

No garden should show anything in the way of rockwork which is not tastefully done, and is incapable of answering some useful end. This rule should particularly apply to botanic gardens. Better a thousand times content ourselves with the manifold good effects we can produce with trees and shrubs and flowers on the level ground than add to the hideous piles of rubbish that go by the name of "rockwork" all over the country. And where these excrescences do occur in public gardens, if the finances or other circumstances will not permit of a proper rock garden being made, the right thing to do is, convey the offensive pile to the rubbish yard some time when the ground is hard in winter, and labour plentiful. Few public gardens show worse examples of the traditional rockwork than Kew. Our sketch shows that on which the collection of

"Rockwork" at Kew.

alpine plants, &c., is shown in summer. It speaks for itself. What a check to progress in this direction are the "rockworks" here and in the Botanic Gardens in the Regent's Park! And yet there is no way in which our public gardens would do more good than by growing well, in the open air, and arranging in a tasteful manner, the numerous brilliant flowers of the mountains of our own and other cold and temperate regions.

(To be continued.)

NOTES ON PUBLIC GARDENS.

The Enlargement of Victoria Park.—The Victoria Park Preservation Society are renewing their efforts to obtain every available portion of the open spaces which remain around Victoria Park. At the instigation of the society, the Metropolitan Board of Works recently purchased about twenty-four acres of the Crown land for the park, including the land on the south side, and to the east of the Queen's Hotel. These portions were secured from the Government for £20,450. But, besides the portions of land which have been thus purchased on the north and north-west sides of the park, there are several plots of Crown land, amounting in the aggregate to about nine or ten acres. Some of these plots have passed into private hands, and their purchase having become a matter of some difficulty they were abandoned by the Metropolitan Board of Works. Last week a deputation waited on the Members for Hackney (Messrs. Reed and Holms), with a view of influencing them to induce the House of Commons to repurchase these plots. Mr. Holms, however, gave it as his decided opinion that the attempt to obtain the land would be useless, as both the Government and the country members would oppose the motion. The Victoria Park Preservation Society have therefore determined to urge the various local boards surrounding the park to combine for the purchase of the plots of land in question.

Driving in the Parks.—At present the parks are exclusively confined in respect to carriages to the use of the wealthy who have carriages of their own. This is not a condition of things which will bear discussion. I have given notice of a clause which will declare that persons who cannot afford the luxury of private carriag-

shall not on that account be deprived of the use of places of recreation supported out of the public taxation. I can see no reason why sick or feeble persons who are unable to walk should not be permitted to take the air in the parks in a hansom at half a crown an hour, as much as those who possess a barouche. Nor can I see why the pleasure vans, which seem to me productive of more real enjoyment than all the fine carriages in the world, have not as good a right in Hyde Park as the Four-in-Hand Club. They give pleasure to a greater number of people, and are, on the whole, I fancy, less dangerous to human life. I observe that one of your weekly contemporaries defends this distinction on the ground that the greatest enjoyment in life is that of gaping with wondering delight at fine people and smart equipages. I don't dispute that the writer accurately expresses his personal sentiments; but I fancy that this idle admiration of fashion is rather the weakness of the literary than the operative *Spectator*.—Mr. Vernon Harcourt, in "Times."

TREES ON THE THAMES EMBANKMENT.

The "rough" element of the lower stratum of our population still continues to exercise its propensity for the perpetration of wanton mischief. Twenty years ago, anything like decorative sculpture within reach of a formidable stick was certain to be mutilated in a short time after its exposure in a public situation; and this was all the more certain to be the case if it consisted of figures, the noses of which very soon disappeared, forming, as they did, most tempting targets to the rolicking savagery of our street Arabs, whenever a good opportunity occurred. The pretty little figures on the new gates of the Bluecoat School, in Newgate Street, soon lost their heads altogether, and the unicorn supporting one of the shields was docked of his twisted horn, and also of his tail, before he had been many months exposed to the rough favours of a certain class of our British youth, who are so energetically active in mischief while so sluggish in any kind of useful work. But our youthful gentry of the *parle* perceived at last that brutal depredations of the kind alluded to began to be visited with such heavy indignation by the better educated, that the untutored ruffians found the "fun" did not "pay," and reluctantly refrained. Or it may be that the influence of international exhibitions percolated even into the stony brains of raw ruffianism, and partially woke it up to a dim perception of the beauties of art. In whatever way the change may have been wrought, certain it is that it has been wrought. Nevertheless, the demon of mischief still holds to a certain extent his ancient sway; and although sculptured marble or artistic bronze is safer now than formerly, he sees no harm in breaking down or mutilating a young tree too trustingly placed within his reach. This fact has been disagreeably exemplified by the injuries inflicted for mere vicious amusement on the newly-planted trees of the Embankment, where this kind of depredation has been carried on to such an extent, and so daringly, that their official guardians, hopeless of affording them efficient protection by the police or by any other means, have, in a fit of natural vexation, threatened to take them away altogether. Such a course would be, in principle, like destroying any kind of property whatsoever if its protection happened to become irksome; and therefore the threat must only be regarded as a natural expression of angry disappointment—a mere *façon de parler*. H. N. H.

KEW GARDENS.

The week before Christmas upwards of forty gardeners were dismissed from Kew; says a correspondent in a recent number of the *Standard*, not because there was not plenty to do, but because from some muddle in the estimates, the money which should have been arranged for their pay, was not forthcoming. In that inclement season these unfortunate victims of mismanagement were, at a week's notice, ejected from the Royal employment, although Parliament votes liberal and abundant sums for the support of the gardens. "From some similar miscarriage in the estimates," says the same authority, "no fuel was this winter forthcoming for the museum, which was consequently perfectly useless to visitors. The damp and cold were such that it was more like a vault than a museum. Such a state of things at an institution for which is voted, I believe, £19,000 per annum, is utterly disgraceful, and yet, I suppose, we shall be told that no one is irresponsible or blame-worthy for it."—In reference to this statement the *Standard* of a later date, says: "We are assured upon good

- y. 1. That not a single gardener has been dismissed from Kew this winter. 2. That there has been no muddle or confusion in the descriptions in the estimates of any of its departments for the week; the payments having been rightly calculated month and week, nor has any weekly or other been miscalculated, or payment postponed. 3. Distinguished in one (only) of the three museums

—that to which reference is made—because of the warmth of the weather, and because any extra heat is injurious to the magnificent collections of polished timbers it contains. The doors of this building are set open whenever possible to attract visitors, who are apt to suppose that the building is closed when the doors (which resemble windows) are shut. 4. That there has been no lack of fuel, nor of money to buy more if required. It is only fair to state that there never has been any attempt at floral display in the Royal Gardens in winter, except in one conservatory, and in the orchid houses, which certainly never had more variety or gaiety than this winter. With regard to the dismissal of the gardeners, we are informed that the dismissed men were not gardeners, but day labourers, hired in excess of the staff, for the especial purpose of trenching and planting, and were all distinctly informed when hired, that they might not be wanted for more than a week or two, whereas they were kept on for a much longer period."

REVIVAL OF HORTICULTURE IN THE PUBLIC GARDENS OF PARIS.

THE horticultural branch of Parisian industry is now summoned to renew its too long intermitted labours with vigour, and the next month or two will witness the reparation of much of the devastation caused by the late disastrous siege and subsequent civil war. The shrubberies of the Champs Elysées, which were nearly destroyed, are being entirely replanted where necessary, and the expanses destined for turf, which were so beautifully kept before the war, are being carefully dug and levelled, and sown with suitable grasses. In short, this spring will see that favourite promenade reassume nearly all its wonted beauty. The shrubs will, however, require some few years before they can be expected to attain to that fullness and beauty of growth which distinguished the old plantations. Orders have also been issued for the immediate formation and plantation of a new square at the Tower of Jean Sans Peur, in the space which has been laid open by the prolongation of the Rue aux Ours and the opening of the Rue Turbigo. The open space is of considerable extent, and the plantation and accompanying decorations are intended to be in keeping with the importance of the site.

The remodelling of our London squares might be advantageously undertaken in emulation of the examples Paris will shortly afford us. In the midst of horticultural activity in Paris in many other directions, it is to be regretted that the carrying into execution of the plans for the fine "square" in the Place Dauphin is to be indefinitely delayed. However, much is being done; and the green spots in the bright gay Paris of old will soon look as they used to look, and several new features will be added during the present year.

PUNCH ON PARK MANAGEMENT.

To promote the study of natural science amongst the upper classes, once a week, during the months of May, June, and July, the Chief Commissioner will hold an afternoon Botanical Class in Hyde Park, and lecture on its trees, plants, and flowering shrubs, with the aid of the descriptive labels belonging to them. Ladies and gentlemen attending the class will have the option of taking notes, and passing an examination in the lectures at the end of the London Season, when prizes will be awarded to the most proficient students.

Within twelve months of the Bill receiving the Royal Assent, the group of Achilles at Hyde Park Corner, and the equestrian statue surmounting the Arch on Constitution Hill, will be removed to the middle of Hampstead Heath and Epping Forest respectively; unless, in the meantime, a requisition signed by the Presidents of the various incorporated Art Societies in the Metropolis, be presented to the Chief Commissioner, imploring him to retain these memorials of a nation's gratitude in their present positions.

The estimates for the financial year 1872-'73 will include a sum for replanting Primrose Hill with Primroses, Crocuses, Snowdrops, and other spring flowers. To lessen the expense to the nation, contributions of plants and bulbs are solicited. They will be thankfully received and officially acknowledged.

The design for any drinking fountain proposed to be erected in a Royal Park or Garden, must be approved by a Committee of Taste, to consist of a Royal Academician, a Fellow of the Institute of British Architects, an official of the Science and Art Department, the Editor of the *Art Journal*, Lord Elcho, Mr. Beresford Hope, and a prominent Tectotaller.

Smoking will be permitted in the Parks and Gardens, and encouraged in the Conservatories; but samples of the tobacco and cigars must be sent, ten days beforehand, to the Office of Works, which will submit them to the Customs, which will confer with the Excise, which will report upon them to the Treasury, which will consult the Board of Trade, and a decision will be given before the Parliamentary Recess.

No alteration will be made in the existing arrangements for the custody, preservation, and maintenance of the birds on the ornamental waters; but that the expense of keeping up the Parks may be reduced to the lowest point consistent with the national honour and dignity, as the present fowls die off, their places will not be filled up.

THE SIX OF SPADES.

CHAPTER VII.

UPON the occasion of our Curate's first appearance as a member of "The Six of Spades," I derived much gratification from contemplating the deportment of Joseph Grundy. No sooner did he see his Pastor, than he made an uncomfortable attempt to hide his pipe, which, being a Brocley of robust proportions, declined to be concealed at any price; while his features assumed, so far as their mirthful make permitted, a troubled and solemn aspect. Whether he thought it probable that he should be called upon to oblige the company with a hymn, or whether he was under the impression that clergymen were painfully affected by tobacco, after the manner of the green-fly, there was but brief time to speculate; for the Curate, noting his perplexity, forthwith proceeded to dispel it by filling and igniting a ample bowl of clay, and by taking his seat, next to Joseph, with a pleasant and friendly smile. "I met old Michael Willis yesterday," he said, "and as soon as he saw me, forgetting, I suppose, that he has not a monopoly of eyesight, he swiftly put his pipe in his pocket. So, after some little conversation, I suddenly expressed, to his great surprise, the anxious hope that he was insured. For if," I continued, "the old saying be true, that where there is smoke there is fire, your waistcoat-pocket, Michael Willis, may soon be ready for the tinder-box. And you would be rightly rewarded for doing that which you are ashamed of doing, and for attempting to deceive a true friend."

"I'm not ashamed o' smoking," lie answered, "but they do say as parsons hates it."

"Cruelly, despitefully, and with lying lips, Michael. With the exception of a very small company, not conspicuous for liberality or learning, the English clergy have never spoken against the moderate use of tobacco. The majority of them, smokers themselves, would hypocrites to do so; and of the remainder, they who go much among the very poor, and know how few their comforts, how many their hardships, must be glad to see the enjoyment (not the abuse) of a cheap and innocuous pleasure. They who denounce it must give up all their luxuries, and nearly all their comforts, before they can do so consistently; and then, Michael, we will argue the matter on the principles of religion and common sense. We have smoked our pipes for three hundred years in England, beginning with a walnut for a bowl and a straw for a tube; and, though a king has blown his "Counter-blast against Tobacco," and yellow Puritans have groaned and snarled at it, it still brings pleasant solace, throughout the land and under it—to the miner toiling for the coal, and to him who sits by the coal-fire's blaze; and leaves men as brave and as good, Michael, as when Raleigh, or whoever first brought the plant among us, was as yet unborn. So I finished my little sermon; and my friend Joseph knows why I have ventured to repeat it here."

"There's another little sermon, sir," said Mr. Oldacre, "upon tobacco and the pipe, which rescues the memory of one Puritan at all events from silly prejudices on the subject. I mean that quaint, touching old ditty which George Wither sang, and which Frank here" (his son-in-law, Chiswick) "will sing for you if you wish."

Whereupon was rapping of the table, and a preliminary sipping of gin and water, and a re-arrangement of limbs into the most easy posture for listening; and then Mr. Chiswick, with a voice very pliable and mellow, sang to us the impressive words and appropriate music of the well-known ballad, "This Indian Weed," &c.

And now, my brothers, do I feel glad at heart that I am writing for those who love a garden. I picture to myself some young Mr. Gallio Noodle, sightless and noseless so far as flowers are concerned, yawning over "The Six of Spades," and saying, "Whart a delightful convocation of snorbs! Parson

smoking clay pipes with groom, and dram drinking with the rest of the company, while melodious gent, who has been digging all day, and has come in, I dare say, all over worms, is hollering Bacchanalian songs." Let him sneer, as he tosses the volume down, and goes off with his cigar to the stables, for I am perfectly unconcerned and happy—happy in my earnest hope that they whose sympathies alone I crave, will recognize in our little assemblies that brotherly goodwill and amity, whereof themselves know from experience the excellent power and sweetness, and whereby the true lovers of a garden are united in a friendship as steadfast as it is pure, and as universal as Divine Beauty itself.

These lovers of the garden know well, that as "one touch of Nature makes the whole world kin," so one truthful instance of a floral taste, one hearty expression of horticultural loyalty, is acknowledged at once and echoed instantly by a thousand kindred souls. They know of signs and passwords more powerful than those of the Free-ston Masons, the Oddset Fellows, the most Ancient Druids—a cosmopolitan clanishness, accredited throughout the world.

"Rather flowery," I hear it suggested. Well, yes, I think so; and, therefore, let us put aside the figurative, and illustrate our theme by fact. One hit, straight and home, is worth half an hour of sparring.

Returning, not long ago, from a visit to some distant friends, I arrived at their nearest station four seconds after the departure of the train; and the engine-driver, to whom I bellowed pitifully, not being of a floral mind, and coarsely refusing to come back, I was left, with another of the guests, to amuse ourselves for three hours as best we could. What was to be done? It was ten minutes' walk to the town, and to the town we went. Here was a fine old church, recently restored; but it was locked, of course, and both of us were afraid of Bedels. "Was there a billiard-table?" we inquired of the postman. "No, but there was a bagatelle-board at the 'Cock and Trumpet,'" an alternative which did not allure us. So to the chief hotel for luncheon, though we had scarcely breakfasted two hours ago; and here we imbibed some fearful sherry, the which, I verily believe, is lurking in my system now. A cigar; and we seemed entirely forlorn and prostrate; when suddenly my thoughts emerged from their gloominess, like railway-carriages from a tunnel into sunshine.

"Are there any nursery gardens in the neighbourhood?" I inquired of the waiter, just bringing us, with the best intention, a copy of the *Times*, which we had read two days ago.

"Oh yes, sir," he responded to my great refreshment; "Budd & Packe's, sir; late Twig, sir. Anybody will show you the way, sir."

Away I sped, my companion following reluctantly, for he was no horticulturist, and having referred to "anybody" in the person of an intelligent baker, we soon reached the gardens; and in five minutes I was perfectly at home and happy in the congenial society of Messrs. Budd & Packe. We sauntered through the houses; we peeped into the frames; we wandered among squares of ever-verdant trees, phalanxes of flowering shrubs, and regiments of the deciduous order. We admired, we denounced, we compared. "Had I seen so and so?" "Did they grow what d'ye call it?" Did I know thingembob? I seemed to have been there but ten minutes, when my fellow traveller, first attracting my attention with a groan, whispered the information that he "was slightly sick of those confounded sticks, and, if he could, find a tank or pool, he thought he should go and drown himself." To which I murmured, "Au Reservoir;" and we parted. The hopeless Hottentot! Those confounded sticks" were the cleanest, strongest, straightest lot of briars I ever saw in my life, tall standards, and breaking beautifully; and he groaned at them! Groaned at them, and when I returned to the station, with two large baskets of plants, pretended painful anxiety as to mental state, and entreated me to have an interview with Doctor Conolly.

But never, since that day, have I been in want of occupation—never since have I suffered that loneliness, the solitude of a strange city, when have enforced a temporary sojourn in the noⁿ nursery garden. With principals, or, in foremen, I have fifty topics of mutual i-

every garden something new to see; from every gardener something new to learn; and so the hours pass swiftly, pleasantly, and I hope wisely, onward.

Wisely, I believe. For, after all, my brothers, it is the wisdom and goodness of gardening which make it such a deep and enduring happiness. It is thankfulness, reverence, and love, which make our gardens dear to us from childhood to old age, for,—

"Love is like the ocean, ever fresh and strong,
Which, the world surrounding, keeps it green and young."

Yes, it is because we cannot really love the beautiful flowers without loving Him "Whose breath perfumes them, and Whose pencil paints;" it is because there lies deep in the heart of a man a yearning to recover Paradise, and to rest once more upon the Mount of God; it is because when we cherish tenderly, and watch adoringly, the Creator's handiwork, that we are permitted to "walk with Him through the Garden of Creation;" it is because the life of a gardener is, or ought to be, a religious life,—

"Yea, holy is the gardener's life, for unto him is given
To be a fellow-worker with the sun and showers of heaven,
Gently to aid the labours of the feeming mother earth.

And watch and cherish tenderly her children from their birth;"

it is because the wisest of men, such as were Bacon and Newton, were happiest in their gardens, and spake of gardening, from a glad experience, as "the purest of human pleasures;" it is because men, such as was Wordsworth, have bequeathed to us the certain confidence that "Nature never did betray the heart that loved her;" it is for these reasons, and many another as true and gracious, that the pleasures of gardening are so great and lasting, and that of the earnest faithful gardener it may be justly said,—

"Thy thoughts and feelings shall not die,
Nor leave thee when old age is nigh
A melancholy slave;
But an old age, serene and bright,
And lovely as a Lapland night,
Shall lead thee to thy grave."

Thoughts like these ensured a special welcome for the Reverend Francis Goodhart, our Curate, as he entered our room of assembly. We were glad to have our Pastor's sympathy, and to appoint a Chaplain to our little band. Moreover, we ever found in him a cheerful companion and an enthusiastic gardener. You may see ample evidence of the latter characteristic in and about his cottage home; in his delightful garden, which seems to contain everything in miniature—a diminutive greenhouse, a small bed of American plants, a little rockery, a wee fernery, a tiny fountain, an intricate geometrical design on the most reduced of scales. Pretty creepers twining about his porch stoop to welcome you on your arrival, and the Jasmine and the climbing Rose look at you lovingly through the windows as you take your seat within. Passing through the hall—lobby would be more truthful, perhaps—you see, generally, a large bowl of wild flowers, gathered and admirably grouped by the children of the village school. In the study and drawing-room are choicer bouquets, either culled from his own Lilliputian conservatory, or offerings from some brother Spade, and arranged, as only ladies can arrange them, by his beautiful sister, Rose Goodhart, who shares and gladdens the Curate's home. At early morn, in the sweet summer-tide, you may see him, with his scythe in his hand, sweeping down the dewy grass, until the church bells call him to his daily service ("the wust and incurablest form o' Popery," according to Mrs. Verjuice), and he goes through the quiet graveyard, carefully honoured now, and ornamented with flower and shrub, and through the "ancel-door, by which the Rose "Felicité Perpetuelle" climbs "verward in emblematic beauty, into the hallowed courts of "ear old church. These, too, sometimes are reverently "by our Curate and his little band of acolytes, and "the "daughter is all glorious within" upon her greater "flower and branch, just as under the Older Test-

"in substance and no more in type, the chapters "the pomegranates, "and upon the top of the "ark." I like to see the children (but don't "ng the long ropes, covered round" with

evergreens, from their schoolroom, to festoon the arches, and encircle the pillars; and yet more do I delight to watch them hurrying home from wood, and bank, and brook, with their pretty posies in their hands. It pleases me most to see the fresh spring flowers at Easter, the bunches of Primroses and Violets smiling at intervals upon the dark green Yew; but those children tell me, and this of course, that the old church is most beautiful upon their own festival, the which, being held upon St. Luke's Day, brings Dahlias in clothes-baskets to our Curate, until the glowing glass in our painted-windows begins to pale its ineffectual fire, and our frivolous damsels to complain on Sunday that their best bonnets have not fair play.

Our Curate is not only a lover of flowers himself but a zealous missionary florist. He was instrumental in establishing our Cottage-Gardening Society, which has reclaimed many a waste place from the weeds, many a sot from the beerhouse, and brought comfort to many a home. I remember Tom Cooper's garden, for instance, as the favoured residence of every known British weed, and as the favoured residence also of the ugliest and leanest pig in the parish. Mr. Cooper devoted his spare time, at that period, to swearing, thick ale, and skittles, and, lightly esteeming a vegetable diet, quite ignored the science of horticulture. Somehow the Curate got hold of Tom, by giving him work, I think ("just like them Jesuites," Mrs. V. remarked), when he was nearly starving, and as lean as the pig which he had been compelled to sell, and then talked him into his "sober senses." And now, no labourer about the place has a cleaner, neater, bit of ground than Tom. Dock and Groundsel, Thistle and Twitch, which once grew as closely together as the bristles of his neglected beard, have been displaced for Lapstone Kidneys and Cottager's Kale, for Gooseberry trees and Currant trees, for the Peony, the Sweet William, and the Rose. It does one good to see Tom, when the daylight lengthens, digging and hoeing, sowing and setting; while Tom, junior, proudly holding a brown-paper packet of seeds, scowls at small Jacky for running between fayther's legs; and mother, with her baby at the cottage door, looks on with a thankful heart. And you would have been pleased, I am sure, if, at our last horticultural exhibition, you had seen, as I saw, the Curate, with his hand on Tom's shoulder, congratulating him on the prizes he had won. S. R. H.

(To be continued.)

THE HOUSEHOLD.

SALADS.

EVERY household in which a thrifty housewife presides boasts of some mysterious preparation with which the mistress of the house compels reluctant housemaids to rub the furniture at stated periods. The object of this operation is to keep the polish bright, and I believe it answers the purpose very well. I could not give the recipe of this wonderful compound, for I do not know it, but I could not better describe it than by saying that, in appearance, smell, and adventure taste also, it closely resembles that other mysterious compound which will be produced in a pyramidal and circumvoluted bottle if you ask for salad dressing at an hotel or an eating-house. Of course, no one in his senses expects to get anything particularly good to eat or drink at such places; but in private houses, where sometimes a good dinner is to be had, the same oddly-shaped bottle is the only source whence the salad dressing is obtained. Now the great charm of a good salad is, that not only the green meat part of it shall be fresh and newly gathered, but that the dressing or sauce shall be also fresh and newly mixed. The art, however, of mixing a salad dressing is all but unknown in this country. The operation entails too much trouble, and requires too great a nicety in the apportionment of the condiments, for the broad mind of the British cook to be troubled about it. Ask her to mix a salad, she simply pours out a good allowance of the contents of the queer shaped bottle over a lot of lettuce, endive, and watercress chopped up more or less small, and there you are. And yet salads are appreciated by Britons.

Hear what an English wit and divine—Sydney Smith, I think—says of salads:—

"Oh, great and glorious and herbaceous treat!
'Twould tempt the dying anchoret to eat.
Back to the world he'd turn his weary soul,
And plunge his fingers in the salad bowl!"

But my object is neither to prove that salads are very good things, nor that English cooks do not know how to prepare them. Few will

venture to deny either of these propositions. My purpose is to expound the art and mystery of dressing salads, and I shall leave it to the intelligent reader who will put my precepts in practice to decide whether a salad is a good thing; if he has any doubt on the point.

MATERIALS.

The consideration of salads may be divided under three heads—the vegetable part, or foundation; the dressing, or sauce; and the accessories. One of the chief requisites of a good salad is that it should be newly gathered, and, if you can get it free from mould and gravel, it is better not to wash it at all; but, as is more often the case, if you must wash your salad, you cannot be too careful in draining all the water from it, for every drop of water left in a salad tends to spoil it, no matter what amount of talent has been bestowed upon the dressing of it. Great care is also necessary in picking the salad, so as to exclude every leaf that is the least tainted or discoloured. It is a great mistake to cut up lettuces and endives, *more Anglico*, into fine threads. This operation at once destroys the freshness, taste, and character of the dish. Of course, I do not mean that coslettuces simply split in two should be made into a salad; but there is a happy medium, which is always best in most things. Besides, it is by no means the largest lettuces which make the best salads. The cos lettuce, which we call Roman lettuce, is all very well in its way; but the cabbage lettuce, the *laitue pommeée*, when it is well *pommée*, is by far preferable. This should be cut into quarters like an orange, and no more.

Endives can better bear cutting up than lettuces, and may be treated accordingly; but it is a mistake to put endives and lettuces in the same salad bowl. What is called corn salad goes better with endives, although I think that it is wrong to put too many herbs into one salad as a salad; as a condiment it is a different matter. As such, watercress, tarragon, burnet, garden (not what is called mustard and cress), American, and Australian cress, chervil, parsley, basil, mint, balm, marjoram, &c., may be used, but they must be used with discretion. Likewise beetroot, cucumber, onions, celery, radishes, potatoes, chives, garlic, can be put into a salad with success, if you know how to use them.

That overgrown herb (mustard and cress) which is always associated with all salads by the British greengrocer, should never be used if it can be avoided. The American and Australian curled and perennial cress are much preferable in point of taste and appearance. These, as well as watercress, tarragon and burnet, must not be cut up too small, but the leaves only, especially in the case of watercress, must be used, and not the stalks as well. They must be well washed, and the water may be got rid of by pressing them in a cloth, without injury to the freshness of the salad. Other herbs must be minced quite fine, and a pinch or two will be about the proportion of them for an ordinary salad. Chives and onions must be minced small also; but in some special cases, hereafter to be referred to, onions in slices are used; otherwise spring onions are the thing. Garlic is only to be used with an endive salad, and according to the taste of the probable partakers the proportion of it must be regulated. It need not, however, appear in the salad at all; a crust of bread slightly rubbed with it will convey a sufficient amount of flavour if it is put into the bowl only while the operation of turning the salad is going on. By a similar contrivance, a slight flavour of onion may be given to a lettuce salad. Celery chopped up small may be used as a condiment; or it may of itself form the staple of the salad. Potatoes make a very good salad (boiled, of course) of themselves, or associated with celery, beetroot, and other things; but they are also used as part of the sauce sometimes. Slices of cucumber are never amiss in certain salads. Radishes, whole or sliced, and slices of beetroot, help the ornamentation, if not the taste, of a green salad.

Another sort of salad is what the French call *Barbe de Capucin*. It is a blanched chicory, but the common endives are preferable. Dandelion, especially if it be cultivated, makes very good salad, either alone or with lettuces. The leaves and flowers of mallow and nasturtium, as condiments as well as ornament, are often put into and upon a salad with advantage. In Italy and the south of France they have a way of making a salad with unripe tomatoes, gathered just as they begin to show the least red. I cannot call to mind at the moment any other green meat which is eaten as a salad, but I may say generally that any vegetable which is not positively unwholesome uncooked can form the foundation of a salad. I have eaten delicious salads in Italy composed entirely of dandelions and other wild herbs gathered by the road and the river side. There is no lack of dandelions in the rural lanes of this country, and I believe burnet grows wild; but I should be puzzled to find the dozen and more different herbs which composed my wild salads, and I have not sufficient confidence in my botanical knowledge to try the experiment. Potatoes and beetroot are by no means the only vegetables which can

be made into a salad when cooked. Dried or fresh haricot beans, French beans, asparagus, Jerusalem artichokes, cauliflower, broccoli sprouts, turnip tops, &c., make very good salads. They should be plainly boiled in salt and water, well drained, and when quite cold make your salad.

(To be continued.)

THE FAIRY-RING CHAMPIGNON.

In our account of this (see p. 333) the references to the woodcut were unfortunately omitted; we therefore reproduce our illustration for the purpose of supplying them, in order to make clear the difference between the true champignon and its ally.—

Fig. 1. *Marasmius oreades* (Fairy-ring Champignon). Pastures, roadsides, and downs, in the autumn; colour, pale buff; gills, broad and far apart; diameter, 1 to 2 inches.

Fig. 2. *Marasmius urens* (False Champignon). Woods and pastures in the autumn; colour, pale buff; gills, narrow and crowded together; diameter, $\frac{1}{2}$ inch to 1 $\frac{1}{2}$ inches. This is poisonous.

NOTES AND QUESTIONS ON THE HOUSEHOLD.

Why should Potatoes be Steamed in Preference to Boiling Them?—Because potatoes, being a mass of flour-particles, become watery from being covered with a weight of water, the particles not being able to expand and burst into flour. With steam they are not covered; but if steamed too long the flour-particles absorb the steam, and become water-logged, but, of course, they are not such a watery mass as when they are boiled. Baked or roasted potatoes, if cooked too much, absorb steam, and become unwholesome. When potatoes are boiled, they should be covered with boiling water and a little salt; when they have boiled for five minutes, the whole of the water should be strained away, then be covered with cold water, and this also strained away, then about three tablespoonsfuls be put in the bottom of the sauceman, and the potatoes allowed to simmer slowly till they are done; then the cover of the sauceman taken off for the steam to escape. They are best if, the moment they are done, the sauceman is turned upside down with the cover on, and then the latter taken off when the sauceman is turned to its right place.

Sauerkraut.—To make sauerkraut, the cabbage is sliced by means of a knife fixed in a frame, and is something like an inverted plane. A clean barrel is lined with cabbage leaves on the bottom and a short distance up the sides. A layer of three inches of cut cabbage is put in and pressed down by the hand, and sprinkled with four tablespoonsfuls of salt. Four layers are put in in this way, and then the whole is packed down hard with a wooden pounder. Four more layers follow, with another pounding, and so on until the barrel is full. Cover with cabbage leaves, and put on a board follower with a heavy weight, and set away to ferment. Remove the scum at the end of three weeks, and, if necessary, add water enough to keep the kraut covered.

Currant Tomato.—I have grown this as a pillar fruiting plant, on trellises for ornament, and for the first time it has been used in autumn in many ways by our *chef de cuisine*. I have a notion that it could be used as a winter fruit preserved in sugar syrup, as it does with all of ripe fruit, as elegantly by the French. It would form a very beautiful if the colour, and the entire grape could be preserved. The name allude to is the *Solanum racemigerum*, which must not be confounded with a variety sometimes called the currant, of the size of a cherry. It is as small as a black currant, and with grappes a foot and more. H. K., in "Gardeners' Chronicle."

The Marsh Marigold as "Spring Greens."—Among our indigenous plants used as greens, none is so generally employed—at least in the Eastern States—as the marsh marigold (*Caltha palustris*), perhaps for the reason that in its localities it grows abundantly, and is readily gathered. In April and May, the wet meadows and the margins of Brooks are made gay by the golden buds and flowers of this plant. The leaves are round-heart-shaped, and of rich green. The flowers look much like large buttercups; indeed, the plant belongs to the same family as the buttercup or crowfoot. The leaves and tender stems are gathered at or just before flowering time. The plant when fresh is considerably acrid, but this quality is removed by cooking. In most localities the plant is known as "cowslips." It is unfortunate that the early settlers should have applied this name, as the plant has neither resemblance to, nor relationship with, the cowslip. It is a native of England also, and there it has for hundreds of years been called marsh marigold, although it is not a marigold.—*American Agriculturist.*

THE FRUIT GARDEN.

PEARS IN THE CHANNEL ISLANDS.

MR. BAINES says (p. 298) that the French and Channel Island pears are not superior in flavour to those grown in England. Pray pardon me if I say that I cannot allow our grand old Duchesses and Charenteles to be so underrated. I have seen and grown these pears in different parts of England, and I must say that I have never found them equal, either in size or flavour, to those grown in France or in the Channel Islands. Let me speak first of the Charenteles. Many years ago, when my father was gardener to the late Sir Robert Newman, Bart., Mamhead Park, near Exeter, he planted fourteen trees of the Charentelle in the gardens there, twelve of which were grown and trained as low flat table trees about eighteen inches off the ground, much in the same way as our modern ground cordons are grown. The two other trees were grown and trained against brick walls; the one on an east, the other on a west aspect. All these trees, both table trained and on walls, produced, during most seasons, plentiful crops of fruit; as much fruit, indeed, as I have ever seen produced by similar trees in Guernsey. In appearance those on walls were the finest; but as regards flavour they were worthless for dessert, being hard and gritty as a baking pear; and indeed this was the only use that was made of them. I may add, too, that few pears beat Charenteles for baking or stewing. I knew a Charentelle tree grown against a south wall near Taunton; also another very large tree on a south-east wall near Lyme Regis, in Dorset, and one at Fulham Palace, to all of which the same remarks apply. With these trees I was acquainted for years, and never once did I see a first-class fruit, either for size or flavour, in any way approaching the Charenteles grown in the Channel Islands, where they are rich, sugary, melting, and as juicy as a peach. This I would attribute not so much to the heat of our summer, as to its length, compared with the summer in England. Having grown numerous varieties of pears under glass, both early and late sorts, I have come to the conclusion that late hanging and late keeping pears are much improved in flavour by being grown under glass. I was thus enabled to let them hang longer on the trees in autumn, and when they came to maturity, say in March, April, and May, the improvement in flavour was very striking compared with fruit that had ripened on walls or pyramids in the open air. I have observed, too, that these indoor fruits keep better; they do not shrivel so much, having been guarded from the inclemency of the weather. They are also kept safe from birds, which spoil much of our best fruits when left on trees late in autumn in the open air. I have not much to say in favour of cultivating early pears under glass, as they do not ripen much earlier than they would outside, unless a high temperature is maintained, when the flavour will be found worthless; but if kept cool, as they should be, with a constant current of air passing through the house at all times, then I say many of our early blooming pears, as well as many of our first-class shy-setting pears, may be grown under glass in the greatest perfection.

Apples under glass I have had but little experience with, only having cultivated a few small trees of Ribston Pippin; these I must say were fine both in flavour and appearance, but I keep the house very cool, with constant air in it.

Rohais Nursery, Guernsey.

JOHN RICHARD WILLIS.

A NEW ENGLANDER ON THE GOOSEBERRY.

From the time when I read of Mistress Doctor Primrose's gooseberry pie, which the Doctor celebrates in his charming autobiography, I entertained a kindly regard for that fruit. But my efforts to it successfully have been sadly baffled. The English climate, I think, will bring it to perfection. I know not how many res I have made with Roaring Lion, Brown Bob, Conquerors,

and other stupendous varieties; but without infinite care, after the first crop, the mildew will catch and taint them. Our native varieties—such, for instance, as the Houghton Seedling, make a better show, and with ordinary care can be fruited well for a succession of seasons. But it is not, after all, the staunch old English berry, which pants for the fat English gardens, for the scent of hawthorn, and for the lowering, fog banks of Lancashire. Garden associations (with those who entertain them) inevitably have English colouring. Is it strange—when so many old gardens are blooming through so many old books we know? No fruit is so thoroughly English in its associations; and I never see a plump Roaring Lion but I think of a burly John Bull, with waistcoat strained over him like the bursting skin of his gooseberry, and muttering defiance to all the world. There is, too, another point of resemblance; the fruit is liable to take the mildew when removed from British soil, just as John gets the blues, and wraps himself in a veil of his own foggy humours, whenever he goes abroad. My experience suggests that this capricious fruit be planted under the shadow of a north wall, in soil compact and deep; it should be thoroughly enriched, pruned severely, watered abundantly, and mulched (if possible), with kelp, fresh from the sea shore. These conditions and appliances may give a clear check even to the Conquering Hero. But it is not so much for any piquancy of flavour that I prize the fruit, as because its English blight is pleasantly suggestive of little tartlets smothered in clotted cream eaten long ago under the lee of Dartmoor Hills—or Lancashire gardens, where prize berries reposed on little scaffolding, or swam in porcelain saucers—and of bristling thickets in Cowper's "Wilderness," by Olney. Is it lonely in my garden of a summer's evening? Have the little patterning feet gone their ways—to bed? Then I people the gooseberry alley with old Doctor Primrose, and his daughters Sophia and Olivia; Squire Burchell comes, and sits upon the bench with me under the arbour, as I smoke my pipe. How shall we measure our indebtedness to such pleasant books, that people our solitude so many years after they are written! Oliver Goldsmith, I thank you! Crown Bob I thank you! Gooseberries, like the English, are rather indigestible.—*Ik. Marvel.*

THE SNOW APPLE OF CANADA.

WHAT a delightful little apple is the Pomme de Neige, and yet how very seldom do we see it! It is a very old acquaintance of mine. I knew it, and loved it for its intense beauty and excellent qualities, long before I learned its correct name. It is an apple that succeeds well in northern situations. I have seen it in admirable condition on Deeside, Aberdeen; and it is stated, in the *Transactions of the Horticultural Society*, by Sir George Steuart Mackenzie to succeed well in Ross-shire. The fruit is rather above medium size, ovate-conical, very regularly formed, the eye closed, the stalk nearly an inch long, the skin greenish-white on the shaded side, brilliant scarlet, streaked with brilliant scarlet on the sunny side; at all times exceedingly beautiful. The flesh is pure white—white as snow—peculiarly tender, juicy, melting, and pleasantly flavoured. In season from October to Christmas. This is in every respect a most interesting apple, and altogether distinct from the ordinary class. The brilliant scarlet skin, in contrast with the pure white flesh, renders it strikingly beautiful; and the texture of the flesh is of that peculiarly tender character which many of the American apples possess, such as we find in the Melon, Northern Spy, and partly in the French Calville Blanche—firm yet short, and melting in the mouth, like Scotch short bread. The Snow Apple was, I believe, introduced from Canada by Mr. Barclay, of Brompton, under the name of La Fameuse, which is given as a synonym in the *Fruit Catalogue of the Horticultural Society*. I have not been able to distinguish it from another apple named Pomme Lückken, in the collection of the Horticultural Society; but I cannot answer for the Pomme Lückken being correct. The name Pomme de Neige signifies the Snow Apple, being significant of the whiteness of its flesh; this is not, however, the source whence it was derived, but from the name of a village where it is much cultivated (see *Horticultural Society's Transactions*, vii. p. 334). I would strongly recommend the re-establishment of this truly beautiful, very interesting, and altogether excellent apple in our gardens.—A. F. Barron, in "Florist and Pomologist."

A WILD FRUIT GARDEN.

WRITING this tangle-wood, I have set a few graftlings upon a wild crab, and planted a peach or two—only to watch the struggle which these artificial people will make with their wild neighbours. And so various is the growth within this limited belt, that my children pick there, in their seasons, luscious dewberries, bucklerberries, wild raspberries, bilberries, and choke-cherries; and in autumn gather bouquets of Golden-rod and Aster, set off with crimson tufts of

Sunach, and the scarlet of maple boughs. And when I see the brilliancy of these, and smack the delicate flavour of the wild fruit, it makes me doubt if our progress is, after all, as grand as it should be, or as we vainly believe it to be; and (to renew my parallel) it seems to me that the old-time and gone-by thinkers may possibly have given us as piquant, and marrowy suggestions upon whatever subject of human knowledge they touched, as the hothouse philosophers of to-day. I never open, of a Sunday afternoon, upon the yellowed pages of Jeremy Taylor, but his flavour and affluence, and homely wealth of allusions, suggest the tangled wild of the garden with its starry flowers, its piquant berries, its scorn of human rulings, its unkempt vigour, its boughs and tendrils stretching heavenward; and I never water a reluctant hill of yellowed cucumbers, and coax it with all manner of concentrated fertilizers into bearing, but I think of the elegant education of the dapper Dr. ——, and of the sappy and flavourless results.—*My Farm of Edgewood.*

POT CULTURE OF THE TOMATO.

Those who wish to stand well with the cook, will find a weekly supply of a dozen or so of Tomatoes throughout April, May, and June, go far to secure that position. In autumn I have found the wires on which I have grown my melons useful to suspend my Tomatoes on to ripen. Any decayed ones which happen to drop I allow to remain on the hard melon soil. The seeds from these, owing to the genial warmth of the house (which is here appropriated after melons to stove plants during the winter), soon vegetate, and the soil being hard, the plants cannot root deeply in it; on the contrary, they spread on the surface, thereby inducing shorter-jointedness, and thus rendering the plants better suited for pot culture. When six inches in height they are potted three in a pint pot and plunged in the warmest part of the house, where they grow rapidly.

In the early spring I repeat on ten-inch pots, using a compost of turfy loam, sand, and thoroughly decayed leaf-mould or old mushroom-bed dung, in equal parts; and place them where they may obtain all the sun and light possible, a point of much importance, as otherwise they become weak and useless; but a few days elapse before they show signs of renewed growth, and before allowing them to get too tall I put sticks to each plant nearly upright and almost close to the rim of the pot. As soon as they have fairly commenced growth, I water them freely with liquid manure, not too strong nor at all times, as sunlight is as yet too feeble to warrant too free a use of this stimulant. From this time the plants grow fast, and require attention in the way of tying and removing useless wood—not by entirely removing it, but by timely stopping it so as to induce greater vigour in the shoots from which the first and finest fruit is to be obtained. When the plants are in bloom it is well to gently draw the flowers through the hand daily, an operation which assists their chances of setting. I do not consider it judicious to administer stimulants to any fruit-bearing plants in bloom, believing them to be at that time rather injurious than beneficial. As soon as sufficient fruit is set I carefully remove about an inch of the surface soil and fill up with turfy loam and bones, which greatly aid the swelling fruit, and I recommend the use of liquid manure, which may be employed stronger than hitherto, the Tomato, like the Vine, being a gross feeder.

Under this treatment I have been generally able to obtain on an average from two to three dozen fruit from each plant, the side shoots which I stop producing an abundant crop in succession. B. O.

A CAROL OF SEED-TIME.

SUGGESTED BY ONE OF WALT WHITMAN'S.

A song of the glad seed-time;
A song of the soil and the flying March dust;
A song no more of winter's icy breath;
A song of the dry lea field; [tassels;
A song of the smell of burnt woods and of the larches' green
A song tasting of chives and watercresses.

For the balmy breath of spring and for Nature's gladness,
Now I return to see the daisies springing.
Reclining on thy breast, Oh! Mother Earth,
I feel the throb of thy sun-warmed pulse,
And turn a verse for thee.

Oh, earth that teems with richness when well till'd!
Oh, ploughs and harrows; and bright tickling hoes!
Oh, merry ploughmen turning up the sods!
Oh, lusty laborers sowing or drilling corn!
A verse to notice and to praise you all.

—WILLIAM TILLEY, Welbeck Gardens.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Asparagus Culture of the Ancients.—Having read somewhere that the culture of asparagus by the ancients differed but little from our present practice, I should be glad if any of your readers would inform me what the published instructions for its culture really were.—R.

Horseradish.—If Mr. Watson (p. 340) grows his horseradish on a heavy yellow soil he will not obtain the length he wishes to get it. He is right in saying that horseradish does not increase in length in a downward direction after it is planted. As to planting in March, I have never done so in that month. The reason why I choose November for planting is, because I have found that my young plants have become established by the end of February. Horseradish is troublesome to keep within bounds. I grow mine at the end of one of the best quarters of the kitchen garden, where it is bound in by walks on three sides of the bed. Last November I put in plants twenty-four inches long.—THURSTON SOUTHWORTH, Castle Head Grange, Lancashire.

Big Vegetables.—It is a common mistake of inexperienced people to consider size as the most important of all qualities, alike in flowers, fruits, and vegetables. Within certain limits, size is undoubtedly of importance, but the instant we favour size at the expense of colour or flavour in vegetables or fruit we encourage retrogression. Good flavour, tenderness, and beauty of appearance are three most important qualities and should be sought in preference to size, although, as remarked above, when certain limitations are recognised, every advance in the size of any particular vegetable is an advantage. In any and every case quality should be sought for first, and, as a rule, of two sorts equal in quality, the largest must have the preference. This subject is to be considered in connection with cultivating as well as in the purchase of seeds. The ambition to grow large cucumbers causes many an amateur to cut for his table, or his friends, coarse fruits of great size that are simply tough, bitter, and unwholesome, instead of smaller fruits of tender texture and delicious flavour and perfect unwholesomeness. Nearly all the vegetable marrows in cultivation are too large. The largest beetroot are much more suitable for the pig trough than the salad bowl. We have frequently advised the cultivation of the smallest in preference to the largest sorts of cabbage, because of their delicacy of flavour. The largest onions are the worst keepers.

Native Guano Company.—A question of some public importance was discussed the other day at a meeting of the Metropolitan Board of Works. Twelve months ago the Native Guano Company, which proposed to employ sewage in the manufacture of manure by what is known as the A B C process, applied to the Board for permission to erect works near the southern outfall of the main drainage system at Crossness. On the representation that the company would use 500,000 gallons of sewage, or thereabouts, daily, permission was granted by the Board—the company undertaking to erect its works within three months. This has not been done, and it has been deemed desirable that steps should be taken to make the company carry out its experiment at once, for at present an impression is abroad which is entirely without foundation that the A B C process is somehow under the patronage of the Board. It is necessary therefore to state that, by allowing the company to erect works at Crossness, the Board merely intended to sanction an interesting experiment—the delay in the trial of which is to be deprecated—and had no intention whatever of expressing an opinion favourable or otherwise on the plan.

RUSTIC WORK.

In keeping with their effect, I caused gates to be constructed of the simplest material, from the cedar thickets; varying these in design, and yet making each so simple as to admit of easy imitation and to unite strength, solidity, and cheapness. If, indeed, these latter qualities could not be united, the work would not at all meet the end I had in view—which was not merely to produce a pretty effect, but to demonstrate the harmony of such decorative work with true farm economy. One often sees, indeed, rustic work of most cumbersome and portentous dimensions overlaid with extraordinary crooks and curves, and showing at a glance immense labour in selection and in arrangement. All this may be pleasing; and often exceedingly beautiful; but it is a mere affectation of rural simplicity if it wears none of that fit and simple character which would at once commend it to the eye of a practical man as an available and imitable feature. If I can give such arrangement to simple boughs, otherwise worthless, or to pine-pickets of simple cost—in the paling of a yard, or the tracing of a gate, as shall catch the eye by its graceful outline, and suggest imitation by its easy construction and feasibility, there is some hope of leading country tastes in that direction.—D. G. Mitchell.

THE man who has nothing to boast of but his illustration like a potato—the only good belonging to him is under Overbury.

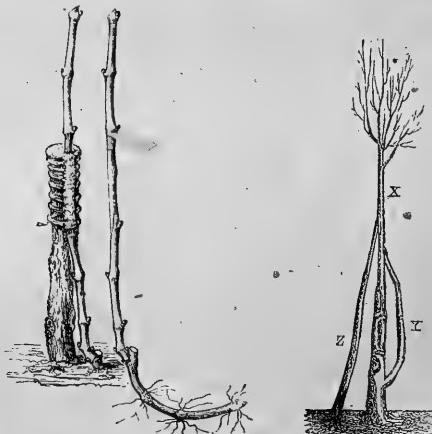

THE PROPAGATOR.

THE ART OF GRAFTING.

(Continued from page 336.)

GRAFTING BY APPROACH APPLIED TO THE RESTORING OF PLANTS. This is not the only method in use for the restoration of defective plants, but it is a valuable one when the object is to change the variety of the tree, to renew its stem, or to repair the want or loss of branches. Of each of these cases we give an example:—

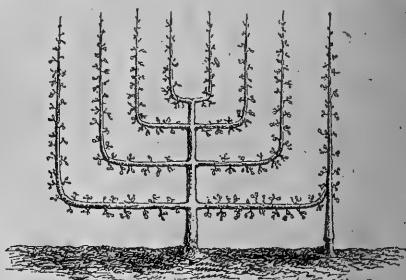

1.—CHANGING THE VARIETY.—The Vine is restored in this way. Alongside the stock which it is desired to change to another variety, is planted in winter a young vine well rooted and furnished with a thoroughly ripened shoot. When the time for grafting arrives, in April, the stock is cut down according to the height of the new plant, and as low as possible. With the curved gouge, a longitudinal groove is made in the top of the stock, into which is laid the shoot of the young plant, slightly pared on the sides. It is then cut down to two or three eyes above the graft; after it has been bandaged and covered with grafting-wax. Instead of shortening the stock at once, it might be left until the graft has been perfectly united and shortened in the following spring.

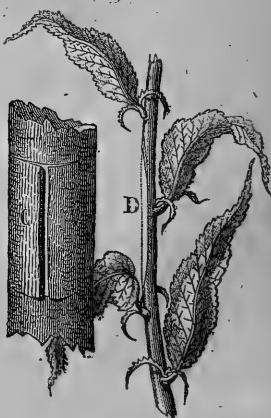

2.—RENEWING THE STEM.—The subject (X) whose stem is cankered and which has "gourmand" branches at the base can be repaired by means of these branches (Y) being inarched upon the stem above the diseased part. The flow of the sap, which has been interrupted by this, will thus be re-established. Should the diseased tree have no branches at the base, a stout stock is planted near it. After a year's good growth, the head of the stock (Z) is cut off and inarched into the stem of the other above the canker. Should a single tree not be sufficient for this restoration, a number are planted round and grafted into the old one in the same way, and when the graft is thoroughly established the cankered base may be cut away.

3.—RESTORATION OF MAIN BRANCHES.—In the training of fruit trees to any particular form there will sometimes be gaps or vacancies when certain parts have not been able to develop themselves, or have disappeared. If a branch cannot be obtained by close pruning, incision, branch or bud τ , the neighbouring branches are made use of and in such a manner that the symmetry of the design is deranged. But as the branches do not always furnish sufficiently vigorous for this purpose, a speedy curing the partial loss of a branch is shown in

the annexed illustration. Here a deficiency on one side of a chandelier palmette is supplied by planting a young tree near it into which the defective branch is grafted. It should be of the same or a similar kind as the old tree in habit and vigour; and if the grafting is effected by inarching it should not be done for at least a year after the planting of the young tree.

4.—FURNISHING BARE BRANCHES.—On trees of a certain age it is difficult to obtain, either by means of incision or bud or branch grafting, fruiting branches on those parts which want them. It will be necessary then to employ the method of grafting by approach, that is if the vacant places are near suitable branches. The Peach tree, which is liable to lose its branches, usually bears shoots which can be easily grafted by approach on the bare spots, and the operation is performed in June and July with herbaceous shoots. A vacancy exists which it is desirable to supply with a branch. In the beginning of summer the herbaceous shoot is taken and applied to the branch, where it is grafted by approach. The shoot is cut opposite to an eye which is let into the incision in the branch, and the extremity will go on to develop itself. The result will be a good fruiting branch when the detachment takes place,

at least a year afterwards. Instead of making an incision in the main branch, it will be sufficient to raise the bark by a double T incision if the condition of the sap allows it. In this is placed the shoot, which has been slightly cut at D, opposite an eye. The development of this shoot will facilitate the fork pruning used with the fruit branches of the Peach. This method was recommended in 1829 by M.

Leroy, gardener at Auteuil. Inarching is useful for furnishing branches with shoots. An eye or a shoot may be grafted or budded into the bare part. Sometimes we make use in August of grafts which were inserted in the month of June preceding. If there is no anticipative branch, one is excited to develop itself by pinching the shoot three weeks before grafting. When the young branch is developed, the leaf which springs from its base is partially pinched, in order to force the fruit buds of the new branch to continue at the base. The pruning of the fruiting branch will be afterwards made easier by this operation. The Vine is easily furnished with shoots on vacant parts by approach grafting. It is best to employ herbaceous shoots in May or June. The bark only of the stock should be cut, without removing any of the wood, especially if it is old; in which case, or when the scion is woody and not herbaceous, the detachment is effected by degrees in two years. In 1868 we applied successfully to the Vine this method of inarching in order to fill up

vacant spaces on the stems. The shoot, headed and pared under an eye, was let into the stem by a \perp incision. (A month afterwards the union was complete, and the bud (A) grew vigorously. This was the first time, we believe, in which this mode of grafting was used with the Vine.

To PRESERVE THE FORM OF THE TREE.—When the advantages of approach grafting are better appreciated, it will be more frequently used for preserving symmetry of form and equilibrium of growth in trees trained in particular forms and shapes, and will also simplify the labour of pruning, pinching, and tying up. We saw in the Horticultural Society's Garden at Mulhouse, a fine wall of Peach trees in an oblique cordon, joined at the top by approach grafting. The heat of the sun and the gout had injured some of them so much that M. Menet (professor of gardening to the society) had been obliged to cut away the damaged stems to the height of three and a quarter feet and burn them. The upper parts were left, and these continued to live and bear fruit, being fed by the sap of the neighbouring trees, on which the shoots had been grafted by approach. Horizontal cordons of Apple trees present the same result when the stems of any trees which have been grafted into the adjacent ones are cut away.—*C. Balle's "l'Art de Greffer."*

(To be continued.)

OBITUARY.

MR. THOMAS INGRAM.

WE have to record, with great regret, the death of Mr. Thomas Ingram, late of the Royal Gardens, Frogmore, who died at Upton Lodge, Slough, on the 9th instant, at the age of seventy-six. It is only a few years since Mr. Ingram left the scene of his more active duties at Frogmore, and retired to enjoy a well earned but not coveted rest, at a quiet house at Slough, within sight of the Royal towers of Windsor. Losing the stimulus which the obligation of work to be done always gives, parting with his long-watched and cherished trees, his seedling fruits and flowers, and the many treasured things that haunt a home—the bright spot signalled by the labours and successes of a long life—he drooped and faded, and quietly and resignedly breathed his life away.

Mr. Ingram was the son of a nurseryman, and was trained with Mackintosh and other eminent men in that great school of gardening of fifty years ago, the nurseries of Messrs. Lee, of Hammersmith. He was engaged by her Majesty Queen Charlotte to superintend the Royal Gardens at Frogmore in 1816, and remained at Frogmore until

1833, when King William IV. gave him the direction of the whole of the Royal Gardens at Windsor. Early in the reign of our present Queen the ancient and widely scattered gardens were given up, and one grand central forcing and kitchen garden was formed on the Royal estate, on a spot immediately contiguous to the Frogmore pleasure-grounds; this garden, thirty-two acres in extent, was formed, planted, and brought to that high state of perfection that has so long distinguished it by Mr. Ingram.

After the passing of the Windsor Improvement Act in 1849, the arrangements for laying out and constructing the new walks and drives in and about the Home Park, the Castle Grounds, and Frogmore were entrusted to Mr. Ingram, and the narrow and shady walks of the slopes were replaced by bold open roads, whose free sweeps and curves, stretching away towards Frogmore, are well seen from the terrace of the Castle. One of the last labours of Mr. Ingram was the re-arrangement of the pleasure-grounds at Frogmore, rendered necessary by the erection of the Mausoleum within the gardens, the last resting-place of the illustrious Prince Consort, with whom Mr. Ingram was associated in many works of improvement about the Royal estates.

During his long life Mr. Ingram devoted himself assiduously and with unflagging interest to the task of originating new and improved varieties of fruits, flowers, and vegetables, and by careful selection and hybridization he was successful in adding some useful examples to our list of fruits and beautiful flowers. Among fruits the Frogmore Scarlet-fleshed Molon is still highly esteemed. The British Queen, Frogmore Swan's Egg, and Golden Russet Pears are valuable contributions to our list of English fruits. The Frogmore Orleans, Bonne Bouche, and large late Greengage plums have merits which will make them generally appreciated. The Frogmore Bigarreau, F. Early Black, and F. Morello Cherries are each improvements on sorts of recognized value. No fewer than nine new strawberries rewarded Mr. Ingram's attention to that excellent fruit, among which, the Frogmore Late Pine, Prince of Wales, Mr. Radcliffe, may be taken as examples. Three apricots, each having special recommendations for precocity, size, and late-keeping properties, prove that this fruit was not neglected. The Frogmore Golden and Premier peaches were also raised at the Royal Gardens.

The old scarlet Pelargonium known as the Frogmore Scarlet was obtained in 1817; and one of the very first double Dahlias about the same time. Two hybrid Begonias, an Epacris, Lonicera, and Escallonia attest Mr. Ingram's attention to our valued garden flowers; while an excellent broccoli, the Frogmore Protecting, and a hardy cucumber, show that vegetables were not forgotten.

Mr. Ingram was fortunate enough in the course of his long connection with the Royal establishment to secure the approbation of the Sovereigns he served so faithfully; and a just appreciation of his services to horticulture was exhibited by a large number of friends joining in a subscription to a handsome testimonial, which was presented to him a few years before he left the Royal Gardens.

He was much respected by all the members of the Royal Family, and has been frequently visited by her Majesty since his retirement from active life; even as late as Friday week, the day before his death, the Queen is said to have paid him a visit. Kind and genial in disposition he was esteemed by all who knew him, a man indeed for whom everybody had a good word; he therefore leaves a wide circle to lament his loss.

MR. WILLIAM OSBORN.

ONLY a week or two ago it was our sad duty to record the death of Mr. Thomas Osborn, and now we have to announce that of his elder brother and co-worker, Mr. William Osborn, which took place early on the 7th instant. The firm of Osborn & Son is one of the oldest in the neighbourhood of London, and has been for many years worthily represented by these two brothers, who were respected by all who knew them, or had business dealings with them. Osborn gardeners ever found friends able and ready to help them when assistance was most required; their towards all was kind and gentlemanly; and to the world generally their too early deaths is a sad loss.

OUR WEEKLY CALENDAR

PRIVATE GARDENS.

Conservatories, Greenhouses, &c.—These are brilliant with gay flowers, which the bright weather now experiencing brings forward with so much rapidity. Grandifolius and Wallachii, together with Odontoglossums, Lycastes, and other orchids at present form objects in the way of plants for conservatory decoration of all kinds now receive strict attention with tying, and training, and they are allowed plenty

elevating them above the ordinary level of their associates on inverted pots. Azaleas and Camellias in flower are shaded a little from bright sunshine. Such as have done flowering are placed in an intermediate temperature and encouraged to make growth. Greenhouse hard-wooded plants are being potted, as are also palms that will succeed in a greenhouse temperature. In most cases stove plants have now been potted, and with the assistance of an increased temperature, and plenty of moisture at the root, overhead, and in the atmosphere, they have commenced their summer campaign under favourable circumstances. Give a little air in the mornings during fine weather, but shut up early. Syringe freely such plants as Palms, Dracaenas, Marantas, Anthuriums, &c. Early Gloxinias are now in flower, and others are ready to succeed them. Orchids are receiving a gradual increase of heat and moisture.

Indoor Fruit Department.—Pines are now being cut in good condition, others are swelling, flowering, and coming on in succession. Those ripening receive little water, whilst those in a less advanced state are more liberally supplied with it. To suckers a temperature of 65° at night is given, these farther advanced are allowed 70° , with a rise of 10° by means of sun heat. The bottom heat is kept at about from 75° to 80° . Some give weak manure water at the root, and also sprinkle the plunging material and paths with it; others only use water. Late Vines are allowed abundance of air, so as to keep their buds back. Vines just started are kept close and freely syringed; thinning both bunches and shoots also receives attention. Where borders are artificially heated, care is taken that they do not become too dry. Figs: these now receive plenty of water overhead, as well as at the root. The farthest advanced have a night temperature of 60° . The second house has now the same temperature as the first; the third one is kept at 55° at night, allowing a rise of 10° by sun heat. Peaches, Nectarines, Apricots, and other fruits are well syringed, except when in flower, and due attention is paid to thinning of fruit.

Hardy Fruit and Kitchen Garden Departments.—The grafting of fruit trees has now commenced, more especially in the case of stone fruits. Fruit trees on walls are being protected. Pruning generally is finished, and the ground between lines of trees and bushes manured and dug. Potatoes are still being planted. Carrots, Parsnips, Beetroot, &c., are being sown in some places, whilst in others main crops will not be sown for a few weeks yet. Turnips are being sown. Autumn-sown Onions are being transplanted. Lettuces are being sown for succession, and others planted out when the weather is damp, or failing that in the afternoons. Sowings of Radishes are made according to demand. Sowings of Broccoli, Savoys, Brussels Sprouts, Kale, and Cabbages are made for early use. Cabbages are being planted out.

NURSERIES.

Indoor Department.—The general repotting of stove and greenhouse plants, in most cases is now all but finished, but there are always extra things that require shifting regularly according to their respective wants. Anthuriums, Marantas, tropical Palms, and many other stove plants now enjoy a brisk moist temperature. Nepenthes have been repotted in loose material, such as sphagnum and very fibrous peat. Draconas and Diefenbachias are being propagated from pieces of the roots and stems, inserted in cacao-nut fibre, or similar material, in a brisk heat. Seedling Palms are being potted singly. Plants of Bonapartea juncea raised from seed are also being potted off singly in small pots. Aralias that have been taken from pieces of the root, and that are now pushing a few leaves, are being potted off into their propagating pans and potted separately, as raised from seed are being pricked off into pans, or potted into thumb-pots. Various kinds of bedding and sub-tropical kept in strong heat in order that they may furnish cuttings. Cuttings are also being sown.

• Department.—Though a bad season for transplanting numbers of them still continue to be lifted, and supply vious plants are being re-arranged in lines. Grafting more especially Cherries, is being proceeded with. it were budded last year are now headed back to four inches of the buds. Cuttings of Privet are hickly in lines about a foot apart. Gooseberry cut-
o be put in, as do also suckers from stone fruits, the are trimmed, and the points of the shoots cut off; ed for stocks. Layering of Rhododendrons, Limes, 'bus, continues to be done, and those well-rooted from are separated from the stocks, and planted in lines bacous plants are being divided, and replanted
igated by cuttings. Clematises and other hardy
d, & vaceous on sheltered borders.

MARKET GARDENS

Born fruit and vegetable crops appear to be more forward than usual. Rhubarb is now obtained in large quantities from the open ground. Some growers, however, still cover their Rhubarb with litter, which, they say, keeps the stalks cleaner and of better quality than when exposed. Asparagus beds continue to be earthed up; young Asparagus, in many cases, has pushed a few inches through the ground; supplies are still cut daily from the forcing beds. Forced Seakale is plentiful. Potatoes are being planted extensively; in some cases, they are put in as digging progresses—in others they are dibbled in, and in some instances they are ploughed in. Lettuces continue to be planted out, and Cos and others are sown for succession. Lime is thrown over these plantations, to prevent the attacks of slugs and snails. Cauliflowers are planted in shallow drills; drawn between every two lines of autumn-planted Cabbage, which are about to be removed. Autumn-sown red and other, Cabbages are being planted out on well-manured ground. Spent seed beds, where these have been growing, are heavily manured and prepared for other kinds of produce. Early sowings of Cabbages and other greens are now being made, and White Globe Turnips are being sown extensively. Spinach is sown largely broadcast, and between lines of bushes, &c.

SOCIETIES. EXHIBITIONS, &c.

ROYAL BOTANIC SOCIETY, REGENT'S PARK

The first spring show of the season held by this Society took place on Wednesday last. The weather was delightful, and the display of flowering plants very satisfactory. One of the principal features was the Stagedumbell, which were truly grand. Messrs. Veitch & Sons, Chelsea, staged superb collections of these charming flowers, which deservedly won the first prize. Mr. Wm. Paul also showed a good collection; nor did room from amateurs stand far behind them in point of quality. Mr. A. Douglas, gardener to F. Whittington, Esq., Loxford Hall, Ilford, came a collection of Tulips, pleasingly varied in regard to color, and altogether excellent. Messrs. Veitch & Sons also furnished a beautiful exhibition of the same showy flower. Mr. Weir took a first prize in the amateurs' class, which was also well supported by Messrs. Rowe and Stephenson. Chinese Primulas were in good condition, Mr. Wm. Paul producing some fine plants of Waltham White.

Cyclamens were also exhibited in lovely condition. Mr. Wiggins, of Isleworth, had a collection in which we noticed a charming pure white form, a bristly variety of *Persicaria*, of good habit and faultless form. What would Cyclamen-growers forty years ago have given to have been able to produce such plants as those which Mr. Wiggins showed on Wednesday last? There is, however, this to be said in their favour: they had no such glass accommodation for their growth as we have now. There were, likewise, some very fine pots of Lily of the Valley from Messrs. Rollinson. Mr. Ward, gardener to F. G. Wilkins, Esq., showed a few interesting Orchids, amongst which we noticed well-flowered specimens of *Odontoglossum triumphans* and others, a capitally-bloomed plant of *Phaius grandifolius*, and two beautiful varieties of *Lycaste Skinneri*. Mr. Ward also took a first prize for Heaths—finely flowered plants, but not large. There were likewise some pretty little Azaleas, and a very creditable collection of Rhododendrons in pots from Messrs. Lane & Son, of Berkhamsted. Roses, both in pots and in the shape of cut-blooms, were present in excellent condition, the three great Rose-growers, Mr. W. Paul, Messrs. Paul & Son, and Messrs. Lane, each contributing excellent collections. Camellias in pots were, for the most part, small.

Mr. S. Ware, of Totteham, contributed a good collection of small scutellates and hardy spring-flowering plants. Amongst the latter were the exquisite Primula, rivals, Dog's-tooth and other Violets, Orobous vernus, the Siberian Squill, Adonis vernalis, Heartsease, many Heathas, Hepaticas, and others, together with prettily variegated Pinks, Hemes, rockeas, and a pan of Lily of the Valley with variegated foliage.

Hardy Orchids in pots, gems with which everybody is familiar, were shown by Mr. Needie, gardener to the Comte de Fair at Twickenham. Among them were *Ophrys apifera*, *O. speciosa*, *O. tenthredinifera*, *O. tricolor*, *O. boucambura*, *O. lutea*, *O. apiculata*, *O. fusca*, and *O. lutea*. *Orchis longicornis*. Hitherto these most interesting plants have always been considered to belong to the province of the botanic garden; but, however, we have never seen them successfully grown. Mr. Needie has, however, shown that they can be as successfully cultivated as a common crocus-plant or hardy bulb.

as any common greenhouse plant.

Among the new plants from Messrs. Veitch, Rollisson, and Williams, the following received certificates—viz., *Veitchia canterburyana*, Kentia australis, *K. Forsteriana*, from Messrs. Veitch and Williams; also *Agave Seemannii*, *Toxicophila Thunbergii*, *Tillandsia Lindenii*, and *Davallia Tyra manii*, from the latter exhibitor. Mr. Ley had also a certificate for the last-mentioned plant under the name of *Humata Tyramina*. *Martinezia erosa* and *Calamus verticillaris* from Messrs. Rollisson also received certificates. To Mr. William Pant, floral certificates were given for *Yuccinia* Lord Mayo, violet plum with a white throat, very distinct and pretty; and *Ornement des Roses*, with large pale blush buds, faintly streaked with rose down the centre of each petal. *Reine de Naples*, bright rose striped with carmine, was pleasing in colour. A certificate was likewise awarded to Mr. Reed, Twickenham Ait, for *Polyanthus Princess of Wales*.

GARDEN

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

THE FLOWER GARDEN.

SPRING TREATMENT OF BEDDING PLANTS.

The time will soon be at hand when people begin to turn their half-hardy plants out of doors, to make room for others still tenderer and younger. Many grow a large stock for summer work in pots, and it is when these are exposed to drying spring winds that the stock suffers. For this reason, roughly-knocked-together boxes are more useful than pots, as their mass of soil prevents the roots from being alternately roasted and chilled, like those in little pots; the boxes are also much easier watered, and retain moisture longer than pots. The consequence is, the plants in boxes do not acquire that stunted and miserable aspect which some people take for "hardening off" and are in a much better condition to fill the beds when planting-out time has arrived, the healthy roots striking out at once into the soil. Again, long confinement in small pots causes masses of roots to form on the outside of each ball, which must either be ruthlessly broken off at planting time, to the injury of the plant for the time being, or it will take the roots much longer to find food in the new soil. It is evident, then, that those who grow in boxes have little to fear in this respect. They may, however, run a risk in exposing the plants to cold cutting winds at a too early date, and thus injure them, or they may not give them that gradual hardening off and exposure which insure that the plants once placed in the beds will not suffer from any ordinary check.

In the case of those cultivating largely in pots there is, moreover, a better practice than that of leaving the established stock in small pots all through the spring months; it is to turn them out into temporary pits or frames, in very light, easily worked soil, breaking the balls slightly in the case of those that are pot-bound. If a lot of those excellent and economical turf pits be placed near the flower garden, this system will prove a great advantage. The plants will root in such as if in the open air, and, transferred carefully to the flower garden on some moist day, when all danger is gone, will not suffer the least check, while they will present that fully feathered and dwarf growth which things treated on the starving system only assume after being several weeks in the open air. Some recommend shading them during the middle of the day in such positions; but, except for a day or two after planting, we should certainly injure them to the full sun from earliest spring, always taking care to keep them moist and in a congenial root medium, and thus, while securing them a warmth for which they are always grateful, prevent any check from strong sun at planting-out time. In many cases, instead of potting singly strong, well-rooted cuttings, it would be much better to plant them out at once in such pits in spring.

Another advantage gained in thus planting out in pits and frames is that numbers of pots may thus be emptied and used for other purposes. Usually in spring there are more of these wanted than can be obtained. And the same objections do not apply to the pots filled in spring as to those filled in autumn, as the feeding roots have not time to exhaust the soil in the former, and then compress themselves into a dense

mat around the sides, the very position in which they are most liable to meet with hurtful vicissitudes. In the case of things potted late in spring, the young roots are just coming to the sides of the pot when planting-out time arrives, and are therefore just in a condition to root straight into the soil in which they are placed. There are some few things, too, to which life in a single pot is agreeable—succulents for example; but generally the box and planting-out system should be adopted.

Nothing is so good as low turf pits, nothing so easily made in a country place; and even where rough turf cannot be had, they may be built of stiff earth. We need not repeat that if these pits could be arranged near the flower garden or scene of final planting out it would be a great advantage, inasmuch as all subjects planted out in pits should be carefully taken up with a trowel and transferred immediately to the beds assigned them, no lying about being permitted, as is the case with plants in pots. As for the rough boxes, they may be brought alongside the beds and their contents planted at pleasure. In small places the difficulty of carriage from pits to beds is not noticeable, but in large ones, with the glass houses a long way from the flower garden or pleasure ground, it may become a serious matter. If the turned-out plants have to be carried a long way to the beds, the balls should be packed closely together, so as to prevent rapid evaporation, and covered with a shade of some kind while in transit.

As for protection in the pits in spring, it should vary according to the plant; in the case of pretty hardy things like the verbena and calceolaria, much may be done by the use of tarpaulin stretched on light frames, and only used at night, except in severe weather; glass, on the other hand, will be required for the geranium race until the late spring arrives. Strong calico, stretched at a foot or so over the plants, does very well for some things, and may be left on all day, admitting light enough. Countless things will do with mere night protection by means of any light covering rolled over them, and not a few of the hardy breed, now beginning to have much seed, need no protection whatever once spring has fairly set in—the new bedding violets for example. Care must, of course, be taken not to bring a hardy plant, struck and raised in a warm temperature, into the cold at once. Raise a dock or a nettle in a warm propagating house, or hotbed, place it for a night in the open air, and it will perish in a few hours. It will suffer as much from cold as a native of some warm latitude. Should circumstances not permit of the plants in small pots being planted out in cheap pits and frames, as we suggest, every means should be taken to preserve them from being injured from lack of water, exposure to dry cold winds, or checks of any kind. T.

THE VINE AS A HARDY ORNAMENTAL PLANT.

JUSTICE has rarely been done to the Vine as a mere object of beauty. We have grown it for its fruit, and while looking intent for that have well nigh overlooked its high claims as a decorative plant. Even in this age of fine foliage plants, when we are in so danger of hiding up our flowers in a thick forest of leaves, the leaves of the Vine are comparatively neglected, or, if sought after, they are more used as a garniture for desserts than for any purpose. And yet, for covering vacant spaces on walls, for roof trees, festooning pillars inside of houses, or covering roof spaces with verdure, or clothing bald places outside few plants can equal, perhaps none excel, the Grape.

The form of its leaves from first to last is exquisite colours most lovely. Who shall describe the softness of the young Vine leaf bursting from its infant bed? During its progress it is painted by turns tint of green, and then, when the change comes over how varied and how beautiful are its changing hues! bud at its base gives the old leaf notice to quit incessant knockings and pokings, the leaves of the more beautiful. Feeling the tenure of the short, they resolve to weave for themselves a, they depart to be no more seen.

Some Vine leaves, it is true, put on a dull russet when they die; but others, such as the Barbarossa, and, last and best of all, the Claret, clothe the gorgeous robes as the sun of their life before Like the sun himself, who paints the clo

before he sinks beneath the horizon, so those Vines clothe themselves in all the glories of the rainbow before they fall. Talk about fine foliage, what foliage can equal a West's St. Peter's Vine, with its inimitable mixture of crimson, green, and sometimes gold? And the Claret Vine, with the sun playing hide-and-seek among its fluttering leaves, is a sight that can scarcely be equalled among plants. It will match the finest Virginian Creeper that was ever seen; and more can hardly be said in the praise of any ornamental plant.

The Vine is worthy of being planted in all vacant spaces for its leaves alone. Their colour and form are most beautiful. The latter varies more than many would suppose. From the wide expanse of a White Nicae, measuring a foot and a half across, big enough almost for a baby's parasol, we come down to the exquisitely-cut and delicate Parsley-leaved Vine, and the tiny variegated one of our gardens. The word garden reminds me that the Vine would furnish a better green than many other plants employed to train round our flower beds. It would make green frames for glowing colours, such as would cool the eyes of our friend "S. R. H." without the help of the famous Parsley; and no plant could be better suited for scrambling over sunny rocks, clothing uncouth blocks, and climbing loosely over rustic poles, than the Grape Vine. Its freedom of growth, the curious beauty and strong grasping power of its tendrils, its inherent grace, its subtropical associations, are all points of the greatest merit in an ornamental point of view.

For these purposes it will likewise be found perfectly hardy throughout the greater part of Great Britain and Ireland. Even if thrown to the ground, it will, under good management, spring killed up again in twenty or thirty feet in one season. With up and make a rod such an amount of growing energy all things a plant endowed with should the clusters of fruit show and swell are possible. And then has thoroughly described their beauty? and ripen, who can, when neither is it needful that the Vine should The thing is impossible. As a source of interest and beauty in climb like a giant to become annuals, strong stools would furnish gardens. If treated almost as of our highly-prized subtropical a forest of shoots, excelling in interest than such a variety as plants. Few plants are more roots and leaves, powdered with Miller's Burgundy, with its stout stems and periwigs. This forms a white dust, like our great-grandfather's strawberry-leaved Vines. I hear, grand contrast to the Claret and Strawberries much more gorgeous in too, that some of the American varieties are colouring and varied in form than our cultivated sorts, and I trust our growers will see to providing a stock of them. The Vine has another rare merit as an ornamental plant: no plant—not even the violet, sweetbrier, lime—can rival the sweetness of its blossom. It would add a fresh fragrance to our gardens and pleasure-grounds. It can hardly be needless to add more. In most large places thousands of vine buds are sacrificed annually. All these are plants in embryo that might clothe or sweeten much in need of both.

As seen in vineeries, our formal modes of training rob the Vine of most of its grace and elegance. But fancy rows of pillars, or series of arches, or fronts of houses and walls, or masses of rocks, or even beds of flowers, wreathed round, interlaced or encircled with Grape leaves, such as the Claret, in all their autumnal glory, and the glossy black clusters of Grapes looking out invitingly among them! and many other plants will hide their heads in modest shame as they hasten to crown the Grape Vine king over the ornamental plants in our gardens.

If the Grape be generally planted as an ornamental plant, albeit many will not only be astonished at its beauty, but more will be gratified to find that it will yield fruit well worth the in the most unexpected localities. D. T.

UNDA REGALIS AND FERN COLLECTORS.

e handsomest of our British Ferns, once grew abundantly in Sussex and Hampshire, but under the ruthless collector, it is fast disappearing. From one situated Portsmouth Road, where ten years back it grew not entirely gone, having been torn up and loaded to Covent Garden Market. Indeed, so Fern-collecting rage becoming to our native plants as the Green Spleenwort (*Asplenium viride*) and late Ferns of Derbyshire are rarely met with so plentiful, and local botanists wisely conceal their precise habitats, as, if once known, their immediately extirpated. The Osmunda is a garden, but it is generally placed, with the stony soils, in dry or rocky situations, whereas er plant, loving wet, boggy places. We never than in a garden in Herefordshire, at the edge close to a pond, with its roots quite in the "bloom" and its fine tuft of leaves, it

F. P.

ROSE SEC.

I CAN, perhaps, put your correspondence roses as readily as verbenas, if not as freely, as we are generally some pot roses forced in most gardens, and after flowering every eye will make a plant. In this case cuttings are put in from February until the middle of April, that it is too hot for them, and frequently after March is uncertain, unless put in a north propagating house and kept as possible. The system adopted is to thin out all the required, and to shorten in any straggling growth, or to cut off pricks, for convenience of handling, and cut the shoots into single eyes, prick them out thickly into a cutting bed, on a bottom heat of 70°. Nearly every cutting will be rooted in three weeks. They are potted into two-inch pots, placed in a warm house for a short time, then into a cool one, and hardened off like other plants, and planted out in rich ground; they make nice plants, either for planting in beds or potting by the autumn. Another plan is, to take all the straggling shoots from roses in November; cut them into lengths with three or four eyes, and dibble them thickly under lights or head-glasses under a north wall. A large proportion will root in the spring; one light will contain several thousand cuttings. Roses on their own roots are far the best, especially in this climate, where the briar will not succeed. In England, eyes of unripe wood will root in a partially exhausted hotbed all through the summer, but will require keeping in a frame until the next spring. I have propagated hundreds in this way.

JAMES LAPIN.

South Amboy, New Jersey, U.S.

SALVIA PATENS.

FIFTY strong plants of this beautiful blue sage put out in a line made a grand display here all the latter part of last summer, and if they had been fringed along with a row of scarlet and rose-coloured Penstemons, the effect would have been heightened. This charming Salvia is not half as much grown as it deserves to be; but the fault does not so much rest with the plants as with those who coddle and otherwise maltreat them. After the blooming season is over, the tuberous roots should be lifted, and carefully stored for the winter in a dry place; but when, for purposes of propagation, renewed growth is demanded, ten chances to one the roots will be found dead. I grew my stock last year to secure seed, and from one thousand to twelve hundred seeds was no crop from fifty plants, certainly, but I hope to have five hundred plants this year. Without a particle of bottom heat, I can, this, the 28th of February, take up one hundred cuttings for a start, and could continue to do the same weekly until my wants are satisfied. When shifting my Salvia roots at the end of October last, I at once planted them out thickly together in a soil bed in a greenhouse, just keeping the mould moderately moist through the winter.

Before Christmas the roots had begun to throw up young growth, but this I found, as soon as it reached the surface, was so injured, as to prevent further growth. Although not certain, still I believe this was caused by woodlice, and, to make matters secure, I gave the roots a top dressing of half-an-inch of sawdust. Through this the young growth is coming like a thicket of green, and I do not find one root unequal to its duty. Since the sawdust dressing not a shoot has been touched, and, if I had plenty of bottom heat, I believe I could convert my fifty plants into five thousand by May with comparative ease.

A. D.

NOBLE ORNAMENT.

ALL ornament is base which takes for its subject human work: it is utterly base—painful to every rightly-toned mind, without perhaps immediate sense of the reason, but for a reason palpable enough when we do think of it. For to carve our own work, and set it up for admiration, is a miserable self-complacency, a contentment in our own wretched doings, when we might have been looking at God's doings. And all noble ornament is the exact reverse of this. It is the expression of man's delight in God's work. For observe, the function of ornament is to make you happy. Now in what are you rightly happy? Not in thinking of what you have done yourself; not in your own pride; not your own birth; not in your own being, or your own will, but in looking at God, watching what He does; what He is; and obeying His law, and yielding yourself to His will. You are to be made happy by ornaments; therefore they must be the expression of all this. Not copies of your own handiwork; not boastings of your own grandeur; not heraldries; not king's arms, nor any creature's arms, but God's arm, seen in His work. Not manifestation of your delight in your own laws, or your own liberties, or your own

inventions; but in divine laws—constant, daily, common laws;—not Composite laws, nor Doric laws, nor laws of the five orders, but of the Ten Commandments. Then the proper material of ornament will be whatever God has created; and its proper treatment that which seems in accordance with or symbolic of His laws. And, for materials, we shall therefore have, first, the abstract lines which are most frequent in nature; and then, from lower to higher, the whole range of systematised inorganic and organic forms.—*Ruskin.*

ARUNDO DONAX IN THE PLEASURE GROUND.

This great reed of the south of Europe is a very noble plant on good soils. In the south of England it forms canes ten feet high, and has a very distinct and striking aspect; it will grow higher than that if put in a rich deep soil in a favoured locality; and those who so plant clumps of it on the turf in their pleasure grounds will not be disappointed at the result. Nothing can be finer than the aspect of this plant when allowed to spread out into a mass on the turf of the flower garden or pleasure ground, as many may have seen it at Sion. It seems much to prefer deep sandy soils to heavy ones; indeed we have known it refuse to grow on heavy clay soil and flourish most luxuriantly on a deep sandy loam in the same district. Like all large-leaved plants, it loves shelter. No garden or pleasure ground in the southern parts of England and Ireland should be without a tuft of it in a sheltered spot. But, fine as it is for effect and distinctness, its variegated variety is of more value for the flower garden proper.

The variegated variety of *A. Donax* (*A. D. versicolor*) will be found perfectly hardy in the southern counties, and considerably north of London, may be saved by a little mound of cocoanut-fibre, sifted coal-ashes, or any like material that may be at hand. In consequence of its effective variegation, it never assumes a large development, like the green or normal form of the species, but keeps dwarf, and yet thoroughly graceful. It is of course best suited for warm, free, and good soils, and abhors clay, though it is quite possible to grow it, even on that with a little attention to the preparation of the ground. But it is in all cases better to avoid things that will not grow freely and gracefully on whatever soil we may have to deal with; and it is to those having gardens on good sandy soils, and in the warmer parts of England, that we would specially recommend this grand variegated subject. For a centre to a circular bed nothing can surpass it in the summer and autumn flower garden, while numerous other charming effects may be afforded by it. Not the least happy of these would be to plant a tuft of it on the green turf, in a warm spot, near a group of choice shrubs, to help, with many other things named, to fill the gap that is now nearly everywhere observed between ordinary fleeting flowers and the taller tree and shrub vegetation. It is better to leave the plant in the ground, in a permanent position, than to take it up annually. Protect the roots in the winter, whether it be planted in the middle of a flower-bed or by itself in a little circle on the grass. It is easily increased by placing a shoot or stem in a tank of water, when little plants with roots will soon start from every joint; they should be cut off, potted, and placed in frames, where they will soon become healthy young plants.

The Great Reed (*Arundo Donax*), associated with Conifers, &c., in the Pleasure Ground.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Lost Crocuses.—Since the death of Dean Herbert, whose useful work on Bulbous plants should be in everybody's hands, this beautiful genus has been sadly neglected and overlooked, many most lovely and easily-cultivated species have been lost, and others have become so rare, that it is next to impossible to get hold of them. There is no more lovely Crocus than that little gem *C. lacteus*, with its creamy white flowers, or its still more beautiful variety *penicillatus*, which has delicate veins of blue; but where are they to be had? Then, again, there is the pale sulphur-flowered *C. ochroleucus*, a denizen, I believe, of Lebanon, and the netted-rooted *C. reticulatus*, with its variety, *albicans*, the true "Cloth of Silver." Who will help me to reintroduce these belles of spring into our gardens? —H. HARPER CREWE, *The Rectory, Drayton Beauchamp, Tring.*

Large Norfolk Carex.—Mr. Gorrie, forester to the Earl of Leicester at Holkham Hall, sent some time ago some very large plants of *Carex paniculata* to the Edinburgh Botanic Gardens. The plants measured from the base of the roots to the extreme points of the leaves eight feet six inches. When so large, these Carexes bear some resemblance to the dwarf grass trees of Australia. Three men were required to lift each plant; they grew in rich moist and very deep peat, and are supposed to be a century old. Mr. Gorrie says:—"We have some taller and heavier plants than any of those sent. I observe they grow strongest when the roots get into the water.

I am told, where foxes abound, they are very fond of lying on the top of the Carex tufts and basking in the sun. This gigantic Carex is very common on sodden peaty soil in Norfolk."

Myosotis dissitiflora.—This charming spring flower has been in blossom since the 15th of February; indeed I noticed some sprays of it showing colour in the last week of January. As to hardiness I can only say that out of over two thousand bedded out there is not one dead or even sickly; they are all from seed of 1871, sown when gathered. I mention this as I have noticed division recommended in preference to seed. Of course this has been a mild winter; but we lie cold and damp on a strong clay, and damp has been considered the worst of the foes that assail this tiny gem.—R. C. Herts.

Calceolaria.—My stock of these is somewhat deficient. Can they be struck now with any chance of success? and what am I to do with some I have in boxes? What is a good substitute for the Calceolaria?—LYDIA. —[These may be struck now on a gentle hot-bed. Your autumn-struck plants, if growing freely, will furnish cuttings. Those wintered in boxes should have a cool frame prepared for them, in which they should be planted out about six inches apart. They require a deep, rich, loamy soil. The best substitute for the yellow Calceolaria is *Tatiges signata* *pumila*

Intermediate Stocks.—A hint or two as to the proper treatment of these will much oblige.—Z.—[A few of them, if required for early flowering, may now be sown in heat, and, as soon as fit to handle, pricked out into boxes or frames; they must be hardened off gradually, and may then be planted out in the end of April in well-prepared rich soil. For late summer and autumn flowering sow thinly under hand-glasses on a south border, and allow them to remain there until planted out in May, when they are to bloom; before planting out, the hand-glasses should be removed on all favourable occasions, so as to keep the plants dwarf and stocky.]

Daffodils.—The *Narcissus* of which I send you some blooms was found growing in a field near the Usk. It appears to be different from the common Daffodil, which is abundant in the neighbourhood, both as to the flower not being sessile in the sheath, the more regularly six-lobed crown, and also the greater length of the latter. Will you kindly say if it is more than a mere variety?—G. B.—[Your *Narcissus* is evidently a small variety of *Narcissus major*. It is identical in the colour of the petals and the trumpet, and totally different in this from any of the varieties of the common Daffodil. We shall be glad of a root or two. Please also to send your address: we have a communication for you.]

THE ARBORETUM.

GAME COVERTS AND ORNAMENTAL PLANTING.

The ordinary system of planting shrubs out in woods, to render shelter and protection to game, and to give ornamental effect, is frequently productive of unsatisfactory results. This has been attributed to various causes; but I venture to say that in nine cases out of ten the failure may be traced to a total neglect in the preparation of the ground, to carelessness in planting, and a want of proper protection and attention to the shrubs for a few years after planting out. The most judicious system of planting evergreen shrubs to effect the twofold object of game shelter and ornament is to plant each variety in groups or clumps of from ten to fifty plants in each, so as to vary the sizes of the groups, and from two feet to six feet apart from plant to plant. No definite rule can be laid down as to the particular distribution of these groups. They should, however, be placed at irregular distances apart, a few yards from the wood rides, round the margins of woods near public roads. A few large clumps should also be placed in any open space in the centre of the wood. Care should be taken as much as possible to avoid planting immediately under the spread of trees, as the encroachments from the roots of standing timber are very injurious to the healthy growth of shrubs, and light and air also are most necessary to their health. The planting of evergreens in groups or clumps is a great source of shelter and protection to game, especially during winter, when deciduous shrubs have shed their leaves, and when ferns and rank weeds are laid flat on the ground. Game of all kinds delight in small patches of evergreen shrubs, with plenty of open space round, and they detect a continuous mass of under-covert. The life and ornamental effect imparted to a wood by evergreens planted here and there in judiciously placed groups, fully compensates for the trouble and expense incurred, apart from the benefit to the preservation of game.

After the selection of the ground for the various groups, the first point to be attended to is to see that the ground is dry. If there is any stagnant water or superfluous moisture, open cuts or trenches should be made to drain it off; but the thorough preparation of the ground for the reception of the shrubs by turning the soil to a depth of from twelve to eighteen inches deep is the great secret of success, and the shrubs will start into growth and thrive all the better if a few barrow-loads of leaf mould, fibry turf well smashed up, or road drift be added and well incorporated with the original soil. Pits should be made for the reception of each plant large enough to admit the roots without the least bending or crumpling, and the roots should be carefully spread evenly round the pit, then the finest soil should be added till the pit is about two-thirds full; the plant should be kept straight and upright in its position, and the soil should be gently and evenly trodden round, and then more soil should be added round the plant till level with the rest of the ground, care being taken not to bury any of the lower branches.

The shrubs must next be protected from Master Banny's depredations, for the only shrubs that will entirely resist the nibbling and barking propensities of hares and rabbits are Rhododendron ponticum and Daphne ponticum and Laureola. Many shrubs are puffed up as distasteful to rabbits, but, with the exception of those mentioned, I have failed to find any that are proof against their attacks, as all extensive planters must know that when shrubs are newly planted out hares and rabbits quickly detect and punish severely any new introduction into the covert; therefore, if ground game abound, wire netting should be fixed round every group; it should not be more than $\frac{1}{2}$ -inch mesh, and not less than 4 feet 6 inches high, and be inserted in the ground 6 inches to prevent rabbits from working underneath. Many planters use wire netting from $\frac{1}{2}$ feet to 3 feet high; but I consider this too low, for hares can hop over it with the greatest ease, and I have seen a rabbit run up wire netting 3 feet high and get over, almost with the agility of a squirrel. All shrubs for the first two or three years after planting out should have the hoe kept going amongst them, to keep down rank weeds and grass; this will encourage the shrubs to start into growth quicker and thrive much better than they can if the ground is impoverished and light air excluded by a crop of weeds growing about them.

I will now endeavour to give a list of the best evergreen shrubs adapted for covert purposes, with a few remarks on each which experience and close observation have prompted.

Common laurel stands pre-eminent as a covert shrub, being a rapid grower of spreading habit; will bear any amount of cutting, is easily propagated by cuttings, and moderately cheap. This shrub is one of the best for extensive planting.

Portugal laurel, a beautiful shrub, affords a striking contrast to the former variety, for its foliage is a bright dark green, and its habit more compact; it is well worth planting out, affording as

it does variety and contrast, but it should not be exposed to cutting winds, as it is not nearly so hardy as the former.

Mahonia Aquifolium is a low, spreading, hardy, ornamental shrub, and bears an abundance of fruit which pheasants are very fond of. This shrub cannot be too highly recommended for planting out in coverts; it is easily propagated like hollies or thorns by sowing the fruit, and is consequently becoming cheap. Special care should be taken to keep the ground round this plant when newly planted out free from weeds and grass.

Privet, one of the most easily cultivated shrubs grown, and one of the fastest growers; it is cheap, very easy to shift, and not at all fastidious as to soil. There are, however, several varieties, and care should be taken in getting the true evergreen sort. It is unequalled as a quick growing covert shrub.

Rhododendron ponticum, a bold, vigorous growing, ornamental shrub, specially adapted for peaty ground, but will thrive in a great variety of soils. This shrub may be classed as excellent in an ornamental point of view. In regard to its qualities as a game shelter shrub, I do not believe it should be considered one of the best. When it gets fairly established and spreads, its lower branches grow too much in a tangled mass, and form anything but a comfortable bottom covert for pheasants, and I have observed that game do not run under rhododendrons so freely as under laurels, privet, yew, &c. &c. Its greatest recommendation is that it may be planted out where hares and rabbits abound, and never suffers at all from their attacks.

Common yew, one of the best shrubs grown, either for ornament or game shelter, is unsurpassed for planting in exposed situations; it is, however, a rather slow grower, and somewhat expensive; will thrive in any ordinary woodland soil.

Common holly, like the preceding, cannot be too extensively planted; it is unrivalled for beauty and hardiness, and will thrive well under the drip of trees. It is rather a difficult shrub to transplant; the latter end of April or beginning of May is the best time to shift it.

St John's Wort, a low-spreading shrub, unsurpassed as a dwarf covert plant, thrives best in a light, sandy, peaty soil. When planted out in small patches, its creeping stems will in a short time spread over a large space of ground. This shrub is seldom planted out for covert purposes; nevertheless it is one of the most useful grown.

Gaultheria Shallon, another of those useful dwarf shrubs of creeping habit seldom planted out to any extent in woods, notwithstanding its good qualities. This is one of the few shrubs found to thrive in fir and pine plantations; thrives best in a sandy, peaty soil; it bears fruit eagerly devoured by pheasants.

Berberis Darwinii, Wallichii, and japonica, Box, Aceruba japonica, Laurustinus, Photinia serrulata, Phillyrea, Arbutus, Euonymus japonicus, Rhamnus Alaternus, Ruscus aculeatus, Juniper (of sorts), Cotoneaster (of sorts), Kalmia latifolia, Privet (of sorts), and Garrya elliptica are all beautiful shrubs, and well adapted for giving shelter to game; should be planted out in groups near wood rides to give variety. In conclusion, with regard to the proper season for transplanting shrubs, I do not think so much depends on the time of year in which this is performed as on the state of the plants, the condition of the ground and the weather. As a rule the best time is autumn; but the planting of evergreens may go on till late in spring. Dull, cloudy days should be chosen; dry, windy, frosty weather should be avoided.—George Berry, Longleat, in "Field."

HARDY TREES AND SHRUBS.

THE SILVER BELL, OR SNOWDROP TREE (HALESIA TETRAPTERA.)

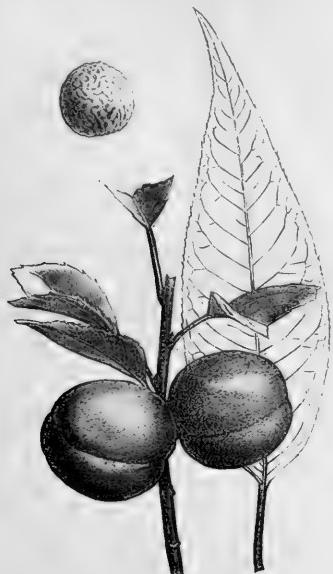

This is one of the most ornamental of all the American deciduous small trees which we possess, and richly deserves a place in every collection, on account of the profusion of Snowdrop-like blossoms which it produces in April and May. In this country it attains a height of from twenty to thirty feet, grows freely in any good garden soil, and in the climate of London, not only flowers freely, but ripens seed in abundance. It is a native of North Carolina, where it grows on the banks of rivers, and was first introduced in 1756; is easily increased by cutting the roots, or by means of seeds, which, however, often remain more than a year in the ground before they vegetate. The leaves are alternate, ovate-lanceolate, sharply serrated, and with the middle depressed and the footstalks glandular. The flowers are pure white, nine or ten together, in lateral fascicles, drooping, and in shape and size resemble those of the common Snowdrop. The corolla is monopetalous, ventricosely campanulate, with a deep four-lobed border. The

drupe or fruit is dry, corticate, and oblong, with four winged angles and cells one-seeded. For limited places or suburban gardens this is a very suitable little tree. G. GORDON, A.L.S.

NEW ORNAMENTAL PEACH.

(*PERSICA DAVIDIANA.*)

This is a new species of Peach of no value as a fruit tree, but likely to take a high place in the list of ornamental shrubs. It has been named after Père David, who sent some stones of it to the Museum about the year 1863, and is thus described in the *Révue Horticole*:—A vigorous shrub, with wide-spreading (sometimes weeping) branches; leaves glandular, on wide red stalks, regularly attenuated towards the base, with very fine short teeth not closely set; glands globular, small, few (wanting in most of the leaves), almost always solitary, and placed on the stalk or at the base of the leaf. Flowers of a delicate rose colour (in one variety white); numerous (of medium size, about three quarters of an inch in diameter), appearing before those of the Almond tree. Fruit small, a little over an inch in diameter, almost spherical, usually a little larger on one side, with a velvety skin, of a greyish colour, changing

New Ornamental Peach (*Persica Davidiana*).

to yellow when ripe, which occurs about the middle of August. It is perfectly tasteless, and has hardly even the odour of a Peach. M. Carrière describes this as an exceedingly handsome shrub, and differing so remarkably in habit from all Peaches hitherto known, that the most skilful Peach-grower would never take it for one of the family, particularly if he beheld it when deprived of its leaves.

MISTLETOE-BEARING OAKS.

The following instances of the mistletoe on the oak are given by Mr. James Britton, of the British Museum, in the *Field*. The first seven are given by Dr. Bull in his very interesting paper upon the subject published in 1864. The remainder have been still more recently noted:—

1. The oak at Eastnor, mentioned by Mr. Gordon.
2. The oak at Tedstone Delamere, Herefordshire, discovered in 1851. Mr. Lees states that there are two Mistletoe Oaks in this locality.
3. Oak at Badham's Court, Sudbury Park, near Chepstow.
4. Oak at Burningfold Farm, Dunsfold, Surrey.
5. Oak in Hackwood Park, near Basingstoke.
6. Oak not far from Plymouth, by the side of the South Devon Railway.

7. Oak at Frampton Severn, Gloucestershire.

8. Oak at Haven, in the ancient forest of Deerfold, Herefordshire, figured in the Transactions of the Woolhope Club for 1869.

9. Oak overhanging a double cromlech at Plas Newydd, Anglesey.

10. Oak at the Hendre, Llangattock Lingoed, Monmouthshire, discovered in the winter of 1870, and figured in the Woolhope Transactions for 1870-71.

11. Oak at Bredwardine, Herefordshire, discovered early in 1871; the parasite grows upon it in fifteen different places. A beautiful photograph of the tree is given in the volume of Transactions above referred to.

12. Oak near Knightwick Church, Worcestershire, discovered in 1871.

I have from time to time published, in *Notes and Queries* and the *Journal of Botany*, extracts from the older writers in which Mistletoe Oaks are mentioned; and there is in the Kew Herbarium a specimen labelled "from the Oak near Winchester."

With reference to the parasitism of the Mistletoe, the Rev. R. Blight publishes in the Woolhope Transactions a very valuable paper, illustrated by diagrams, which should be carefully consulted by anyone engaged in investigating the subject. The specimens from which the drawings were made have been presented by Mr. Blight to the botanical department of the British Museum, and are there exposed to view in the public room.

ORNAMENTAL PLANTING.

It is after all more in the disposition of the shrubbery, than in the varieties, that a rational pleasure will be found. It is not a great burden of bloom from any particular shrub that I aim at. I do not want to prove what it may do at its best, and singly; that is the office of the nurseryman, who has his sales to make. But I want to marry together great ranks of individual beauties, so that May flowers shall hardly be upon the wane when the blossoms of June shall flame over their heads; and June in its turn have hardly lost its miracles of colour when July shall commence its intermittent fires, and light up its trail of splendour around all the skirts of the shrubbery. I want to see the delicate white of the Clematis (*virginiana*) hanging its graceful festoons of August, here and there in the thickets that have lost their summer flowers; and after this I welcome the black berries of the Privet, or the brazen ones of the twining Bitter-sweet. Or, it is some larger group with which we deal—half up the hill-side, screening some ragged nursery of rocks—and a tall Lombardy Poplar lifts from its centre, while shining, yellowish Beeches group around it—crowding it, forcing all its leafy vigour (just where we wish it) into the topmost shoots; and amid the Beeches are dark spots of young Hemlocks—as if the shadow of a cloud lay just there, and the sun shone on all the rest; and among the Hemlocks, and reaching in jagged bays above and below them, are Sumachs (so beautiful, and yet so scorned), lifting out from all the tossing sea of leaves their solid flame-jets of fiery crimson berries. Skirting these, and shining under the dip of a Willow, are the glossy Kalminias, which at midsummer were a sheet of blossom; and the hem of the group is stitched in at last with purple Phloxes and gorgeous Golden-rods. I know no limit indeed to the combinations which a man may not effect who has an eye for colour and a heart for the light labour of the culture. There is, unfortunately, a certain stereotyped way of limiting these shrubberies to a few graceful exotics, and of rating the value of foliage by its cost in the nursery. It is but a narrow and ungrateful way of dealing with the bounties of Providence.—*My Farm of Edgewood*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Pruning Conifers.—I have a *Picea Nordmanniana* in which the leader has not grown six inches during these last two years. Will you inform me how the pruning of the side branches, as recommended by Mr. M'Nab, should be done? Should the wood be cut back? and if so, how far? or would it be sufficient to rub off the buds at the extremities of the branches? Lastly, should all the branches be pruned?—A SUBSCRIBER, [Mr. M'Nab, to whom your query has been submitted, says you will have to wait till August, when all the side branches of your plant may be freely cut, so as to give it a pyramidal shape. As you have not given the height nor the diameter of your tree, it is impossible to say exactly how much ought to be cut off. If the plant is small, you should cut the branches by putting the knife below them, and cutting upwards and outwards; and if large, the upper branches, or those above the eye line, should be cut by putting the knife above, and cutting downwards and outwards—the intermediate ones being straight. After the points have been taken off the main branches, whether it be one, two, or three feet, the side branches should also be shortened. After being cut, cover the surface of the ground below the branches with some good soil. The plant will be disfigured for a year or so, but it will soon recover, and the leader rapidly increase.]

Shrubs and Flowers which Thrive under the Drip of Trees.—As many of our readers are likely to take an interest in these, we enumerate a few, and shall be much obliged to anybody who will add to them:—

Laurus nobilis	Buxus sempervirens	Leycesteria formosa
Philadelphus	Daphne Laureola	Box, of sorts
Hollies	Ruscus racemosus	Juniperus communis
Cornus alba	R. aculeata	J. sabina
C. sanguinea	R. Hypoglossum	Potentilla fruticosa
Corylus avellana	Ivies	Buddleia globosa
Daphne Mezereum	Privet, in var.	Vitis cordata Lantana
Buxus japonicus	Japanese Privet	V. Opulifolia
Lonicera tatarica	Common Laurels	Gaultheria Shallon
Xylosteum	Portugal Laurels	Ribes, of sorts
Mespilus germanica	Rhododendron ponticum	Weigela rosea
Rosa arvensis	Azalea pontica	Euonymus europaeus
R. rubiginosa	Taxus baccata	Berberis aquifolium
Rubus odoratus	Cotoneaster puxifolia	B. thunbergii
Sambucus nigra	C. microphylla	B. Darwinii
S. racemosa	C. Hookerii	B. vulgaris
Spirea sorbifolia	Perennita mucronata, for	Hippophae rhamnoides
S. thalictroides	peat soils	H. augustifolia
Symphoricarpos race-	Phillyrea, of sorts	Arbutus Unedo
mosus	Rhamnus Alaternus	Garrya elliptica
Acacia japonica	Broom	Sympatra racemosa

In planting shrubs with a view to produce shelter, ornamental effect, or game coverts, I would advise that they should never be scattered promiscuously over the ground as single specimens at wide distances apart, but should be planted in groups, say each plant three to four feet apart, and a mixture of a few kinds in a mass, taking care to keep the low-growing and less rambling sorts next to the wood rides. Of rough-growing herbaceous plants suited for covering the ground in summer, the following are good:—

Pentstemons, in vars.	Ribes Grass (3 varieties)	Asperula odorata
Spiraea officinalis	Carex pendula	Adonis purpurea
Spiraea Aruncus	Willow Herb	Lobelia syphilitica,
Vicia sylvatica, and its varieties	Perennial Sunflowers,	Strong coarse ferns, like—
V. major, and its varieties	double and single	Lastrea Filix mas
V. minor, and its varieties	Phytolacca decandra	and
Pampas Grass	Siberian Cow Parsnip	Common shade-loving
Sand Lyme Grass	Acanthus mollis	Ferns.
	Asclepias Coriaria	

G. B.

THE INDOOR GARDEN.

LILUM AURATUM.

THIS being the season for starting this charming Lily into growth, perhaps a few hints on its culture may not be uninteresting. It is a plant which no one fond of flowers should be without, whether they have a greenhouse or not.

The season before last I bought forty fine bulbs of this Lily, which gave me the utmost satisfaction. I planted them as soon as they arrived, in pots, in a mixture of peat loam, a little manure, and sharp sand. I put them first into small pots, and then, as these became full of roots, shifted them into larger ones, and so on, till they got into the large pots, in which they were to bloom for the season. Being rather pressed in the houses for room, I determined to try how some of them would do in the open border. Accordingly, I planted some of them out along with some lance-leaved Lilies, and they did splendidly; I, however, took the precaution to take them up as soon as they were well out of flower.

I had heard some people say that this Lily should be dried off; while others, on the contrary, said, "No; keep them in pots, and let them grow on;" so I tried half one way and half the other: I dried twenty, and kept the other twenty in pots.

Last season I started them into growth, but I only kept a dozen back for the conservatory, and, in place of plunging them in the pots, I turned them out. When they came into bloom, I found that those which I had kept growing on in the pots were twice as strong, and the flowers much larger than those I had dried off; I, therefore, made up my mind that for the future I should always leave them in the pots. Last season three or four were rather late in blooming, and, as I was afraid to leave them out of doors any longer on account of the frost, I thought I would try and lift them with a good ball, pot them, and see if they would bloom in the house later in the year. I was afraid that the lifting would give them a sad check; but it did not, and I had them in full flower on Christmas Day.

When my plants are growing I give them plenty of water; and when they are out of bloom, I do not dry them off suddenly, but keep giving less and less, till the stems are brown and decayed, when I stop watering altogether, and place the pots under a stage in one of the houses out of the way till I want to start them into growth next season.

Any one who will treat the bulbs of this Lily in the manner just described will find no difficulty in inducing them to bloom satisfactorily, even if they have no greenhouse; for they can be kept very well in the winter in a cold frame.

A. H.

Upper Norwood.

MONSTERA DELICIOSA.

For striking effect in warm conservatories arranged in the natural style this is a plant well worth attention on account of the size and singular appearance of its leaves, which, as our illustration shows, are cut and slashed full of holes in a peculiar manner, as well as divided into broad straps at the edges. Its habit is a good deal like that of a Philodenron. If grown for its fruit, it requires a brisk moist stove heat. The fruit is as peculiar in appearance as the leaves. It is about a foot long, and curved a little towards one side. Like that of the pine-apple, it consists of numerous "pips," which are arranged in a spiral manner round a central column, from which they separate readily when ripe. They are full of juice, the flavour and aroma of which is something like that of a pine-apple, luscious and pleasant to the taste, but soon satisfying; and being furnished with harsh papillæ they leave a disagreeable prickly sensation in the mouth, which is disliked by many. Nevertheless, some day or other this fruit may—nay, probably will—be introduced to our dessert as one of its choicest luxuries.

It is, however, with the uses of this plant in an ornamental point of view with which we have now to deal. Placed in conspicuous situations, where its great deep green, holed leaves could be seen to advantage, this singular Mexican Arad could not fail to excite curiosity and admiration. It should not be planted out, but kept in pots, which could be lifted from the

Monstera deliciosa.

positions in which they have been plunged and returned to the stove during winter. When grown luxuriantly it acquires a somewhat scrambling mode of growth, especially adapting it for creeping over or about massive rockwork, or rustic work, or over the back wall of a warm house. Trailing round a tropical pool where its ample foliage would be reflected by the water, its effect could not fail to be most satisfactory.

THEOPHRASTAS.

THEOPHRASTAS rank amongst the grandest of plants that are grown under glass for the beauty of their foliage. *T. imperialis* is unrivalled in its way, so much so indeed, as to make it a fit companion for medium-sized Palms, with which its ample, massive leaves contrast admirably. It also possesses the excellent property of being easy to cultivate, and by no means liable to the attacks of insects. Nor is it particular as to temperature. I have had it growing in the stove during the summer under a day temperature of 80°, and the same plant has been wintered in a house the night temperature of which has rarely been above 45°, without suffering in the least. It has one fault, and that is the difficulty—I might, indeed, say impossibility—of increasing it by any means except from seed. I have had cuttings, apparently in the best possible condition, taken off with a heel, that have lived for a couple of years, but have never made a single root.

Those commencing its culture should procure a plant at once, selecting such as has not been too long confined in a

small pot, for when that is the case this *Theophrasta* never makes a handsome plant; as it loses its bottom leaves sooner than it otherwise would do. Supposing the plant to be in a six or eight inch pot, full of healthy roots, remove it at once into a twelve or fourteen inch pot, well drained; using good turfy loam, with about one-seventh sand to insure good drainage, as it is a water-loving subject. It will succeed in a cool greenhouse, but its foliage is never so fine as when grown in the stove, with a night temperature of 70°, with a rise of 10° by day during the growing season. By next summer it will have filled the pot with roots, when it may be moved into an eighteen or twenty inch pot, using similar soil to that recommended at the first potting. During the growing season, syringe once a day and shade from bright sun. In the autumn it may be removed to a lower temperature, and it is not necessary to give it a larger pot, as the second season's growth can be assisted with manure water once or twice a week. By the end of the second summer, if all has gone well, the plant ought to be six feet high by six feet through. It will retain its bottom leaves about three years, when a few will begin to decay. As this goes on, if a portion of bare

Theophrasta.

stem is objectionable, the plant may be headed down, cutting the head off about three feet from the top; then, with a sharp knife cut out all the eyes down to within four inches of the base, which will induce it to break at the bottom, throwing out several shoots; remove these, all but one. When this has grown ten inches or a foot, the upper portion of the stump may be cut off just above where the young shoot has sprung. The reason for not heading the plant down to the base in the first instance is this: in all vegetable life there exists a perfect sympathy between the roots, the trunk, the branches, and the leaves; one cannot be mutilated or injured in the least degree without affecting the others; consequently, when the head of a plant is reduced, or altogether cut away, the roots die proportionately with the amount of head removed. Therefore, by retaining a considerable portion of the stem, we preserve a greater portion of roots, which, in their turn, are better able to assist nature in re-establishing the balance destroyed by removing the head of the plant.

When the young growth is a little further advanced, the plant may be taken out of the pot, the greater portion of the old soil removed, all the dead portion of roots cut away, and then placed in a smaller-sized pot, and subsequently treated as has just been directed. Brown scale is the only insect I have found troublesome, and this can be removed by sponging.

Southgate.

T. BAINES.

PALMS FOR THE GARDEN.

(Continued from page 369.)

HYPHENE THERAPICA (DOUW PALM: EGYPT).—Fronds, palmate, glaucous, with small spines on margin, also on petiole. A coarse-growing plant, quite unfit for pot cultivation.

H. NATALENSIS.—Similar to the last, but smaller.

IRIARTEA GIGANTEA (PERU).—Fronds, six to eight feet long, bipinnate; pinnae, triangular, six inches long, four inches broad, spreading. A noble Palm, resembling a gigantic *Adiantum*; roots strong, often cropping up above the ground, three-quarters of an inch thick. Well adapted for a large house, where it contrasts well with other plants; fond of heat.

JUBEA SPECTABILIS (SYN., *COCOS CHILENSIS*: NEW GRENADA).—Fronds, pinnate, spreading, channelled on upper side, eight to ten feet long, shining green. This plant has the habit of a Phoenix, and being nearly hardy is useful either for cool conservatory or outdoor decoration. It is reported to stand our winters; but it does best when slightly protected.

KENTIA CANTERBURYANA (NORTH QUEENSLAND).—Fronds, spreading, pinnate; pinnae, flat, regular, acuminate; leaf-stalk, round; habit, that of the Areca, but stiffer. We have three species of this genus from the same district, differing in habit and width of pinnae. All of them are of noble port, and should withstand greenhouse treatment. As they grow old, the fronds form a beautiful plume-like circle of foliage, borne upon a stem about one and a half inches in thickness.

K. MOOREANA.—Smaller than the last; fronds recurved.

K. WENDLANDII.—The dwarfest of the three; habit, denser; pinnæ, broad.

KORTHALIA DEHLIS (BORNEO).—Fronds, erect, pinnate; pinnae, flat, two to three inches broad, dark green. When young this has the habit of *Areca catechu*, but is slighter. A good vase plant for table decoration.

LATANIA CAMERONII (SYN., *RUBRA*: MAURITIUS).—Fronds, palmate, three to four feet broad, points acute, cut about six inches, margin red; petiole, glaucous, with small spines on margin; underside round, upper, flat. A good table plant when young, at which period it is of a red tint; with age the colour goes off, when it becomes a truly noble object for a large house, throwing magnificent foliage. Where there is room this is the palm of palms.

L. GLAUCA (SYN., *LODDINGESEI*: MAURITIUS).—Habit, exactly that of the former; differing in the absence of the red margin and the whole plant being glaucous. A noble plant.

L. VERSCHAFELLI (SYN., *AUREA*: MAURITIUS).—Plant laxer than the above; petiole, unarmed, slightly recurved, with a yellow tint which pervades the whole plant; leaf, cut nearly half way. A good plant to mix with other foliage plants for contrast. When small, a very good table plant, though not fond of cold.

LEOPOLDINIA PULCHRA (BRAZIL).—Fronds, pinnate; pinnae, recurved, purplish in tint; unarmed. A good Palm, on account of its purple shade for mixing with fine-foliated plants, though not so good as its name would denote.

LICULALA ACUTIFIDA (MOLUCCA).—Fronds, forming a circle, cut into segments about half way; points, acute, drooping; stiff spines on margin of petiole. The whole of this genus are round-leaved plants, of more compact habit than Latanias, therefore more useful for small houses and table decoration. This is the best species; all are fond of heat and water.

L. ELEGANS (SUMATRA).—Leaf, cut into eight or ten segments; point, abrupt; a good plant; when young it has eight to ten fronds, and spreads from three to four feet.

L. HORRIDA (JAVA).—A stiff-looking plant, with dark-green foliage; strong, dark spines on margin of petiole. Not very desirable.

L. PELTATA (INDIA).—Leaf, very round and flat; end cut abruptly; petiole, spinose. This is a very elegant plant, gaining beauty with age.

L. SPINOSA (JAVA).—A stiff, short-leaved plant. Not decorative.

LIVISTONA ALTISSIMA (SYN., *SUBLONGLOSA*: JAVA).—Fronds, fan-shaped, nearly round; points, pendent; petiole, long, erect; spines on margin. A slighter plant than *L. chinensis*, but not so hardy. A very useful palm.

L. CHINENSIS (SYN., *BORBONICA*: ISLE OF BOURBON).—Fronds, spreading, dense; points, pendent; spines on petiole recurved. This plant is a general favourite, though not the best of the genus. A good plant for subtropical purposes and a large house; but for a small one it is too dense.

L. HOGGENDORFII (JAVA).—Petiole, set with strong black spines; fronds, larger and more erect than *L. chinensis*. Fond of heat.

L. HUMILIS (N. HOLLAND).—Erect and spreading spines on petiole, half way from base; leaf forming three-quarters of a circle, dark green. Good for conservatory, though rather dense.

L. INERMIS (N. HOLLAND).—This resembles, in general appearance the above; but the leaves form a circle, and are denser.

L. JENKINSII (ASSAM).—Fronds, forming three-quarters of a circle; ends, pendent; spines on petiole, distant. A light-looking plant, which when young is very elegant, spreading from three to four feet. One of the best for stove purposes.

L. OLIVÆFORMIS (JAVA).—Very like *L. chinensis*, but not so hardy. *L. ROTUNDIFOLIA* (SYN., *SARIBUS*; JAVA).—A compact plant, with short, round leaves, bright green; spines on petiole, black. When young, it forms a good-shaped plant, at the height of two feet, and one foot wide; in fact it is the gem of the genus. Though rather dense for table purposes, it is good for mixing with ferns in a small house.

L. MAURITIANA.—There is a plant in cultivation under this name, but I have not been able to distinguish it from *L. chinensis*, either by seed or plant.

J. CROUCHER.

(To be continued).

DARLINGTONIA CALIFORNICA.

This, in some respects, extraordinary plant has probably not yet become common in England. When first introduced, I remember it was considered a difficult plant to manage; it frequently refuses to grow, and, in some cases, dies outright, probably from over kind treatment. Some account, therefore, of the way in which we manage it in America may not be without interest, showing, as it does, that we experience no difficulty in the least in making it grow satisfactorily. The first lot of plants which I received was during the hottest part of the summer, and although taken up when in full growth, sent five hundred miles to San Francisco, and afterwards 3,300 miles by rail to this place, they came to hand in capital condition. I potted them at once in rough peat and live sphagnum, and placed them outside in a small stream of water, shading well for a few days, and then left them exposed until quite a sharp frost occurred at the end of October, when they were removed to a cold house, or rather, to the cold end of a very cool house, with such associates as *Sarracenia purpurea*, the variegated New Zealand Flax (*Phormium tenax variegatum*), young *Thujopsis*, &c. Here they were plunged in sphagnum, kept wet, and sprinkled overhead every day. Thus treated, they succeeded to my entire satisfaction; but I expect even better results from plants taken up in the autumn; for a large batch which I received last autumn made a greater number of fresh roots in less time than did those received in summer.

I would strongly recommend plantations of this plant and of *Sarracenia purpurea* to be made round ornamental waters. The *Sarracenia* will withstand a temperature 10° below zero, and probably one even more severe; but I can vouch for its enduring that amount of frost, and I have no doubt that the *Darlingtonia* will, at least, withstand the vicissitudes of an English winter. It would only be necessary to make for it a bed of rough peat, and to allow the roots to reach the water.

South Amboy, New Jersey, U.S. JAMES TAPLIN.

ROSES ON ORANGE TREES.

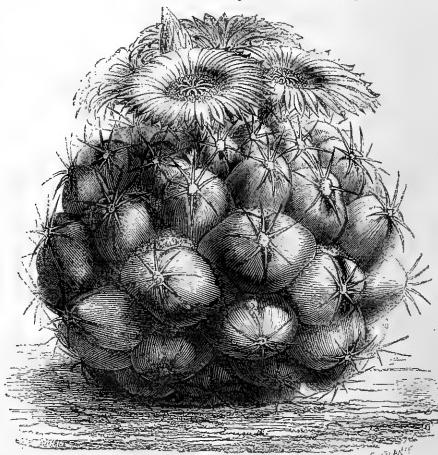

In the month of March I procure orange trees about one to two feet high, and two to three inches in diameter, take them out of their boxes or pots and shake the soil entirely off their roots; then I wrap the stem in a thick woollen cloth and screw it into a vice, cut off its tap-root, get an augur a little longer than the stem of the tree, and begin to bore from the place where the tap-root was cut off through the pith of the stem, exactly through the very centre of the tree, until the point of the augur appears through the crown. The cavity, after I have withdrawn the instrument, I clean out with a small brush fixed to a stick, so that no loose wood remains. I then melt a little beeswax and turpentine together, and with this mixture I paint the interior of the tree. After this I get a dog-briar with good roots, and nearly as thick as the cavity in the orange tree, but about two or three inches longer than the tree itself, remove all thorns from it, and pass it through the tree from the root upwards, so that the roots of the tree and the briar mingle together. Around the top and the bottom of the rose tree I place a little grafting-wax to prevent the air and soil getting into the cavity. Then I pot the tree again, and prune it closely, and place it into bottom heat. In four or five weeks I bud the top of the briar, and very often the same year I have had orange blossoms and rose-flowers together. The orange tree does not take the operation amiss, but goes on flowering and fruiting as if nothing had happened. Last year I saw some of these orange

trees I had grafted to rose trees fifteen years ago on the Continent full of flowers—roses and orange blossoms, mingled together. In a year afterwards it is impossible to detect how the operation was performed, and the tree looks exactly as if a rose had been grafted upon it.

G. S., Cheltenham.

MAMMILLARIA ELEPHANTIDENS.

This is one of the most distinct of the elegant section of Cacti to which it belongs. In July, August, and September, it produces a quantity of purple and violet-shaded flowers, two inches in diameter. It is beset with strong spines, which are reflexed; they are, therefore, not so formidable-looking as those of some of the species. The plant itself is bright green in colour, and very free growing. It may be used as a rock-plant in summer in an exposed situation. It will even stand a temperature as low as 35° in winter, and may be kept out of the soil in a perfectly dry state until next season. It increases very fast by means of offsets from the points of the mammæ. Many others among dwarf Cacti

Mammillaria Elephantidens.

would show to advantage if they were used for bedding purposes, or on rockwork, as, for instance, *Echinopsis Eryresii*, which may be increased to any extent, and would be an improvement on *E. sempervirens*.

J. CROUCHER.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Palms for Table Decoration.—Kindly name a few for this purpose.—A. D.—[The following are very ornamental in a young state, viz.:—]

<i>Arecia lutescens</i>	<i>Latania borbonica</i>	<i>Calamus ciliaris</i>
<i>Chamaedorea Hartwegii</i>	<i>Livistona rotundifolia</i>	<i>C. viminalis</i>
<i>C. Sapotina</i>	<i>Ricinus palmiformis</i>	<i>C. leprosus</i>
<i>C. elegans</i>	<i>Sebastodes Baccari</i>	<i>C. leptophyllum</i>
<i>Demonocarpus fissus</i>	<i>Thrinax, in var.</i>	<i>Caryota urens</i>
<i>D. periantha</i>	<i>Wallichia caryotoides</i>	<i>Euterpe sylvestris</i>
<i>Elaeis guineensis</i>	<i>Veitchia Johannis</i>	<i>E. edulis</i>
<i>Geonoma pumila</i>	<i>V. australis</i>	<i>Hypophorbe Verschaffeltii</i>
<i>G. Verschaffeltii</i>	<i>Kenia canterburyana</i>	<i>Licuala elegans.</i>
	<i>Cocos Weddelliana</i>	

Plantains and Bananas?—What is the difference between Plantains and Bananas? Kindly say, and oblige.—MUSA.—[The fruit of the plantain is about an inch in diameter, from five inches to eight inches in length, and bent a little on one side. The fruit of the banana is much shorter and rounder in form, and more agreeable in flavour, though not so juicy as that of the plantain. The trees of both species grow from fifteen to twenty feet high, and are readily distinguished from each other, as the stem of the plantain is entirely green, while that of the banana is spotted with purple. The one generally grown and often fruited in our stoves is the Duke of Devonshire's *Musa*, *M. Cavendishii*, or *chinessis*; it may be called the dwarf banana, as it is more stocky in habit than either the true plantain or banana. It is indeed so compact in habit that it may be easily fruited in a common stove or cucumber house.]

Dracænas and Caladiums.—Which are the best Dracænas and Caladiums for a cool greenhouse or a room window?—J. V. R.—[Caladiums dislike draughts or a too dry or cool atmosphere. Dracæna will do. Try the following:—Dracæna australis, Draco, indivisa, brasiliensis, nutans, Rumphii, erythrorachis, cannaefolia, lineata, excelsa, robusta, ferrea, nigricans.]

Hybridising Pelargoniums.—Will any of your readers acquainted with hybridising Pelargoniums be so obliging as to state how the operation is effected, and at what stage the flowers must be when operated on?

INQUIRER.—[A master of new varieties, who has had twenty years' experience, informs us that the process of cross-breeding must be learnt by practice; it cannot be taught in books. But he gives these hints as aids to beginners: Pollen is usually to be had from any variety, so do not be anxious about that. Your first care should be to fix on the seed-bearing flower, and the moment it begins to open, and before it is open, take a tiny pair of scissors, and cut out the stamens. This is to prevent its being fertilised by its own pollen. Now you may think of the pollen to fertilise it with; and on the second day after the flower opens the stigma is usually fully developed, and the cross will take. The smallest particle, applied by a camel's hair pencil, is enough, and it should be applied at mid-day.

TOWN GARDENING.

"OUR SQUARE" AND ITS HISTORY.

The open spaces in London devoted to a little greenery of trees, grass, and flowers, are such invaluable cases in our great desert of bricks and mortar, that an interest in the methods of their planting and "keeping up," so as to insure the greatest amount of enjoyment, becomes the duty of every citizen who can now and then spare a stray half hour from the absorbing duties of ordinary life routine. If such men, and women too, who are residents in London, and yet have had opportunities of cultivating a taste for gardening, would devote a few of the above-named half hours in endeavouring to influence stolid vestrymen and others to a sense of duty in such matters, we should soon see a vast improvement in those green features of the great city, which ought to be so attractive, but which are often so much the reverse, as in the unfortunate example of Leicester Square. "Our Square" is but a comparatively small open space; but yet, properly treated, might be made very pleasant to the eye from our drawing-room and dining-room windows, enabling us to look gratefully upon a small expanse of green, chequered in summer with the many vivid hues of gay flowers, instead of compelling our outward gaze to travel right across the open space and meet the dingy façade of houses on the opposite side, which, though not quite so close upon us as those of an ordinary street, are yet somewhat too near; while their architecture, though tolerable enough for the stucco school of domestic Corinthian, does not call for a continual study of its decorative features.

The pleasing temptation to the eye to rest half away across, among the green turf and gay flowers has not, however, been realised by the speculative builder who assumed to himself the position of *arbiter elegantiarum* in the matter of this town garden, the result of his inscrutable design being that which is about to be described. First: he wisely enough considered that, as the space was not large enough to serve as a promenade to the inhabitants of the square, it would, if left open, be made a mere playground for nursesmaids and children, to the rapid destruction of any floricultural attempts he might feel disposed to make, in his natural wish to impart an agreeable aspect to his property. With this view, it was determined that the inhabitants should not be admitted within its railings, and that there should be no walks, in order not to encourage any latent wish to lounge forth in the cool of a summer evening among the flowers and shrubs of the square. The whole of the enclosure was, consequently, laid down in turf, in which were planned certain geometrical flower-beds, to be filled in summer with Geraniums and other "bedding plants." So far, the plan was consistent enough; but what was the subsequent "move"? Why, incredible as it may seem, the tasteful builder-proprietor, in order to guide his next step, looked to the example of other squares and their arrangements, not wishing, as it would seem, to run too much in the face of established custom all at once; and finding that they were almost invariably planted

inside the palisades with close hedges of Privet or Holly where either would grow, he at once went and did likewise. The effect of this last stroke of genius being, that our grass and flowers, which we were only allowed to inspect from the outside, were thus entirely concealed from us by a thick hedge of Privet and Holly; which soon became a ragged soot reservoir, that effectually hid the flowers from us, as by the interposition of a murky, smoke-blackened veil.

It should be remarked that the concealment only took effect when the spectator sought a glimpse of the flowers from the level of the street; and that it merely prevented him from standing and staring at the Geraniums on his road home to dinner, which perhaps might be getting cold while he was indulging in flower-admiring ecstacies; and so, it might be argued, the enchantment was wisely shut out from his view.

It may be urged, on the other hand, that lovers of flowers and of the soft and soothing aspect of a bit of green turf, might deem a glimpse of them agreeable from the dining-room windows, and might consider that their being shut out from that point of view was, in a small way, a kind of hardship. But to this aspect of the case the advocate of the tasteful builder might again reply by telling us that when in the dining-room, instead of straining the sight after the distant flowers in the enclosure, it would be far wiser to concentrate the powers of the visual organs on the cauli-flowers close at hand on the table. This, for a moment, might appear tolerably conclusive: and, it might be further remarked, that from the drawing-room windows (a much more suitable position for the indulgence of reveries about flowers), we could obtain a nice comfortable view over the top of the black and sooty veil of Privet and Holly. But that ingenious form of advocacy was carefully provided against by the ingenious plotter and planner of our little oasis; for, in addition to the hedge of Holly and Privet, he also surrounded the enclosure with the tallest young Limes and Planes that he could get; and they have thriven sufficiently well to form a tolerably dense screen, which obscures the view of the grass and flowers as effectually from the level of the drawing-room windows as the black hedge did from the pavement and the windows of the dining-room. It is true that from the upper rooms of the house a sort of bird's-eye glimpse could be obtained; and the housemaids told their mistresses that from the attic windows the summer view of the Geraniums in the square was beautiful. It might be so, and it was no doubt a source of gratification to know that the maids had a nice view from the top of the house, but it did not quite satisfy the denizens of the drawing-room.

Such was the state of things up to Christmas last, when our garden Maecenas was induced, after many struggles against deep-rooted convictions, to take away the dingy hedge, bring the turf close up to the palisades, and allow us to get a peep at the flowers and grass. But he persistently retained the Limes and Planes; and it will evidently require another little revolution, "all or the square," before his opposition to our views is thoroughly uprooted. In the meantime we have just induced him, *en attendant* the season of Geraniums, &c., to fill the great round central bed with Wallflower plants, which already form a pleasing mass of fine deep-green in place of a bare patch of black earth, and in a short time masses of bright golden flowers will mingle with the sober foliage, and fill the atmosphere of our little square with grateful fragrance. These are steps in the way we want to go, and we must patiently await others. Garden reforms, like the trees themselves, must grow; they cannot be effectually secured *per saltum*, for if done all at once, reaction is always to be dreaded. In our horticulture, as in our "glorious constitution," we must be content to train and develop, for that has proved the secret of permanence in our institutions of all kinds, from gardening to politics; and so, the trees of the square have full faith in the uprooting, in due time, of the objectionable Limes and Planes of our little enclosure, and the removal of one or two of them to a central mound, where with a third, fourth, and perhaps fifth additional tree of different kinds, the group may form itself into a pleasing mass of foliage, and prove an admirable nucleus from which the other garden features should radiate in graceful and not too regular lines; the whole composition becoming uninterruptedly visible to the inhabitants from the dining room to the attic. H. N. II.

THE PICTURESQUE SPRINGS OF FLORIDA.

The springs of Florida, as described by a newspaper correspondent, appear to be so copious and so picturesque, that, while there is yet time, they ought to be secured as national property, never to be vulgarised by cotton mills or other commercial undertakings, but made the central objects of national parks, as in the case of the magnificent Yosemite Valley in California. These springs in the State of Florida are so wonderful as almost to surpass credibility. One of these, called "The Big Spring of Chipola," is literally a river bursting out of the earth from under a high bank covered with large oak trees. The orifice is thirty feet by eight wide, and the stream forms a river six rods wide and eight feet deep, which joins the Chipola River, and makes its way to the Gulf. Another, named "Silver Spring," in the county of Marion, is perhaps more accessible to the tourists on the St. John's River, and is large enough to admit to its very source the steamers that navigate the Ocklawaha River. Within a hundred yards of my present residence, from a wide cleft in a rock some eighteen feet down, breaks forth a living stream, which, with lavish generosity, pours out its tide at the rate of three thousand gallons per minute. Another hundred yards, and the stream is lost in the dark solemn waters of the St. John's River; but if it rose on high ground, and in the interior, it would be sufficient I fancy to turn all the mills of Lawrence or Lowell. And yet Green Cove Spring does not take high rank in Florida for its magnitude, though in beauty I should say that it yields to none. The waters are beautifully clear, and the bottom, which is some twenty feet square, is covered with a rich emerald. All around the spring, and almost overhanging it, are the graceful forms of semi-tropical vegetation, both trees and shrubs, in richest profusion—the magnolia, water oak, dwarf palm, &c.; the trees all decorated with the soft, yet exquisite drapery of the trailing moss. Birds, quite secure, sit about and lend their forms and song to fill up the picture. The trees and shrubs are mostly evergreen. In a week more (February 20) all those not now in leaf will be putting forth their foliage, and flowers will be springing up in every direction. In short, one here enjoys summer in the month of February.

Grass.—Gather a single blade of grass, and examine for a minute quietly, its narrow sword-shaped strip of bluted green. Nothing, as it seems there, of notable goodness or beauty. A very little strength, and a very little tallness, and a few delicate long lines meeting in a point—not a perfect point neither, but blunt and unfinished, by no means a creditable or apparently much-cared-for example of Nature's workmanship; made, as it seems, only to be trodden on to-day, and to-morrow to be cast into the oven; and a little pale and hollow stalk, feeble and flaccid, leading down to the dull brown fibres of roots. And yet, think of it well, and judge whether of all the gorgeous flowers that beam in summer air, and of all strong and goodly trees, pleasant to the eyes or good for food—stately palm and pine, strong ash or oak, scented citron, burdened vine—there be any by man so deeply loved, by God so highly graced, as that narrow point of feeble green. It seems to me not to have been without a peculiar significance that our Lord, when about to work the miracle of all that He showed, appears to have been felt by the multitude as the most impressive—the miracle of the loaves—commanded the people to sit down by companies "upon the green grass." He was about to feed them with the principal produce of earth and the sea, the simplest representations of the food of mankind. He gave them the seed of the herb; He bade them sit down upon the herb itself, which was as great a gift, in its fitness for their joy and rest, as its perfect fruit for their sustenance; thus, in this single order and act, when rightly understood, indicating for evermore how the Creator had entrusted the comfort, consolation, and sustenance of man, to the simplest and most despised of all the leafy families of the earth. And well does it fulfil its mission. Consider what we owe merely to the meadow grass, to the covering of the dark ground by that glorious enamel, by the companies of those soft, and countless, and peaceful spears. The fields! Follow but forth for a little time the thoughts of all that we ought to recognise in those words. All spring and summer is in them—the walks by silent, scented paths—the rests in noonday heat—the joy of herds and flocks—the power of all shepherd life and meditation—the life of sunlight upon the world, falling in emerald streaks, and failing in soft blue shadows, where else it would have struck upon the dark mould, or scorching dust—pastures beside the pacing brooks—soft banks and knolls of lowly hills—thymy slopes of down overlooked by the blue line of lifted sea—crisp lawns all dim with early dew, or smooth in evening warmth of barred sunshine, dintered by happy feet, and softening in their fall the sound of loving voices: all these are summed in those simple words; and these are not all.—*John Ruskin.*

THE LIBRARY.

FLOWERS AND GARDENS.*

A PLEASANT and singular little book, discoursing agreeably about some of our old garden favourites. The subject is approached from the aesthetic side, and the author appears to us to take a true and just view of most of the subjects upon which he touches. The following extract will serve to give an idea of the style and aim of the book, to which we shall probably again advert:—

"I believe that nearly every plant has an especial loveliness of its own—a something distinctive, that is, which is capable of endearing it to us. And though such degraded forms as *Torilis nodosa* may attract us chiefly as curiosities in all but exceptional instances, this loveliness finds itself upon some form of genuine beauty—beauty, I grant, which, as a whole, is often of an inferior order; thus there is nothing to strike the eye in the common wild *Mignonette*, or in many of the *Galiums*, *Willow-herbs*, *Groundsels*, *Rushes*, *Sedges*; and yet it frequently happens that these plants, not generally attractive, excel at particular times and in particular ways. Usually few people would admire the *Yellow Charlock*, yet what splendour it often casts over the yet green corn-fields when blended with the scarlet of the *Poppies*! *Anthriscus vulgaris*, *sylvestris*, and many of the *Umbelliferae* are remarkable for the beauty of their earliest leaves; those especially of the great *Cow Parsnip* might serve as models for the stone carver; and the coarse insignificant *Goosegrass* (*Gallium aparine*), which children rub over their tongues to make them bleed, fills every hedge bottom in January and February with a host of tiny star-crosses as delicate as the work of fairies. Then observe that tall *Anthriscus sylvestris* later on in June, how it varies the long level of many an unknown meadow with the dull misty white of its flowers, giving, by the looseness of its growth, a wild, indefinite look, here and there almost reminding us of tumbled foam, an effect which is greatly aided by the meanness and unimpressiveness of its foliage. Then the two common *Dead Nettles* (*Lamium*) are very undeservedly depreciated. The red *Dead Nettle* is one of our earliest spring flowers, and there is a soft vividness in the red, especially in the earlier blossoms, which leads off most exquisitely through the purplish tints of the upper leaves. As to the white *Dead Nettle*, I will say nothing of it in the spring-time, when it is outshone by more brilliant rivals. I always prefer it when the November mists are falling, and its large soft flowers, undamaged by the weather, look forth here and there from the hedge. Truly, they have a wonderful fascination then. In early spring the plant has a too excessive vigour—an air of rude health, which often spoils it, partly, I think, by affecting the leaf colour; besides, the stems are apt then to be far too numerous. It is otherwise in November."

"Plants are thus far more universally beautiful than animals, because plants can never disgust or repel—animals can. And though it were easy to name plants in which one feels no vivid interest, as, for instance, *Seneio sylvatica*, I find, on running through our native lists, these to be comparatively so few, that the fault lies most probably with the observer."

THE CULTURE OF THE PEAR.†

THIS is one of those thoroughly practical, and therefore scientific, little books on fruit culture which one so often meets with in France. In it the culture of the pear is concisely and lucidly given, together with full descriptions of select kinds and their special wants, if any. M. Baltet is in all respects an excellent writer. There are some who ridicule gardening literature, and if they confined their ridicule to that which is bad they might be right; but a good book is the harvest of a good man's thoughts so arranged as to be easily digested, and, therefore, like that before us, commands itself to our favourable notice. We have no doubt that such publications as this have had much to do with the excellent pear culture one sees in every part of France.

Garden Flowers. (London and Edinburgh: Nelson & Sons.)—A packet of twelve small coloured plates, each representing a group of garden flowers, the whole in a neat packet. The flowers are charmingly grouped, and for the most part well coloured. We particularly admired a group of Foxglove and Harebells. We heartily welcome this effort to popularise such pretty objects. The packet forms a suitable little present, and the plates will give pleasure in many a home where living flowers are never seen; while in the home blessed with a garden, where flowers are "all a blowin' and a growin'," they will testify how well the artist has expressed their beauty in these cheap little pictures.

FAMOUS TREES.

THE DRAGON TREE.

(DRACENA DRACO.)

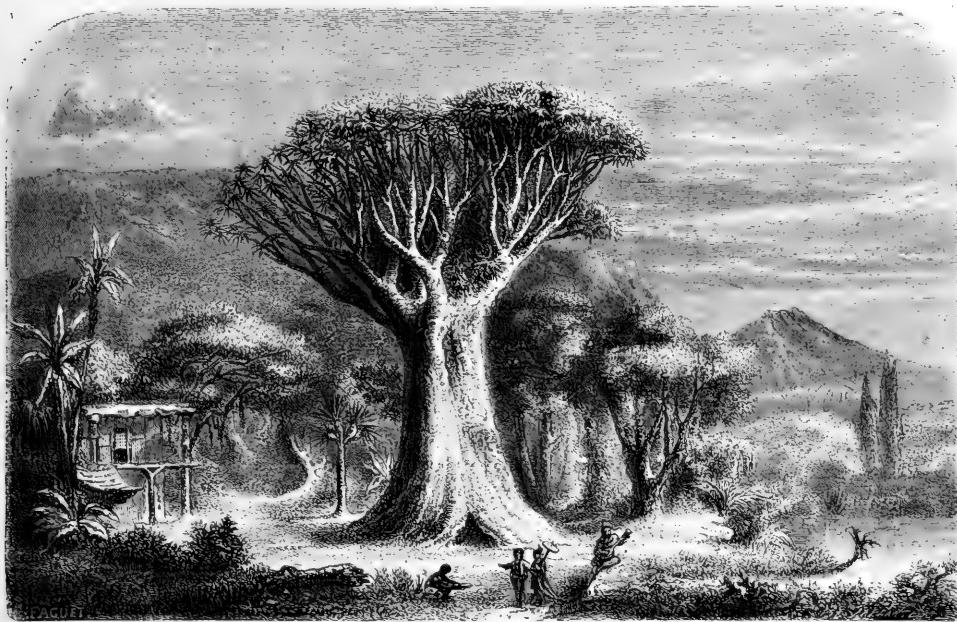

The giant specimen of Dragon Tree, growing at Orotava, in the island of Teneriffe, was entirely destroyed during the autumn of 1867 by a gale of wind. It was first brought into general notice by Humboldt, some sixty years ago, and was computed by him to be 6,000 years old. It had, however, been previously noticed in 1797 by Sir George Staunton, and in 1771 by T. C. Borda, a Frenchman, whose drawing of the tree was subsequently published by Humboldt. In July 1819 a storm deprived it of part of its crown, and a large and good English engraving of it was published after its mutilation. Webb, in his "Natural History of the Canaries," describes it and gives its measurements, and it has since afforded a theme for the pen of almost every traveller who has visited Orotava.

not to be wondered at, for even in their native country they attain the age of thirty years before they emit branches.

This tree is usually known by the name of Dragon's-blood Tree, on account of a resinous exudation which it emits at certain times from cracks in the trunk. At one time the resin formed a considerable branch of commerce, being highly esteemed in medicine, but it has now almost fallen into disuse.

As a type of tropical vegetation it is peculiar, and worth attention on account of the contrast it makes with other forms of plant-life with which it is associated. Young plants of this species are valuable for the conservatory at all seasons, and for placing out of doors in summer in the warmer parts of these islands.

The Looshai Highland Flora.—Now that the Looshai mountaineers have been punished for their raids on our Assam tea plantations, and the prisoners they had carried off recovered, science will probably derive unexpected advantages from the opening-up of

The Dragon Tree (Dracena Draco).

The trunk was hollow, and in the interior was a staircase, by which one might ascend as far as the part from which the branches sprung. It was said to be seventy feet in height, and, according to Le Duc, seventy-nine feet in circumference near the ground; it was supposed to be one of the oldest vegetable inhabitants of the world. We have plants of *Dracema Draco* in our stoves; but so unlike are they to the wonderful specimen represented by our illustration, that nobody would imagine for a moment that they were one and the same thing—so wide is the contrast between youth and age.

Dracema Draco is a native of the East Indies, but the Canary Islands seem to have suited its growth admirably. It has a tree-like stem, much branched at the top, where they form a crowded head of lanceolate linear entire leaves, of a glaucous green colour. The leaves embrace the stem at their base, and on falling off at maturity leave a scar on the branch. In our stoves the plants are usually unbranched, a circumstance

the Looshai highlands. The fauna and flora of those extensive mountain ranges are almost entirely unknown to science. Of the former it is true we know something through the skill of the native tribes in trapping several kinds of birds of beautiful plumage which are found in the forests, and which they bring for sale to our frontier stations; but of the plants of that region we know next to nothing. Communications are now, however, opened-up, which will doubtless lead to successful explorations; and beautiful plants, hitherto unknown, may possibly reward our researches. It was, comparatively speaking, but the other day that the magnificent Himalayan Rhododendrons were discovered by one of our most justly celebrated botanists, and though letters received during the Looshai expedition may, perhaps, have raised our expectations too high, yet it is but fair to suppose that some valuable additions will be made to our exotic flora, which will add many new and attractive features to our gardens—the more especially as coming from a mountainous region many of them may prove fully as hardy as some of the new Rhododendrons and other plants received from the Himalayas.

GARDEN DESIGN.

WATER.

In considering the subjects of gardening, ground and wood first present themselves; water is the next, which, though not absolutely necessary to a beautiful composition, yet occurs so often, and is so capital a feature, that it is always regretted when wanting; and no large place can be supposed, a little spot can hardly be imagined, in which it may not be agreeable; it accommodates itself to every situation; is the most interesting object in a landscape, and the happiest circumstance in a retired recess; captivates the eye at a distance, invites approach, and is delightful when near; it refreshes an open exposure; it animates a shade, cheers the dreariness of a waste, and enriches the most clouded view: in form, in style, and in extent, may be made equal to the greatest compositions, or adapted to the least; it may spread in a calm expanse, to soothe the tranquillity of a peaceful scene; or, hurrying along a devious course, add splendour to a gay, and movement to a romantic situation A gently murmuring rill, clear and shallow, just gurgling, just dimpling, imposes silence, suits with solitude, and leads to meditation: a brisker current, which wantons in little eddies over a bright sandy bottom, or bubbles among pebbles, spreads cheerfulness all around; a greater rapidity, and more agitation, to a certain degree are animating; but in excess, instead of awakening, they alarm the senses; the roar and the rage of a torrent, its force, its violence, its impetuosity, tend to inspire terror; that terror, which, whether as cause or effect, is so nearly allied to sublimity. Abstracted, however, from all these ideas, from every sensation, either of depression, composure, or exertion; and considering water merely as an object, no other is so apt soon to catch, and long to fix the attention In a garden, water is generally imitative. That which in the open country would be called a great pond, there assumes the name, and should be shaped as if it had the extent of a lake; for it is large in proportion to the other parts of the place." Though sometimes a real river passes through a garden, yet still—but a small portion of it is seen; and more frequently the semblance only of such a portion is substituted instead of the reality. In either case, the imitation is lost, if the characteristic distinctions between a lake and a river be not scrupulously preserved.

THE LAKE.

Space is essential to a lake; it may spread to any extent; and the mind, always pleased to expand itself on great ideas, delights even in its vastness. A lake cannot be too large as a subject of description or of contemplation: but the eye receives little satisfaction when it has not a form on which to rest: the ocean itself hardly atones by all its grandeur for its infinity; and a prospect of it is, therefore, always most agreeable, when in some part, at no great distance, a reach of shore, a promontory, or an island, reduces the immensity into shape. If the most extensive view which can be the object of vision, must be restrained, in order to be pleasing; if the noblest ideas which the creation can suggest, must be checked in their career, before they can be accommodated to the principles of beauty; an offence against those principles, a transgression of that restraint, will not easily be forgiven on a subject less than indefinite: a lake whose bounds are quite out of sight, is circumscribed in reality, not in appearance; at the same time that it disappoints the eye, it confines the imagination; it is but a waste of waters, neither interesting nor agreeable. If the length of a piece of water be too great for its breadth, so as to destroy all idea of circuituity, the extremities should be considered as too far off, and made important, to give them proximity: while at the same time the breadth may be favoured, by keeping down the banks on the side. On the same principle, if the lake be too small, a low shore will, in appearance, increase the extent. But it is not necessary that the whole scene be bounded: if form be impressed on a considerable part, the eye can, without disgust, permit a large reach to stretch beyond its ken; it can even be pleased to observe a tremulous motion in the horizon, which shows that the water has not there yet attained its termination. Still short of this, the extent may be kept in uncertainty; a hill or a wood may conceal one of the extremities, and the country beyond it, in such a manner, as to

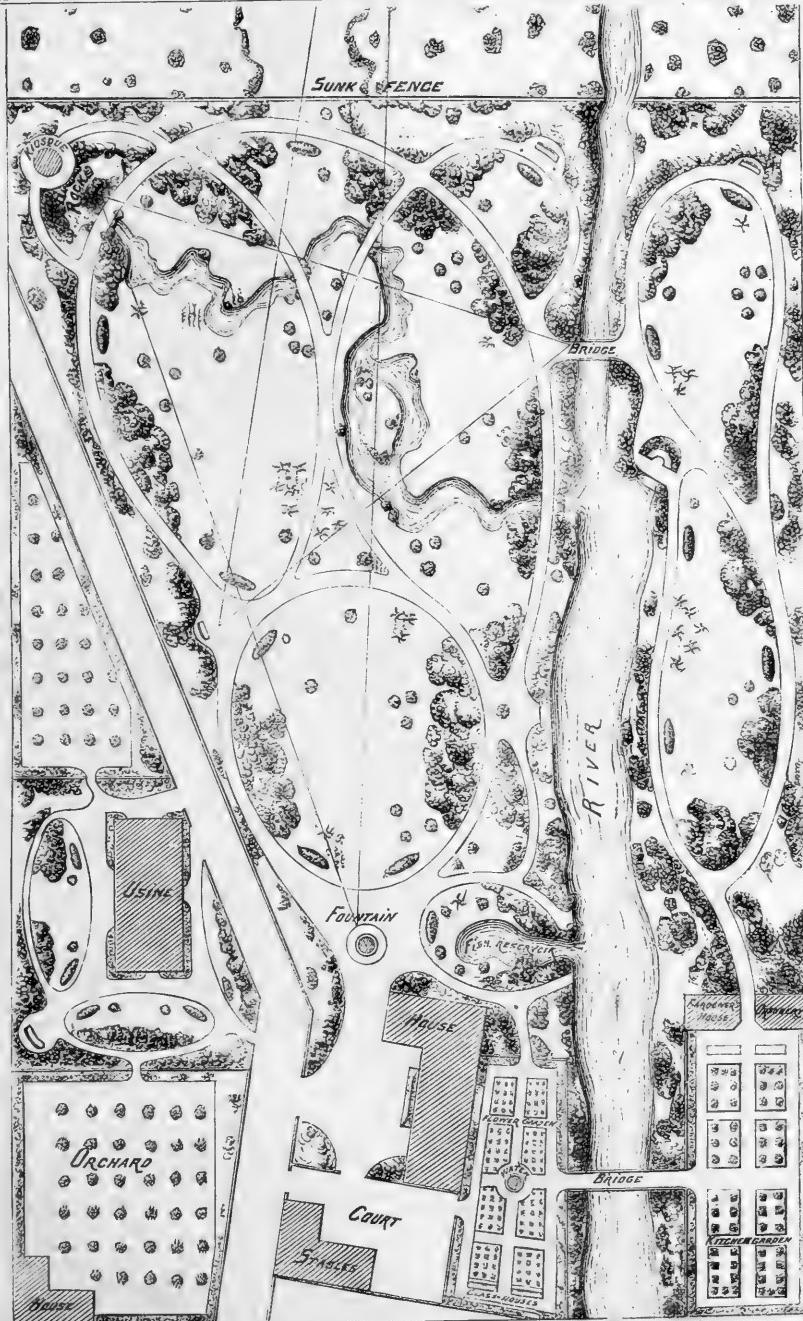

leave room for the supposed continuation of so large a body of water. Opportunities to choose this shape are frequent, and it is the most perfect of any: the scene is closed, but the extent of the lake is undetermined; a complete form is exhibited to the eye, while a boundless range is left open to the imagination. But mere form will only give content, not delight; that depends upon the outline, which is capable of exquisite beauty; and the bays and the creeks, and the promontories, which are ordinary parts of that outline, together with the accidents of islands, of inlets, and of outlets to rivers, are in their shapes and their combinations an inexhaustible fund of variety. A straight line of considerable length may find a place in that variety; and it is sometimes of singular use to prevent the semblance of a river in a channel formed between islands and the shore. But no figure perfectly regular ought ever to be admitted; it always seems artificial, unless its size absolutely forbids the supposition. A semi-circular bay, though the shape be beautiful, is not natural; and any rectilinear figure is absolutely ugly; but if one line be curved, another may sometimes be almost straight; the contrast is agreeable; and to multiply the occasions of showing contrasts, may often be a reason for giving several directions to a creek, and more than two sides to a promontory. Bays, creeks, and promontories, though extremely beautiful, should not, however, be very numerous; for a shore broken into little points and hollows has no certainty of outline; it is only ragged, not diversified; and the distinctness and simplicity of the great parts are hurt by the multiplicity of subdivisions: but islands, though the channels between them be narrow, do not so often derogate from greatness; they intimate a space beyond them whose boundaries do not appear; and remove to a distance the shore which is seen in perspective between them. Such partial interruptions of the sight suggest ideas of extent to the imagination.—*Thomas Whateley.*

ARCHITECTURE AND NATURE.

We are forced, for the sake of accumulating our power and knowledge, to live in cities: but such advantage as we have in association with each other is in great part counterbalanced by our loss of fellowship with nature. We cannot all have our gardens now, nor our pleasant fields to meditate in at eventide. Then the function of our architecture is, as far as may be, to replace these; to tell us about nature; to possess us with memories of her quietness; to be solemn and full of tenderness, like her, and rich in portraiture of her; full of delicate imagery of the flowers we can no more gather, and of the living creatures now far away from us in their own solitude. If ever you felt or found this in a London street—if ever it furnished you with one serious thought, or one ray of true and gentle pleasure—if there is in your heart a true delight in its grim railings and dark casements, and wasteful finery of shops, and feeble coxcombry of club-houses—it is well: promote the building of more like them. But if they never taught you anything, and never made you happier as you passed beneath them, do not think they have any mysterious goodness nor occult sublimity. Have done with wretched affectation, the futile barbarism, of pretending to enjoy: for as surely as you know that the meadow grass, meshed with fairy rings, is better than the wood pavement, cut into hexagons; and as surely as you know the fresh winds and sunshine of the upland are better than the choke damp of the vault, or the gas-light of the ball-room, you may know, as I told you that you should, that the good architecture, which has life, and truth, and joy in it, is better than the bad architecture, which has death, dishonesty, and vexation of heart in it, from the beginning to end of time.—*The Stones of Venice.*

PARC DE COURCELLES.

THE grounds of this domain slope very much from the point where the waters which descend from the mountain emerge, to the river which runs through the property. The total area is about twenty-five acres. The bounds of the property are concealed by thick clumps of large trees and underwood shrubs. At the crossings of the walks other clumps hide the great sandy spaces, which are always so disagreeable to the sight. A marked centre depression of the surface extends through the entire property to the adjacent meadows, from which the domain is separated by a sunk fence, so that no appearance of an inclosure is presented. The roundish points mark isolated groups or single trees standing on the slopes, while the position of conifers is denoted,

PLAN OF COURCELLES. BY EDOUARD ANDRÉ.

by an asterisk-like mark. The kitchen garden and the flower garden have been laid out behind the dwelling-house, so as not to spoil the general effect of the park landscape; they are joined by a bridge which crosses the stream. The incline on the left bank is very steep and picturesque. The walks on that side run in a cross direction, or length-ways. As the soil is for the most part moist, the trees which have been selected for the plantations are principally deciduous kinds, which do best in cool moist ground. The garden is the property of M. Boivin (Haute Marne), and was laid out by M. Ed. André. The straight lines indicate the points of view.

There is much to admire in this garden, and only one radical fault—the senseless semi-geometrical walks which, as usual in the modern French garden, thrust their ugliness through the fairest parts of the garden. Just look at them where they meet towards the central portion of the grounds! There is no more occasion for this violation of the repose of a private garden than there would be for placing analogous bands of yellow through some charmingly painted landscape.

PUBLIC GARDENS.

KEW GARDENS AND OUR PUBLIC PARKS.

THE management of the Royal Gardens at Kew, as well as of the public parks, is not so simple a matter as some of your correspondents seem to think. It is easy enough to point out defects and to complain that there are details very ill-carried out, but if your correspondents knew the difficulty with which every alteration is made that involves expense, they would be surprised—not that so little has been done, but so much. I perfectly acknowledge the debt which is owing to you, for urging the true principles of gardening, and endeavouring, as you have done, to introduce a system founded on what makes all art good—nature. In public establishments, however, under the control of shifting Governments, it is impossible to act in the same manner, as is easy where the establishment is private and the purse that feeds it large. There may be obvious improvements, which yet cannot be made. The result of what is done may be marred by injudicious economy. The Royal Gardens at Kew are under the management of a gentleman not only of high scientific acquirements, but of excellent knowledge in ornamental detail. Their object has never been either to give lessons in landscape gardening or to produce picturesque effect. Their establishment was principally for a scientific purpose, and they present facilities for study perhaps unequalled in the world. The plants in the conservatory are not arranged in the manner most pleasing to the eye, but the best for instruction, the products of each country being kept, as far as possible, together; and the same principle is maintained in the grounds. In the open air there are great difficulties to contend with. Neither the soil, climate, or atmosphere is well adapted to the growth of what may be most valuable.

The avenue of Cedars has not succeeded, and in place of each Cedar three deciduous trees have been planted, in the hope that one at least may thrive. None of the Conifers seem likely to make fine trees at Kew, though it is necessary there should be specimens of as large a number as is possible, not for ornamental effect but in order that the student may study, the gardener learn, and the amateur choose.

There is another obstacle at Kew. The collection is constantly increasing by gifts or exchanges from all parts of the world, while no increase is made in the resources of the garden.

The management of the Parks is beset by perhaps greater difficulties than are the Royal Gardens at Kew, for the latter are acknowledged to be of great scientific use to the nation at large, while there is a growing indisposition in the House of Commons to vote money for the exclusive enjoyment of Londoners. At the same time there is a zealous opposition to the proper control of the Parks, essential, if they are well kept. The progress of the Bill affecting them, lately introduced by Mr. Ayrton, and the vacillation of the Government points this out. Many, I believe, think that the Parks had better be left to a variety of grave paths, with the occasional grass the "people" choose should not be laid bare; and that they ought to be devoted to the exclusive enjoyment of the lowest class.

The principal improvements which have been of late effected in the Parks are owing to Mr. Cowper Temple, who acted with an independence and liberality that exceptional circumstances enabled him to assume. Had his Italian garden in the Regent's Park been carried up to the Zoological Gardens, a very fine result would have been achieved.

The Office of Works is, in reality, under the control of the

Treasury, which, having to pass, can refuse any of its estimates. The object of the Treasury is naturally to keep down expenditure, and it is seldom the Office of Works is not required to reduce its accounts as far as can be done. When the Army and Navy estimates grow big, the estimates for the Parks and Public Gardens are expected equally to grow small. The whole constitution, too, of the Office of Works is wrong, if it is intended to be an important department of State, and control in any degree the public taste. It is very doubtful, however, that the country wishes for more than is already done, and that any increased expenditure, whatever the result, would not be decidedly unpopular. If I was to venture to give any opinion, I should suggest that the First Commissioner be made independent, that he should move his own estimates, and be alone responsible for what he spent and what he did. It is impossible under our present Parliamentary system to make him a permanent officer, or prevent political considerations, rather than personal fitness, from having great influence in his appointment. He might, I think, be assisted by a permanent board, who would have the professional knowledge he might lack, assist him with their advice, and be responsible for carrying out works begun during one and finished during another Government. But if London is to be regarded only as a huge workshop out of which everyone is to get as fast as possible, and that the principal merit of a Government is to pare down as much as they can, I do not think it likely any Parliament will be found to vote money for the embellishment of London, or a "Minister of Public Taste" be ever appointed.

BRINSLEY MARLAY.

Val de Travers Asphalte Paving Company.—This company announces a dividend of twenty-five shillings per share, being at the rate of fifteen per cent. per annum. At its recent annual meeting, the chairman said a large amount of work had been done during the ten months the company had been established. It had laid down 47,000 yards on footpaths, and had also done considerable extent of private work in laying down floors for stables and in manufactories. The profit for the period mentioned was £16,162 on works executed. It had established subsidiary companies in Great Britain and Ireland. The Scottish Company expected a great deal of work, the Birmingham Company was in active operation, and the Manchester Company had already laid down the asphalté pavement in two streets.

AMERICAN ALOE SPIRIT.

A CORRESPONDENT of the *Tribune*, accompanying the Seward party in their visit to Mexico, thus relates his experience in drinking the liquor of the Mexican Aloe:—"A bottle of the fiery liquid distilled from the mescal plant, otherwise called the 'American aloe,' or 'century' plant, which blossoms in this latitude once a year, instead of once in a hundred, as is commonly believed at the north—called 'mescal,' or 'tekalá'—is sold at the little wayside stands for six and a quarter cents, and it will produce as much drunkenness as a barrel of North-American whisky. I took one drink of it, under the supposition that it was aniseette or some other light liquor, swallowing possibly about an ounce, druggist's measure, before I smelt the burning flesh as the lightning descended my throat. As I set down the glass, my head began to increase in size so rapidly that I saw at once that unless I got outside immediately, the door would be too small to admit of my passing through it. Seizing my hat, which appeared to have become about the size of an ordinary umbrella, I turned it up edgewise, and succeeded by a tight squeeze in passing through the door; the street then appeared funnel-shaped, and I remember an odd fancy that I was to resemble the man who 'went into the big and came out at the little end of the horn.' Curiously enough, my legs decreased in size as my head enlarged, and my last recollection of the affair is that my person resembled a sugar-hogshead walking off on two straws; body I had none. No more tekalá for me, please! The teamsters and muleteers drink this clear, colourless, harmless-looking concentrated lightning with apparent impunity; but a single bottle of it will cause a rebellion among an entire regiment of soldiers, and very likely result in a *pronunciamiento* on the spot."

Carbolic Acid versus Moulds.—A contemporary states that the decomposition of paste may be prevented by adding to it a small quantity of carbolic acid. In the same way, the disagreeable smell which glue often has may be prevented. If a few drops of the solution be added to ink or mucilage, they will not mould. For whitewash, especially when used in cellars and such places, the addition of one ounce of carbolic acid to each gallon will prevent mould and disagreeable odours.

GARDEN STRUCTURES.

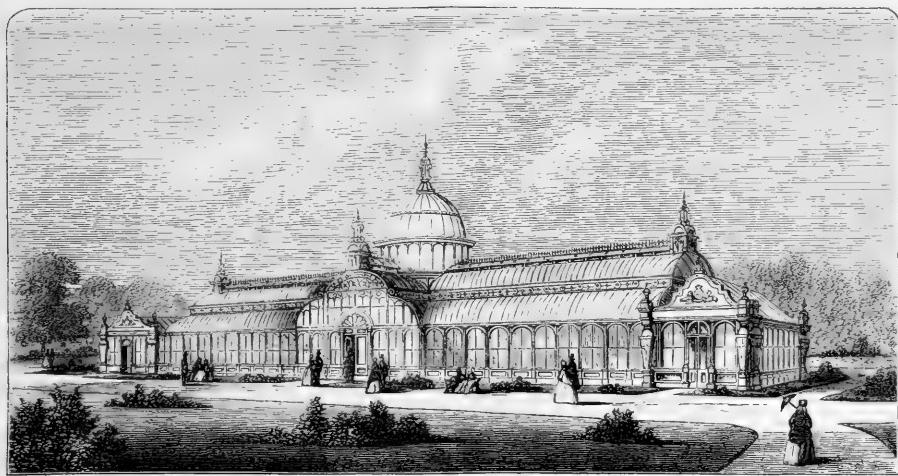

A NEW WINTER GARDEN.

The structure represented by the annexed illustration measures one hundred feet long, thirty feet wide, and twenty-two feet high inside. The foundations on which the iron walls rest, and also the corner columns, are of polished freestone. The central block, in which the principal entrance is placed, extends fifty feet in a northerly direction, and is surmounted by a graceful dome thirty-four feet in height. The wings at either end of the main building, and which are shown in the illustration, measure fifteen feet wide, and are used for waiting and retiring rooms.

At right angles to the main entrance the pathways branch off, and are carried round the interior of the building. These pathways are six feet wide, in the centre of which are placed the hot-water pipes for heating the building, the heat escaping through gratings two feet wide. At either side of the

HEATING BY GAS.

WHEREVER gas is to be had at a reasonable price I am convinced that it is much more economical to heat a greenhouse with it than with an ordinary boiler; and where a large greenhouse is in question it will pay anyone well to make his own gas. Outside a room, seventeen feet by ten feet, and ten feet high, I have a small conservatory, seven feet by three feet, just covering the opening of the window, which has been taken entirely out. Round this little greenhouse runs an inch and a half iron pipe, communicating with a copper boiler outside on the leads. This boiler is broad and shallow, and during the last two winters I have maintained a temperature of 50°, without any fire in the room, by merely lighting the gas under the boiler from eight o'clock at night until the same hour the next morning. Of course the boiler is sheltered from wind and rain. The burner, which is one of those known as a "roarer," is five inches high, and shaped like the chimney of an ordinary paraffin lamp, rising up through a globe. The gas enters the gaspipe and passes to the globular part of the burner, where the pipe is closed, except at an orifice considerably smaller than an ordinary sized pin's head. Through this hole the gas rushes upwards towards the tube or chimney, and before entering it becomes completely mixed with air

Winter Garden at Edinburgh.

gratings mosaic tiles are laid to form the full width of the pathway. A line of ornamental iron tabling, thirty inches wide, is placed along the front, next to the pathway, for the display of plants in pots. The centre of the house is devoted to the culture of large Camellias, Azaleas, Aloes, Palms, and other types of exotic vegetation. At either end of the main portions of the building are placed large mirrors, by means of which plants in bloom are reflected.

Ample ventilation is provided, without which, in a house of this description, all attempts in the way of successful cultivation would end in failure. The ventilators are made to move by means of rods and levers, and the whole of them may be opened, or shut, or regulated in a few minutes. Though this is a great improvement upon old modes of ventilating, yet one now and then finds the old-fashioned plan in operation even in places in which we might expect better things.

The heating apparatus consists of one of Shanks's malleable iron boilers of improved form, so placed that it heats effectively both the winter garden and a range of stove and propagating houses adjoining it. The structure itself, which is a composite one, built of iron and wood, was designed and erected by Messrs. Shanks for Messrs. Downie, Laird, & Laing.

in its passage through the central opening. On applying a light at the top of the chimney, the mixed gas and air unite to form an almost colourless flame, which emits intense heat, accompanied by a "roaring" noise, which, however, paradoxical as it may appear, is very slight.

If the boiler were a large one it would require several such burners, and it should in all cases be as shallow as possible, and well "packed." The products of combustion could of course on a large scale, be carried through the hothouse by the ordinary flue, and thus the whole of the heat would be utilised. There is not the slightest soot produced by these burners, nor smell of any description, even when the gas is impure. I may perhaps here mention that if owners of greenhouses were to place the heating pipes so that they could be regularly black-leaded, they would find a saving in fuel of at least fifteen per cent. after all expenses attending the process were paid.

W. M., Swansea.

Stove for Small Greenhouses.—What is the best stove to heat a small greenhouse?—**QUEERIST.**—[We hear a very good account of Walker's, 58, Oxford Street, Birmingham; but know nothing of it personally. There is also one advertised by a manufacturer at Hounslow, of which we have had favourable reports. The point requiring attention is to keep the gas from escaping into the house, and thus injuring the plants. This remark, as a matter of course, does not apply to cases in which the gas is merely used to heat a boiler furnished with hot-water pipes.]

THE KITCHEN GARDEN.

THE ASPARAGUS CULTURE OF THE ANCIENTS.

With reference to the inquiries on p. 385, on this subject, the following may furnish the information which your correspondent requires:—

CATO "DE RE RUSTICA," CHAP. CLXI.

Dig up ground that is moist and rich: after it has been dug, make beds, so as to be able to hoe and weed, right and left, without treading on it. To this end make spaces half a foot broad betwixt them in every direction, and then sow. With a stake deposit two or three seeds at a time in line, and with the same stake cover the hole with earth. Afterwards scatter manure over the beds. After the vernal equinox, where it (the crop?) shall have sprung up, frequently clear the weeds,* and take care that the plant be not plucked up along with them. In the year after sowing, cover it with litter during winter, that it may not be pinched or nipped. Then in early spring uncover the beds, hoe and weed them. Three years after sowing, burn^t the soil or surface at the beginning of spring. After this, do not hoe before the asparagus has sprung up, lest in hoeing you should injure the roots. In the third or fourth year gather the asparagus close to the root; for if you break it off, sprouts will arise, and die off. You may pull continually, till you see the plants go to seed. Beware of breaking off the shoots. Take care to lay on as much sheep manure as possible; it is best for this purpose. Other manure engenders weeds.*

Elsewhere (chap. vi. s. 3) Cato recommends sowing the wild asparagus (*corrua*) in a reed-bed, because it is dug and burned and shady at times, and so suitable for the wild asparagus, "from which come the cultivated sorts" (*unde asparagi faint.*).

It would seem that the "*corrua*" was what Columella refers to in his line,—

"Et bacca asparagi spinosa proslit herbā,"

one of a prickly species *acutifolius*, *aphyllus*, and *horridus*, which occur in Greece, Italy, and Sicily. (See Dr. Daubeny's "Lecture on Roman Husbandry," p. 250.)

The doctor adds: "That the Romans cultivated asparagus for the table appears from Pliny, who calls it *altilis* (fatted), but it does not appear whether what is intended by Columella in the verse quoted is the latter, or the prickly '*corrua*'. Dr. Sibthorpe, however, in his MS. notes on '*Dioscorides*' adds that the young shoots of the Asparagus *acutifolius*, and perhaps also *A. aphylus*, are boiled and eaten in Greece, as the garden asparagus is with us." (*Ibid.* p. 251.)

Pliny's notices of asparagus are to be found in his *Nat. Hist.* xix. 8 and xix. 4. Juvenal, in a description of a dinner to a friend, supplied from the produce of his farm, mentions "mountain asparagus," "*posito quos legit villicus fuso,*" xii. 69.

"Asparagus beside,

Flick'd by my baillie's plain but cleanly bride;
Who, when the wheel's domestic task is o'er,
Culls on the hills my vegetable store."—*Hodgson's Translation.*

Suetonius, in his Life of Augustus (c. 87) says that that emperor was very fond of it, and that there was a Roman proverb of things done with haste:—"Quicker than the cookery of asparagus."

Columella (xi. iii. 43-47) goes over much the same ground as Cato, with a few additional directions. JAMES DAVIES, M.A.

POTATOES.

POTATO planting-time has again arrived, and with it we must take into consideration what sorts we shall plant. But why do people so persistently leave the ordering of their seed tubers until the spring, instead of getting them in the autumn? For small gardens a few shallow boxes would hold all the "seed" that is needed, and but little care is required to keep it from frost; then the purchaser has this advantage, that when his sets begin to grow he can expose them to light and air, and thus secure for planting tubers in the best possible condition. But if "seed" orders are left till the spring, what is the difference? Why this, that probably the tubers supplied have already pushed shoots which have been rubbed off, thus weakening the tuber, or else, if the shoots remain on, then the bulk in measurement is reduced to the detriment of the purchaser. Some early kidneys must be secured. In this particular section we have

* *The seeds.*—The Latin word here is "setae," which more strictly means "grafts" or "staplings." It may indeed never bear fruit.

^t *Burn the soil or surface.*—The Roman author merely says *incendere*—burn, by which I conclude he means to refer to the practice of burning of the soil and the plants on its surface, to which Virgil alludes in Georgic I. 84, &c., for the purpose of giving back to the soil the essential ingredients of its decomposed vegetable matter, and of correcting sourness of soil, or perhaps of improving soil that is over-moist and too adhesive. (See Dr. Daubeny's "Lecture on Roman Husbandry," pp. 92, 93.)

in the matter of earliness as yet made no great advance, but in regard to both quality and cropping there is decided improvement. Myatt's Ashleaf, as a first market kidney, still holds its place, but private gardeners adhere to the Royal Ashton, Veitch's Improved Ashleaf, Alna, Gloucester Kidney, and Harry Kidney, all of which are certainly good. In succession, then, let us take Webb's Imperial, Sutton's King of Potatoes and King of Flukes. And for long keeping kinds, such sorts as Yorkshire Hero, Rixton Pippin, Belgian Kidney, and Yorkshire Hybrid, any and all of these are fit for any gentleman's table, and may be recommended with perfect confidence. With respect to round kinds there is not so wide a choice, but still enough that are really first rate from which to select. For earliness and quality combined none will be found to exceed Turner's Union and Hogg's Goldstream; then follow with Scotch Blue, Early Emperor, alias Carter's Main Crop (for it is the same thing), and Onwards; or, if that is not obtainable, take Dalmahey, which is the best of all the Regent section. To succeed these for a late crop, take Victoria, Alexandra, and Wellington, these latter being not only the best of croppers, but also excellent late keepers.

If tubers for exhibition are wanted, select them from among those just named, which will furnish some of the handsomest obtainable for that purpose; and if it is desirable to secure a sound, healthy crop of moderate-sized tubers rather than a heavy crop of large roots, it will be found that judges will invariably award prizes to samples that are clean and handsome rather than coarse.

If the soil be naturally free, and the situation warm; planting should commence at once; but if the soil be stiff, and still full of moisture, then wait patiently a week or two longer until the dry winds of March have freed the earth from its superabundant wet. If the soil be deeply cultivated, and the application of manure be early, dry situations will invariably produce sounder and better flavoured tubers than moist soil, howsoever good otherwise it may be. Lime applied to the soil before the planting, and in a dry slackened state, not only sweetens the earth, but adds materially to the quality of the tuber. It is an exceedingly cheap manure, and should be much more generally used.

A. D.

SINGULAR FREAK OF A POTATO.

SEVERAL potatoes have been sent to us in which a new potato had formed within an old one, and, by its expansion in growing, broken the potato apart. It is either the case that the potato has deeply seated dormant eyes, or that it possesses the power, under favourable circumstances, of forming buds where none previously existed. Dr. Hexamer has found that potatoes which were pared and every visible trace of eyes removed, would sometimes produce shoots and tubers.

Abnormal Potato.

resistance towards the centre of the potato than it did in pushing towards the circumference.—*American Agriculturist.*

OUGHT I TO COMPETE?

AFTER marking out my seed order, I saw that several seedsmen had offered special prizes for vegetables at the forthcoming show of the Royal Horticultural Society. I am young and enthusiastic, and pride myself that I can grow vegetables; and I also have a good garden of eight acres to grow them in. On seeing the announcement my pulse started beating more rapidly than usual, as I thought, Here is a chance to exhibit to the world the fruits of my cultural abilities, and perhaps gain a prize that will cover my expenses to Birmingham; but on reading the conditions I find I have not ordered a single thing that the above-named seedsmen insist on having. Well, I am in no way indebted to my present seedsmen, except it be for his honesty in supplying me with seeds good and true before the law attempted to force him to do it, and his strict attention to small orders for things

wanted in a hurry. I am at liberty to deal where I choose, and my employer will not look at the details of my garden account provided the grand total is not too high; why not then change my seedsmen, and procure new peas and cucumbers direct from the growers? But there is another consideration: there are required, in the first place, six varieties of peas to be exhibited all at once. I must make two sowings at least of each to have a chance of getting a dish at the right time, as most of the sorts are strange to me; and all varieties of peas do not take exactly the same length of time to grow. This would take up a good bit of my garden, as well as time and money, and it would also be a radical change for me, who only grow two kinds to supply the table from the middle of May to November with good marrow peas, which are Little Gem for early and late, and Veitch's Perfection for general mid-season crops. There may be better peas than these, but on consideration I think I had better not discard my old and tried friends till I am sure one or two of the new ones are better. I do not want many sorts—they do not cook well mixed. I must have marrows when they are to be had, and I cannot waste my ground with tall-growing kinds. These thoughts make me decide not to try for the Challenge Cup.

But what about the cucumbers? I grow cucumbers successfully, a week has never passed for the last three years without my having at least half a dozen to cut; but here again I have an old and tried friend staring me in the face, one that would not be noticed on an exhibition table, but which is always ready for my employer's table when wanted, and its flavour is pronounced excellent. (By the bye, why do not judges taste cucumbers? is it supposed they are only grown to be looked at? they are grown here to be eaten as the most *recherché* of second-course vegetables.) So, taking all things into consideration, I have made up my mind, for this season at least, to stick to my old and tried friends—peas, cucumber, and seedsmen.

J. WILLIAMS, Chippingham, Wilts.

TRUFFLE CULTURE AT WELBECK.

WHEN I first came to Welbeck in 1837, no truffles were ever found or heard of in the locality, but they afterwards appeared in a young oak wood near the pleasure-ground, and close by the lake. The oaks in this wood had a growth of about twenty years, and I thought, from the nature of the soil, that truffles were likely to grow in it, if I could manage to introduce them. I had, therefore, the over-ripe truffles and the parings of the skins of others from the kitchen planted there for a series of years, and was agreeably surprised one autumn by one of the men bringing me a fine truffle that he had found when mowing the grass near the verge of the plantation. This tuber had grown near the surface, for he had cut a small portion of the top off with the scythe. This discovery was amply rewarded by the then Duke of Portland, for the man got a gratuity, and was ordered to point out the place, which was not disturbed afterwards for a year or two. The oak leaves were not raked off, but allowed to rot on the surface, and afterwards I found plenty of truffles every autumn, not by a dozen or two, but sometimes as many as six pounds at a time, when wanted for particular purposes. I sent once a tuber of the weight of six ounces to the late Dr. Lindley, who wrote me back that it was a very fine specimen of the true truffle, *Tuber astivum*. From not having truffle dogs to scent out the ripe ones, a great many young or only half-grown tubers were taken up every autumn, which was, of course, against the supply. The squirrels were the best purveyors for finding the tubers; for as soon as they began to ripen, Mr. Squirrel scented them out, and, if not disturbed, scratched down to the truffle, and had a good feast on it. The soil of the oak wood which produced these truffles was of a calcareous nature, and had evidently been originally excavated from the bottom of the lake, for it was full of small fresh-water shells. This plantation produced truffles every year till some alterations in the pleasure-grounds were planned, when all the young oaks were cut down, and the ground raised four feet higher, which, of course, settled all the interesting colony.—William Tillary.

NEW KIND OF SEAKALE.

"For a century or more," says Mr. W. Prestoe, in the *Field*, "we have been plodding on with little or no improvement in the varieties of seakale which we cultivate. Ten or twelve years ago, I found one plant pushing much earlier than any of the others, and, on more minutely examining it, it proved to be distinct from the old purple-crowned variety, and much more robust. It also came into bloom much earlier. I carefully saved all the seed, and in the following April sowed it in the usual way. All went on satisfactorily, the produce being strong plants fit for forcing the next season. From this first batch of seedlings I selected a few of the very strongest for seed another season. Thus I went on until I could readily perceive

a new character in the plant altogether. It became unusually large, of a pink colour when blanched, and a fortnight earlier than the old sort. Having thus determined on my selection, I again saved all the seed I could, and from this stock I again selected twelve of the strongest. From this I sowed enough seed to sow a quarter of an acre of ground. I next made choice of a very poor piece of gravelly land in an open field, to which not one ounce of manure was given. I sowed the seed about the middle of last April. With this I send you a fair sample of the plants. This is not all. I cut excellent seakale fit for any nobleman's table in February, without artificial heat of any kind; no forcing whatever, but simply cutting the old plants to pieces, with three or four inches of root; placing them in a trench—just such a trench as one would dig for celery—ranging the "sets" regularly in the bottom, with a few leaves and a little packing fern as a blanching material. With the sample of plants I also send a sample of the kale. You will perceive it is pushing up by bloom, a proof it ought to have been cut for table a fortnight ago. I think I may now lay claim to a new and distinct early variety of seakale, in which there is just the same difference as is to be found between the old Tobolsk rhubarb of forty years ago and the Victoria or Prince Albert rhubarb of the present day. One thing is certain; I have no need in future of using any artificial heat for seakale after January."

[This communication was accompanied by a parcel of seakale of fine quality and size.—Ed.]

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Long Asparagus.—I would suggest that when you see asparagus grown up eighteen inches or two feet, do not let it—for that reason at least—be wasted; snap it off (do not cut it, but snap it off as low down as it will snap), cut it into half-inch lengths, and treat it as you do peas, boil it and serve it with melted butter; and if you do not find it by far the finest vegetable you ever tasted, why, then put no more faith in me—C. F. W.

Pea Growing.—My method of growing peas may not perhaps be altogether without interest, especially as in this neighbourhood gentlemen who have gardens wonder how my peas always do so well, and never seem affected by dry weather. I dig a trench, and in this trench lay a good coating of manure; this is then dug into the trench and levelled with the spade. The peas are then put in one by one, at about two and half inches apart, the row being the width of the spade; this is rather tedious, but well repays the labour. They are then covered with sifted ashes, and over that the leeward side of the trench is drawn over, covering the peas about three inches. They are thus protected by the ridge until high enough to have sticks, and all through the winter's frost and snow the pea never bleaches or withers.—Amateur.

Planting Early Potatoes.—I would warn intending planters of this kind of vegetable to defer planting until from the first to the second week in April. Many plant early, thinking to be before their neighbours. Never was a greater mistake. The proper plan is to lay out singly in a late vineyard about Christmas, or in any outhouse protected from frost. By planting-time they will have made fine strong green shoots, when they should be taken up carefully, putting them into drills about three inches deep, when they go on growing at once, and will all be fit for lifting at the same time.—Delta.

Earliness of the Season in Dorsetshire.—According to your article on Market Gardening about London, page 365, I find—although this is a cold climate for a southern county—I have produce more advanced than I should have thought: for instance, I eat asparagus to-day four inches long; and for the last three weeks have pulled rhubarb—Dancer's Early Scarlet and Linnaeus. Both these are grown in the open air, without any protection beyond that afforded by a walled garden. I have not heard that any others are so forward in this neighbourhood. The asparagus beds were made and planted last year with three-year-old plants, and are composed of sea sand and horse dung to a depth of three feet, with a top dressing of sea weed. The rhubarb bed is composed of sea sand, horse, cow, and pig manure.—JAMES KEE, Portville, Bridport.

How to grow fine Parsley.—Sow it towards the end of August. Let the soil be comparatively poor but well drained; but if circumstances prevent such selection, choose the ground which comes nearest to it. It may be sown either in lines where it is to remain, or in seed beds; but in any case it must be transplanted, for parsley does much better, and lasts longer in that way than by the usual mode. Spring-sown parsley runs to seed much sooner than that sown in autumn. It will be fit to transplant in March, and should then be put in whatever positions you wish it to remain. The plants so transplanted will be found excellent to pop into pots and boxes for the winter, as is the rule in gardens where a winter supply of parsley is indispensable in all weathers, or for any other purposes for which parsley is used. Edgings of parsley near a dry walk or alley are desirable for the convenience of picking when the ground is sloppy in winter.

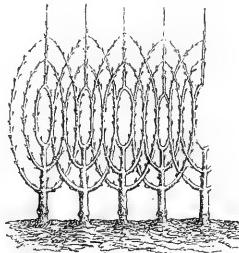

Stringing the Beans.—“What do you want a needle and thread for, Bridget?” “Well, mum, cook has just towld me to string the beans, an’ sure an’ I want a neydie an’ thrid for that.”

THE PROPAGATOR.

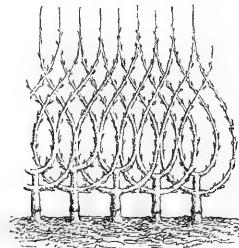

THE ART OF GRAFTING.

(Continued from page 387.)

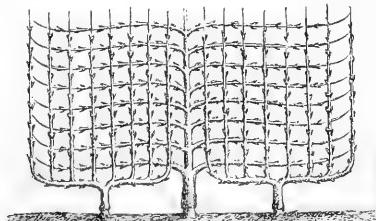

APPROACH GRAFTING IN FIGURE TRAINING.—In order to show the happy results of grafting by approach, we have here figured some specimens of espaliers trained in the garden of M. Nallet, at Brunoy. The trainer, M. Forest, has employed grafting either to complete their construction or to preserve the equilibrium of growth. MM. Van Hulle and Burvenich described these trees, in 1867, in their reports to the Belgian

Government. Annexed is a representation of an espalier of Pear trees, formed with small palmettes, the branches of which interlace and touch each other. The trees are grafted at the points of contact in the centre of the design, where the branches touch back to back, and not where they cross and diverge. The slight curvature of the branches, which gives each tree an elliptical outline, is favourable to the development of fruiting branches; the extremities are inarched into the leading shoot formed by the union of the branches of the third series. The next illustration is a variety of the preced-

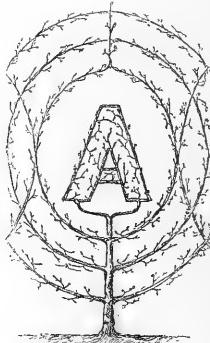

ing arrangement, and a preferable one. It requires only palmettes of two series, and the sinuous form of the branches permits long pruning, and maintains the fruit spurs regular. The leading shoots are crossed in lozenge form, and are grafted by approach at the top. This charming design, which is less

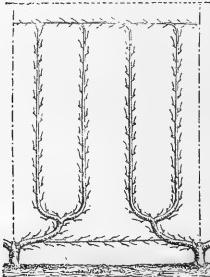

complicated than it appears, is produced with regularity if the outline has been previously traced with switches fastened to the trellis. In the third illustration a palmette and two

chandeliers are united and support each other mutually. The extremities of the branches of the horizontal palmette are inarched into the outer branches of the chandeliers. It is better not to graft the branches where they cross each other. A group like this should be grown in the open ground, and not against a wall. The next figure represents a palmette-chandelier, of which the branches—following a regular curve and

grafted together at the ends—represent a target. In the centre, M. Forest has formed a letter by approach grafting. A row of six such trees exhibits the name of M. Nallet. In designs of this kind we prefer that the letters should take the most prominent part and not be merely accessory; accordingly we have formed the name of our establishment in one of our borders. Each Pear tree forms a letter, so that in case of damage the injury can be more speedily repaired than in the case of a tree which forms several letters. The different modes of grafting by approach are useful here. A similar design has been formed with Peach trees on a wall. The fruit gardens of M. Alexis Lepère, at Montreuil, and of others, contain handsome specimens of trees joined by approach grafting, and representing inscriptions or designs accurately completed, according to the method of M. F. Simon, an amateur at Crecy-en-Brie. The accompanying representation

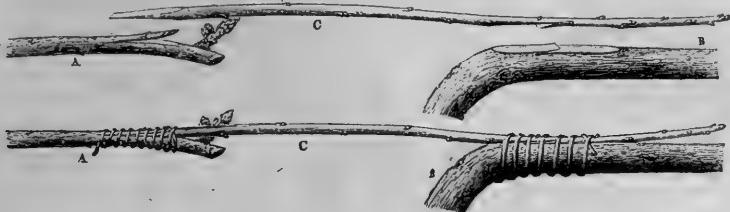

shows two halves of Peach trees trained in the form of double U, or a small four-branched chandelier by means of their sub-division the arms of which are united at their extremities by means of approach grafting. We have also proved the good effect of approach grafting in forming winged pyramids, vases, harps, &c., either isolated or on trellises in the fruit garden of M. A. Mas, pomologist, of Bourg, and in the orchard of the Agricultural School, at Saulsarie (Ain), made by Verrier. The single cordon (improperly termed horizontal on sloping grounds), which is especially adapted to the Apple tree, should have the trees which compose it grafted one upon another. The end of each is cut with a sloping or splice cut and inarched or inserted under the bark of the next tree at the bend. A continuous even line of small trees is thus obtained. It may happen that from want of vigour, or in consequence of

an accident, one tree cannot reach its neighbour. In such a case we have recourse to the method of lengthening or joining shown in the accompanying figures, which were communicated

to us in 1860 by M. Jules Ricaud, of Beaune. The subject (A) not being long enough to reach its neighbour (B), we take a well-grown branch (C), of the current year if we operate in August, and of the preceding year if we graft in April. The base of this is cut with a double slope, and is introduced into the incision on A, which penetrates the alburnum by the process

it. (The jury, after some hesitation, said that on the evidence they could not say otherwise.) Then were they satisfied that the defendant was aware of it? (The jury said, "Decidedly not.") Then, thirdly, if not, was it so notorious that he ought to have known it? (The jury said, "Certainly not.") Fourthly, was the gardener the servant of the defendant in the matter, or of the jobbing gardener, who paid him? (The jury said, "The jobbing gardener's.") Fifthly, were there any orders given either by the defendant or by his authority for doing the act complained of? Most people, the Lord Chief Justice observed, had a notion that a wife had her husband's authority; but that was only so as matter of law in the ordinary affairs of household. As to other matters, an express or implied authority, in fact, was necessary; and certainly there was no legal authority to cut down his trees. Then the husband would not be responsible for the act of his wife without his authority. In the present case there was not only no evidence of authority to cut down the tree, but it appeared rather that it was cut down against his will. However, what was the opinion of the jury on the point? (The jury consulted together and said that the tree was cut down without his authority.) Next, were the yew cuttings placed on the rubbish heap by the authority of the defendant or any authorised agent of his? (The jury said they were not satisfied of this). Upon these findings the Lord Chief Justice

of side cleft grafting. The other extremity is cut with a notch in the part which will bear upon the other tree, in which a corresponding cutting is made. The parts, being fitted into each other, are bandaged and covered with grafting wax. The method of inarching might also be used here with equal advantage. —C. Baltet's "L'Art de Greffer."

(To be continued.)

L. A. W.

Poisoning by Means of Yew Tree Clippings.—A case of this kind was tried at Maidstone the other day. The plaintiff and defendant were two gentlemen who live at Lewisham. Their premises adjoin, and are only separated by a kind of lane or passage. In this lane, against the fence of the plaintiff, was a rubbish heap, on which garden cuttings, dung, and other refuse were thrown. On the defendant's premises, near his fence, was a yew tree, which, in the autumn of 1870, was clipped, and the cuttings were thrown by his gardeners on to the rubbish heap against the plaintiff's fence. The plaintiff observed the heap gradually rising to the height of his fence, and complained of it, thinking that the defendant ought to cast his rubbish against his own fence. However, the heap was continued, and a day or two afterwards two colts of the plaintiff's, which were in a paddock bounded by the lane, put their heads over the fence and ate of the yew tree cuttings and were killed. The plaintiff wrote to the defendant claiming compensation, and setting the value of the colts at £1,000, but offering to take £500 if paid within a week. The defendant, however, denied his responsibility, and the claim was resisted. In the plaintiff's evidence it was stated that the defendant first raised the rubbish heap, and it was admitted that it was well known that yew tree cuttings would poison horses or cattle. A few days before the accident the plaintiff wrote complaining of garden cuttings being put upon the rubbish heap. He did not, he said, notice yew tree cuttings, but he admitted that he was well acquainted with the defendant's garden, in which the yew tree was. It appeared that the defendant had employed a jobbing gardener at Sydenham to put his place to rights, and two men were sent down for the purpose, who had orders from both the defendant and his wife. The latter directed them to cut the yew tree down, though the defendant did not wish it, and when his back was turned the lady gave the order, and it was cut down and the cuttings were thrown into the lane on the rubbish heap. It was submitted on the part of the defendant that there was no evidence of authority to cut the tree down, and even if there was, there was no evidence of negligence on the part of the defendant, as both parties were equally cognizant of the nature of yew tree cuttings. It was urged that it was very hard that a man should have his yew tree cut down by his wife's order against his own will, and that then he should be held liable for consequences which could no more be foreseen by one party than the other. The Lord Chief Justice, in summing up the case to the jury, said it was one of some novelty, and would involve various questions. First, were yew tree cuttings dangerous and poisonous to cattle and horses? He supposed they would not doubt

said the verdict must be for the defendant, but it might be well that the jury should say what they thought the value of the colts was. (The jury said £75.) The verdict was entered for the defendant.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

PRIVATE GARDENS.

Indoor Plant Department.—In conservatories, which are now as gay as they will be at any time during the whole year, and in which the young shoots of many of the inmates are pushing freely into growth, cold draughts are carefully guarded against; for should such be allowed to pervade these structures, what would become of the many cool Orchids now in bloom in them, together with Medinillas, Franciscus, Begonias, Eschynanthus, Eranthemums, Thrysacanthus, early Gloxinias, Coleus, and other introductions from warmer houses? Specimen Boronias, Chorozemas, Genethylis, Heaths, &c., now add to the beauty of conservatories, whilst specimens of other things are being forced, or have their blooming season retarded by removal to houses with a north aspect. Balsams and Closias, of different sorts, for early flowering, are shifted before they get pot-bound, using for them an open rich soil. Coleus, for indoor work, are also kept shifted, and pinched to keep them shapely; they enjoy being plunged in bottom heat. Mignonette is, in some cases, neatly trained on wire trellises. Both Show and Fancy Pelargoniums for early flowering get a little manure water, applying more to the weaker, than stronger varieties. To those for later flowering abundant ventilation is given. Camellias and other plants done flowering and pushing afresh, are syringed regularly, sufficiently early in the afternoons to admit of their foliage becoming dry before night. Stove plants which are syringed freely, enjoy a moist atmosphere. Stephanotis floribunda, in some places is in flower; in others it is now in full growth. It requires plenty of moisture, and whether grown in pots or borders, on pot trellises or on wires along the rafters, it must be regularly tied and shifted. Allamandas, Clerodendrons, Bongainvilles, and Dipladenias require similar treatment, and have the benefit of being plunged in bottom heat. Ardisias, Gardemias, Durantas, Lagerstroemias, Plumbagos, Rondeletias, &c., are well syringed morning and afternoon; an operation which keeps down insects. Poinsettias that flowered early and now breaking, are pruned back to within a few eyes of the base, and started afresh; in some instances cuttings are only retained, the old plants being thrown away. Among Orchids, Calanthes, Odontoglossums, Caelogyne, and others belonging to the Mexican house, are still being reported, top-dressed, and placed on new blocks where necessary. Water at the root is as yet given only sparingly. Ferns are allowed

plenty of water, and the greenhouse and hardy kinds are being reported.

Pits and Frames.—The propagation of bedding plants now requires particular attention; plants of Coleus, Alaternthers, and others are being subjected to a high and moist temperature in order to induce them to yield cuttings, which are struck and potted off singly in great quantities. Centaureas, Lobelias, Petunias, &c., are being now sown in heat, and as soon as fit to handle are pricked off into pots, pans, or boxes. Lillums are kept near the glass in cold frames; no water is, however, given them until they appear above the surface. Sempervivums and many other hardy things kept during winter in cold frames and houses are being placed outside. Calceolarias from cuttings kept in frames are now lifted and replanted in good mould further apart. In forcing pits regular supplies of Lily of the Valley, Spireas, Dielytras, Roses, Azaleas, Kalmias, Callas, Deutzias, Lilacs, Cyrtisus, &c., are being kept up for the decoration of the conservatory.

Flower Garden and Shrubbery.—Beds of spring flowers, which are kept neat and clean, now prove very attractive. Borders in front of shrubberies are being manured and dug, and where hardy edgings, such as Stachys lanata, Cerastium, variegated Polemonium, Sempervivums, are to be used, they are lifted, divided, and replanted. Lawns and grass everywhere are now being mown. Evergreen shrubs still continue to be lifted and transplanted (though the present is not nearly so good a time for that operation as September), and large plants intended for removing next season are having their roots pruned. Pruning of roses, evergreen, and other shrubs is being proceeded with. Where conifers throw up more than one leader, the contending ones are being removed, leaving that which is most promising.

Indoor Fruit Department.—In the case of Pines, new tan-beds are being prepared for plunging those about to be potted. From those fruiting suckers are being removed, their ends dressed with a sharp knife, and potted. Smooth Cayennes done fruiting, have their leaves shortened to induce them to produce suckers. Vine shoots are being thinned and tied, and a steady moist temperature maintained. Peach shoots are being tied in, and superfluous ones removed. The syringe is freely used amongst the foliage. A rather low and equable temperature is maintained until the stoning process is over, a kind of treatment which is especially applicable to Cherries. Figs are liberally watered both at the root and overhead. Strawberries in bearing are kept rather dry, and too many are never allowed to ripen on one plant. A regular succession is kept up, by which means there is never any scarcity. Cucumber and Melon beds have their heat maintained by means of renewed linings. Succession crops are being sown, and when the plants have formed two rough leaves they are potted off singly, and kept near the glass in a warm, moist pit or frame. Beds in which bearing Cucumbers have been kept throughout the winter, are being renewed and furnished afresh with young plants. French Beans are being sown, and those about to flower earthed up. They are frequently syringed. Tomatoes are being potted off, and others sown. Chilies are sown in heat. Celery is pricked off into boxes of rich mould. Asparagus and Seakale continue to be forced. Potatoes in frames have plenty of air, and are earthed up as they require it.

Outdoor Fruit and Kitchen Garden Departments.—Trees on walls are being protected. A dusting of lime over fruit trees and bushes is found to be beneficial where birds, insects, and moss are troublesome. Cauliflowers are lifted with good balls, and planted in rows two feet apart each way. A little protection at night, if practicable, is of great benefit to them. Small sowings are also being made. Savoys and Brussels Sprouts are sown to succeed those put in in the first of the month. Of Borecole or Kale main sowings are made. Parsley is being sown in rich soil, in lines along the sides of plots of ground, for which it acts as an edging. Radishes and Lettuces are sown as required. Peas are being sown in succession in drills three inches deep; those that have come up a little have some earth drawn to them and are being staked. Where stakes are scarce, the dwarf kinds of Peas are sown. Peas are also sown in boxes in heat, for cutting when three inches high for use in soups. Between lines of Peas early Cabbages are being planted one foot apart, so that when too close every alternate one is drawn, leaving the others two feet apart for hearting. In ground where "clubbing" prevails, the roots are dipped in a mixture of earth, soot, and water, about the consistency of paint. Potatoes are being planted, excepting in cold or heavy soils. Main crops of Parsnips and Leeks are being sown; also of Onions where not already done. Dustings of lime, or finely sifted coal ashes scattered over the surface of the ground, act as good preventives of slugs and snails. The hoe is used freely amongst growing crops of all sorts.

NURSERIES.

Indoor Department.—Propagating constitutes the chief work in nurseries at present. Clematises are being struck from eyes and short jointed cuttings containing two eyes. Dahlia roots, placed in heat, are now furnishing young shoots in abundance, which are taken off and struck, and as soon as they are rooted they are potted off singly; when fairly established they are placed in a cooler house. Hollyhocks are started in pots in heat, the shoots slipped off with a heel and struck. Young Dracemas from pieces of the stem and roots are being potted and kept close. Allamandas, Clerodendrons, Dipladenias, &c., are being raised from cuttings, to which is attached a "heel" of the old wood. Begonias are being increased by laying good, firm, well-matured, healthy leaves on the surface of a pan or pot of silver sand, and pegging them down; the main ribs being first broken to encourage the production of young shoots. Heaths, Epacries, Boronias, Diasmas, and many other hard-wooded greenhouse plants, likewise conifers, such as Cypress, propagated in autumn are in some cases kept in gentle heat, and in others placed in cold frames covered with bell or hand glasses. When there is time to spare, and the plants are well rooted, they are potted singly, and kept for a time under hand lights in warm pits. Ferns are raised from spores sown in pots and just pressed gently in a fine surface, over which a piece of glass is placed, or the pots are kept in close frames within the propagating pit. Such as have covered the surface, of their pots with young plants are cut into pieces about half an inch square, and these are planted in small pots, or in pans, keeping them about an inch apart. Farther advanced seedling ferns are being potted, and kept in a warm, close, and equable temperature. Hardy ferns are being potted. Some of the finer sorts of Lilies are being put into small pots, and kept without water until they appear above the surface, when they are plunged in coco-nut fibre in cold frames, protected merely from frost. Grafting of evergreen shrubs, such as Yews, Cypress, Hollies, &c., is being carried out; the more tender varieties being worked on the harder kinds of stocks; they are kept in a close gentle heat and shaded. Rhododendron seed is being sown; a layer of damp moss is placed on the surface to prevent evaporation. Young hybrid varieties are being potted off. Grafting of Roses and Rhododendrons is likewise being proceeded with.

Outdoor Department.—Herbaceous plants in pots continue to be divided and potted singly. Primulas from seed are being potted off. Hollyhocks from seed are transplanted from their seed beds into borders. Carnations are being transferred from pots into beds. Foxgloves in seed beds are being transplanted into lines a few inches apart. Phloxes, Pentstemons, and other choice hardy plants wintered under cover, are now being moved to beds of coal ashes out of doors. Young Figs in pots are kept in cold frames uncovered. Vines in pots are being cut back and taken indoors. In the open ground, Roses, both standards and stocks, are being laid in in lines. Deciduous and evergreen trees are likewise being laid in; and the training of fruit trees is now receiving attention.

MARKET GARDENS.

No sooner is a piece of ground cleared of one crop than it is heavily manured, dug, and at once prepared for another. Rhubarb is now plentiful out of doors. A variety named Champagne is that most used, on account of its fine deep red colour. The Linnaea is also much grown because of its productiveness, and the Victoria, which is a late variety. Seakale, like Rhubarb, is now also obtained from the open ground. Seed of it is now being sown thickly on four-foot beds, and plants of last year's sowing are being transplanted in lines a foot apart each way. Celery ground, as it becomes clear of its crop, is levelled, manured, dug, and planted with Lettices, Cauliflowers, &c. Strawberry plantations are still being made; Stirling Castle seems to be the favourite early variety. Borders in warm situations are being prepared for French Beans, which, however, will not be sown for some weeks yet. Globe Artichoke plantations are still being made, on deeply-worked well-manured ground. Peas are sown in succession in single lines, which, in the case of dwarf varieties, are about three feet apart. Taller varieties are put in at considerable distances apart, so as to allow space between the lines for crops requiring some little protection. A second, main crop of Beans is now sown, and plantations of Horse-radish made, the pieces of roots being set twelve inches apart, and fifteen inches deep. The produce is generally allowed to remain undisturbed till the second year after planting. Skirret, Salsify, and Scorzonera are sown in small quantities for early use, but main crops not yet, as they are apt when sown early to run to seed. Successional sowings of Radishes are regularly made, in many cases without covering the beds with litter. Those above ground have the litter raked off them during the daytime with a

wooden-toothed rako. Tomatoes, Vegetable Marrows, Cucumbers, Celery, &c., are raised in great quantities in hot frames. Frames containing Lettuces and other crops are being held in readiness for their reception, and trenches are dug in the ground, filled with hot dung, over which some light mould is placed, in which Marrows are to be planted.

While we write (March 21st) snow is falling heavily, destroying the hopes which the brilliant weather of the last few weeks was calculated to inspire, and doubtless rendering considerable modification necessary as regards many of the operations named above. Half-hardy plants especially will require increased attention.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

An interesting meeting of this Society was held last Wednesday, in the Conservatory at South Kensington. The weather was fine though cold, and there was a grand display of spring-flowering plants. Hyacinths, as heretofore, formed the principal feature of the exhibition, which was well supported by Messrs. Veitch, who furnished no fewer than 275 plants of extremely well-grown Hyacinths. The same exhibitor took the first prize for eighteen distinct kinds, which consisted of Von Schiller, Blanche Formidable, Cavignac, Vanbrak, Haydu, Macanlay, De Candolle, Blondin, Solfaterra, Charles Dickens, Lord Byron, Grandour a Merville, Bloomsberg, La Grandeuse, Koh-i-Noor, King of the Blues, Ids, and Lady Palmerston. Another fine collection of Hyacinths, consisting of 114 plants in excellent condition, was staged by Messrs. Paul, of Waltham Cross.

The amateurs' class contained plants in every way commendable, being distinct in colour and kind, and well grown. Several new Hyacinths were exhibited, some of them distinct in colour; amongst them Chapais d'Orange, Lady Mayo, Excelsior, Prince de Naples, and l'Ornement de Rosa, are pink of different shades; Sylvia, J. H. Veens, Mrs. Radcliffe, are pale blues; Lila Major, Tricolor, Lord Mayo, and Yescho, are dark coloured ones. These were contributed by Messrs. Veitch, Mr. W. Paul, and Mr. Douglas, gardener to F. Whitbourne, Esq., Loxford Hall, Ilford.

Of Tulips over seventy pots were staged by Messrs. Veitch, who carried off the first prize with Pride of Haarlem, Rouge Luisante, Brutus, Rose Miniature, Due de Holstein, and Fabiola. Some fine Tulips were also shown by amateurs, more especially by Mr. Rowe, gardener to Mrs. Lewis, Roehampton, who received the first prize.

About fifty pots of well-blown plants of Narcissi were staged by Messrs. Veitch. There was likewise exhibited a collection of cut blooms of Narcissi, of more interest, perhaps, to botanists than to horticulturists; but still valuable to the latter as types of what they grow in that way, in which there is generally much confusion.

Oncidias were shown more abundantly, in greater variety and in better condition than on previous occasions. Amongst them we noticed Lycaete Skinneri, a variety of Odontoglossum llystrix, with three fine spikes of flowers; O. luteum purpureum, a fine variety with two flower spikes; furnished respectively with fourteen and twenty-two blooms, in fine condition; O. Uro-Skinneri, and O. pulchellum, both well-flowered. Of Cattleya Trianae, there was a fine plant; also an Angraecum sesquipedale in fine condition, Cyperpediums of various sorts; Trichopilia suavis, to which an extra prize was awarded; Leslie cinnabarinaria, in unusually good condition; Dendrobium lassoglossum, with light coloured flowers; D. Devonianum, a charming species with two fine spikes; D. Wardianum, with four flower spikes; D. Farmeri, with three charming spikes; D. lituiflorum, a species in the way of D. nobilis; D. albo-sanguineum, profusely bloomed, and others, all from Mr. W. Denning, gardener to Lord Londesborough, at Grimston Park, Tadcaster. The same exhibitor also showed two plants of Dendrobium Devonianum, raised from seed ripened in this country three years ago. This fact should stimulate cultivators to experimentalize in the same direction, it being evident that there is less difficulty in raising Orchids from seed than is generally imagined. Among other collections we noticed Dendrobium fimbriatum occultatum, with beautiful yellow flowers, having a distinct dark spot on their under lip. A fine variety of Phalaenopsis Schilleriana, with very broad flowers, of fine quality, was shown by Mr. Williams, of Holloway. A purple variety of Odontoglossum Alexandrae, called roseum, received a first-class certificate, as did also an excellent kind called C. Andersonianum, the result of a cross between O. gloriosum and O. Alexandrae. The beautiful Masdevallia Harryana, a fine deep magenta-coloured kind, previously named amabilis, was shown by Messrs. Veitch. A large pan of the beautiful Anthonochilus imperialis, in flourishing condition, was exhibited by Mr. W. E. Dixon, Norwood Nurseries, Bexley. The same exhibitor received a cultural commendation for a group of rare and rare plants. A cultural commendation was also given for a handsome plant of Beaumontia grandiflora, bearing great trumpet-shaped white flowers. This was shown by Mr. J. Chambers, gardener to J. Lawrence, Esq., Eddington, Surrey. This plant is commonly considered difficult to cultivate—an idea which the specimen just adverted to tends to annihilate.

Perhaps the most attractive plant in the exhibition was a magnificent specimen of Medinilla magnifica, fully eight feet in diameter, and orna-

mented with some half hundred glorious pendent racemes of rosy pink inflorescence. This was shown by Mr. Williams. Six pots of Mignonette trained as pyramids, about two and a half feet in diameter, received a first prize; these, together with three plants of tree Mignonette, filled the house with fragrance, and formed objects of great attraction. These were shown by Messrs. Rollisson, of Tooting. A cultural commendation was awarded for a fine basket of Clematis, from Mr. Noble, of Bagshot. A cultural commendation was likewise awarded to some splendid varieties of Cyclamen persicum from Mr. Wiggins. A collection of Cyclamens was also exhibited by Mr. Goddard, gardener to H. Little, Esq., Cambridge Villa, Twickenham, to which an extra prize was awarded. Roses in pots and cut blooms were unusually fine, and largely exhibited by Messrs. Veitch, Mr. Wm. Paul, and Messrs. Lane & Sons. A very fine tea-scented variety in Messrs. Veitch's collection, named Belle Lyonnaise, received an extra prize. Prettily flowered young plants and cut flowers of Camellias were also shown, as were likewise some nicely flowered Rhododendrons and Azaleas. Of the latter we noticed the singular variety called A. linearis, which is more interesting in a botanical than in a cultural point of view. For a well grown Caladium, Prince Albert Edward, a cultural commendation was given to Mr. Dixon. A cultural commendation was also awarded to Agave geminata Williamsii from Mr. Williams; likewise to Eurycoma amboinensis, from Mr. Bull. Amongst other things were several very fine palms, such as Kentia australis and Forsteriana, Veitchia canterburyana, Calamus verticillaris, a variegated form of Rhapis fabelliformis, Uaceopermu van Houttei; and to one named Pitycopermu Alexandrae, from Messrs. Rollisson, an extra prize was awarded.

Amongst Dracaenæ we noticed D. Macleayi, a fine dark coloured variety, with broad drooping leaves, in the way of D. Cooperi. A fine pan of Trichomanes radicans from Mr. Dixon received an extra prize; from the same exhibitor also came a grand specimen of Gleichenia Speluncæ, and a large plant of Platycerium grande, growing on an old tree fern stump. We also observed Philodendron Lindenii, a noble leaved plant.

Cinerarias distinctly coloured, and otherwise in beautiful condition, were furnished by Mr. Cutbush, and some of good form and substance came from Messrs. Standish & Co. To Epimedium lilacinum, a charming little plant, an extra prize was awarded. Associated with it were double and single Primroses with white and lilac; also the lovely P. nivalis, Lily of the Valley, Polemonium reptans, Adonis vernalis, Trillium grandiflorum, Pariesia, a pretty dwarf Fritillaria, and a variegated form of F. imperialis, the exquisite little Iris pumila, Funkia, Pinks, &c., all from Mr. T. Ware. A basket of a fine tricolor Pelargonium, named Mrs. Headley, two baskets of Auriculas, and a collection of the new white forcing pink, named Lady Blanche, were exhibited by Mr. Turner, of Slough. From Mr. Cutbush came a group of Aruncus auro-maculata with large yellow blotched leaves.

Fruit was shown in good condition; a cultural commendation was awarded to a box of Lady Downe's Seedling Grapes, in fine plum condition, from Mr. J. Hudson, gardener to J. C. Inthurn, Esq., Champion Hill, Camberwell. Apples, both dessert and kitchen kinds, were contributed; of dessert sorts, the winning varieties were White Nonpareil, Claygate Pearmain, Cornish Aromatic, Cockle Pippin, Cox's Orange Pippin, Scarlet Nonpareil, Ribston Pippin, and King of the Pippins. Among kitchen varieties the following were the successful sorts, viz., Northern Greening, Mrs. Incomparable, Striped Beeching, Wellington, Alfriston, Kentish Fillbasket, Blenheim Orange, and Dumelow's Seedling. A dish of good Chaumont Pears were also shown by Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury. For three fine heads of Snow's Winter White Broccoli Mr. Ross also obtained a first prize. Three large heads of white Broccoli, called Matchless, came from Mr. Cooling, Bath. A brace of Seedling Cucumbers, called The Winter Supply, was shown by Mr. T. Record, gardener to the Marquis of Salisbury, Hatfield; as were also three dishes, one of limes, one of citrons, and the other of Sweet Lemons, from Mr. E. Elworthy, gardener to Sir W. G. Trevelyan, Bart., Nettlecombe, Somerset. An interesting collection of West Indian Yams (*Dioscorea sativa*) was exhibited by Messrs. Rollisson.

BIRMINGHAM EXHIBITION.

The local committee of the Royal Horticultural Society held a meeting on the 14th inst., the Marquis of Hartford in the chair. There was a large attendance, to whom it was announced that H.R.H. Prince Arthur had signified his intention of opening the show to be held at the Lower Grounds, Aston, in June next. It was stated that the sum of £100, placed at the disposal of the implement committee for prizes, should be appropriated to the award of medals as under:—Five gold medals, one to be given for the best horticultural building; one for the best heating apparatus; one for the best collection of vases or other garden decorations; one for the best collection of garden machinery, tools, &c.; and one for the best collection of garden wire-work. It was further recommended that the judges should be empowered to award silver and bronze medals not only to any merititious exhibits in the classes just enumerated, which might not obtain gold medals, but also to any others besides those which might appear to them to deserve such a distinction. They were of opinion that the funds at their disposal would enable them to offer five gold medals, thirty silver medals, and forty bronze medals. It was also reported that Mr. Joseph Moore had been commissioned to prepare designs for the medals.

The draft of the schedule of prizes was then submitted and agreed to, but as contributions to the special prize fund were reported to be coming

in daily (it amounts at present to £880, including £100 subscribed by the Birmingham "Rose Show"), a sub-committee was appointed with full authority to revise, amend, curtail, or extend the special prize list as circumstances may necessitate. A class is set apart for dinner-table decorations, to be exhibited and judged by gas-light. Each exhibitor will be required to completely furnish a table for fourteen persons, and the decorations must be so arranged as to show the best means of utilizing fruit and flowers in its adornment. The prizes offered are £20, £15, £10, and £7, which should secure an attractive exhibition. The local committee of the Royal Agricultural Society's show of last year have contributed a special prize of £10.

THE GARDEN IN THE HOUSE.

THE CREEPING MYRTLE (MYRSIPHYLLUM ASPARAGOIDES).

In the interesting notice of this plant in No. 15, p. 324, the writer expresses an opinion that its application for ornamental purposes must be peculiar to America, as he did not find it in European plant catalogues, nor mentioned in any foreign works on floriculture. I am glad to learn, from the editorial note appended, to the description which you have given of this interesting plant, that it is occasionally to be met with in botanical or rare collections in this country; but I wish to remark that it is well known in Sicily, and that it is cultivated and largely used for ornamental purposes in Palermo. The Palermitan belles find, from experience, that its delicate graceful sprays outlive all other green foliage in the heated air of a ball-room, and they arrange it with great taste for personal decoration, adding some of their splendid camellias, or other brilliant flowers, which grow in profusion in what is literally a land of flowers. I made an experiment some years ago at Palermo with a branch of the *Myrsiphyllum asparagooides*, which was brought to me as a specimen of the plant so much used by ladies there for the decoration of the hair, on account of its long retention of greenness and freshness. It was laid on a table in a room without water, in order to ascertain how many hours it was possible to keep it fresh. Unfortunately, no record was kept of the actual length of time, although it impressed all of us at the time. I have long wondered why our English ladies did not adopt this very beautiful and delicate plant as an addition to their ball-room toilette. I can only surmise that its merits have been comparatively unknown in England, and I trust that your interesting notice, coming, as it does, all the way from across the Atlantic, will eventually lead to its universal cultivation in greenhouses in this country.

G.

ARRANGEMENT OF VIOLET BLOOMS.

VIOLETS are not easy flowers to arrange well; their heads are too heavy for their legs. I never like to see them stuck into a vase in a bunch, just as they are sold. Often we find them in vases without any leaves or foliage of any kind. Then I am uncharitable enough to consider that those who so arrange them, if arrangement it can be called, have less taste than the children who gather them and make them up into bunches, encircled with a few of their own leaves. Where time is not an object, and fine blooms of Neapolitan Violets are at your disposal, it is worth while to pass a piece of fine soft wire (called by bouqueteurs, binding wire) through the back of the flower and to curve it over in the direction of the flower-stalk, giving it one or two turns round the stalk to keep it in its place. Flowers so treated, can be stuck one by one into a vase or saucer full of moss, and thus preserve the position in which they were when on the plant. A dozen blooms thus prepared and arranged amongst a sufficient supply of their own leaves, have a natural effect, and their appearance commends itself, even to those whose taste has not been, so to speak, educated. But many have neither the time nor the inclination for such fidgety work. To them I would recommend the use of Aconite leaves, or of any other similarly constructed leaves that are out thus early; tie two or three of them together by their stalks, which should be cut two inches long, and place the bunch into a saucer with the tips of the leaves resting upon its edge. The violets may then be placed between the divisions of the leaves, and will be supported by them in a natural position. If near the sea, small plants of *Plantago coronopus* might be used, instead of the finely divided palmate leaves of the Ranunculaceous plants to which I have referred, or other leaves from plants of the same natural order.

W. T.

COVENT GARDEN MARKET.—March 22nd.

Flowers.—These chiefly consist of Hyacinths and Tulips; Cinerarias, among which dark blues prevail; Spring Heaths (E. gracilis); Epacries; Azaleas; *Spiraea japonica*; Cyclamens; Fuchsias; Pelargoniums, of many kinds. Cut-flowers of Orchids and other things are also abundant. Bouquets consist of white Camellias or some light coloured Tea-rose as a centre piece, about which are tastefully arranged Lily of the Valley, Cyclamens, Mignonette, light-coloured Orchids, wired "pips" of white Hyacinths, Heliotropes, the jasmine-flowered Bonvardia, blue Cinerarias, and Pelargoniums, edged with Maidenhair Fern, sprays of which also pervade the whole of the bouquet. "Button holes," backed by sprigs of Ferns, consist of pink, white, and yellow Tea-roses, in front of which are placed double red Pelargoniums. In others are sprays of Spirea, a white rose-bud, and a bit of red Pelargonium, or some red-coloured Pink; others again consist wholly of a white Pink set on a green background.

Early-leaving Horse-Chestnut.—The best known tree in Paris is an early-leaving horse-chestnut in the Tuilleries Gardens—the "Marronnier du vingt Mois." It comes into leaf a few weeks earlier than the other trees in the gardens, and is popularly supposed to be in good leaf on the 20th of March every year, though we saw it behind its lime in the spring of 1867. It is not generally known that such trees are by no means rare. In Kensington Gardens on the 6th of March this year we saw half a dozen within sight at the same time, and all with partially unfolded leaves. The majority of the trees of the same kind were quite bare, and we have since observed the same thing in several of the London parks.

Pansies in Bouquets.—In passing through the central row in Covent Garden the other day I was surprised and pleased to see dark coloured Pansies tastefully worked into bouquets. The bouquets were for the most part composed of white Camellias, and other pure white flowers. The effect of the rich dark pansies among these was very charming as well as quite novel.—H. V.

ANSWERS TO CORRESPONDENTS.

Y. (Exhibitions of Hyacinths may now be seen at the nurseries of both Messrs. Veitch and Cutbush.)—J. T. T., GUERNSEY. (From any of the Paris nurseries where herbaceous plants are grown. If you get plants in pots they may be planted out at any time.)—BIRCHFIELD (Through any good nurseryman).—M. (Next week.)—MESSRS. M. (The "Cow Parsnip").—C. G. (Tobacco smoke will kill green and other fly indoors; outside try applications of tobacco water, sulphur, and Scotch snuff, washing them off on the second or third day with clean water applied with force from the garden engine or a powerful syringe.)

NOTICE.—Country booksellers having reported some of the earlier numbers of "The Garden" to be out of print, we beg to state that every page has been stereotyped, and consequently "The Garden" can never run out of print.
Readers who may find it difficult to procure THE GARDEN regularly through the newsagents, may have the numbers sent direct from the office, at 19s. 6d. per annum 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsagents, at the railway book-stalls, and from the office.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37; Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

GARDEN

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE SIX OF SPADES.

CHAPTER VIII.

INDEED, I think that there are few institutions more healthful, and few sights more pleasant to the eye and heart, than that of a village flower show. It induces first of all that communion of classes which teaches men, more forcibly than schools or sermons can, to recognize their place and duty; and does this with a cheerful ease and freedom very sparingly (please to observe the fashionable adjective "spare," a new shilling, I assure you, in the coinage of etymology) in the assemblies of Englishmen. Orchids, delicately reared in heat, are gathered under one tent with the hardy wild flowers of the field; the luscious Grape from my lord's vineyard rests upon the same table with the Gooseberry, hirsute and corpulent; and as the question is, not which of these is more beautiful or better than its neighbour, but which is best of its kind, which has been most carefully and wisely cultivated; so when men meet together, lawmakers and brickmakers, coronets and "billy-cooks," the consideration for each to take home with him is this, not whether he is richer in purse or higher in grade than another, because God has put all men in their places, but whether he is useful and good in himself. It concerns every man, and vitally, to reflect, not whether he is a duke or a ditcher, for that is pre-arranged and fixed, but whether his dukery or his dike are in the best available condition.

If it be said that very few will make this inference, or note my obscure analogy, I may lay stress at all events upon the fact that *there is* the communion of classes, pleasantly established, and that from this kindly genial intercourse new sympathies cannot fail to spring. All are in good spirits and good temper to begin with. The Duke congratulates Mr. Oldacre upon that glorious basket of forced fruits, Grapes, Peaches, Nectarines, Apricots, worth a hundred guineas in Covent Garden Market; and Mrs. Cooper is still more delighted with a long-legged dusty Geranium, which would soon put an end to the Pelargoniums at Slough, by causing them to die with laughter, but which, nevertheless, has achieved to-day the third prize for window plants.

There comes a friendly fusion of exhibitors. The owner of the soil has hearty words for that occupier who proves to-day that he is not abusing it, and whose neat garden proclaims to the landlord, every time he passes in his carriage, industry, happiness, and the rent gradually accumulating in the recesses of an old stocking. Again, I say, it is a goodly sight. The people of a village ought to be as one family, and to-day they seem to be so; and when the band of our Volunteer Riflemen—a good band, too, though the performer on the trombone might be accounted podgy for military purposes—concludes with "God Save the Queen," we feel every one of us that we have met for good, that there are refreshments in life which can cheer and strengthen for many a toilsome day, and that the surcest, purest happiness is that of men working with the means which are at hand, so ample and so apt when charity seeks them, to make those around them happy. I remember to have heard from an elderly colonel of my acquaintance, that, when a young man, he was in the habit of going frequently for tea and piquet with an invalid aunt, because he thought it his duty. It was an awful bore at first, he said, but he afterwards found in his kinswoman a most genial companion and excellent friend. "I learned more wisdom from that gentle sufferer," he told me, with an earnest thankfulness, "than could be

extracted from a platform-load of Surgeons; and, though I give you my honour that I always thought, until the day of her death, that she was in straitened circumstances, she left me ten thousand pounds." "Oh!" exclaims the sceptic, with his unbelieving sneer; and I only wish the colonel could hear him. He would repeat his small observation in a very different key.

But where's the Curate? We left him communing with Cooper *pere*—he is now with Cooper *filis*. And there can be no question whatever that Tom junior is at this moment the happiest individual out. He has won the first prize for a posy of wild flowers (we call it a bouquet in our schedule, but I like the sweet old English word far better, and so do the little florists), achieving this victory over thirteen competitors, and surmounting obstacles of a stupendous magnitude; for it is currently reported, not only that Billy Jenkinson's mother had been seen, on her return from weeding, with large contributions of field flowers for her sweet William, but further that Tim Norris's big brother "got all his, and tied 'em up for him." Against these fearful odds, these grand advantages, Tom Cooper has won the day; he has utterly discomfited the mother of Jenkinson and annihilated the large fraternity of Norris. There he stands, reading the card, which proclaims his conquest, for the ninety-third time, and merrier than Mr. Merry himself when Thormanby shot forward opposite the stand, and all that he wished was won.

Whence came, I wonder, Tom's taste for wild flowers, and his cleverness in grouping them so prettily? Ask him, and he will look up with a smile at the Curate, who is even now suggesting to him how he might have made some little improvements; and if you would know furthermore how and when the lesson is learned, ask the Curate, as I have asked, and you will hear his system.

On Sunday evenings, in the summer-time, some twenty boys from the village school assemble, when the weather is fine, at his Reverence's garden gate. They have been good lads in church and school, or they would not be there; and as our ecclesiastical Spade comes out, with some books on wild flowers in his hand, little blue-eyed Joe Birley plucks him by the coat, and whispers proudly into an ear very promptly inclined to receive the information, "If you please, sir, I said all that big cholic" (collect for the day intended) "to Miss Rose, and never made no mistak." Whereupon Joseph is permitted to carry one of the volumes for reference, a dignity esteemed in that boy brigade as highly as the Victoria Cross by a soldier; and off they go for the fields. At the first stile, which leads to the inclosures, there is a halts for choosing sides, the Curate nominating two of the most experienced artists as leaders, and these electing their forces alternately. Then the subordinates receive from their commanding officer their special orders and instructions; some are to remain with him in held in arranging; these are to gather white flowers, those pink, and so on; while others must bring "totter-grass," fern, or variegated leaf, to complete the outer circle of the collection.

Each company has a librarian, whose office it is to find in his illustrated works the flowers brought in by his brothers, and to communicate their name and history. Their English names, mind you, for our Curate wisely declines to muddle their small brains, and weary their young jaws, with botany. I never saw him angry but once, and then with a bilious old gentleman, who proposed that all wild flowers exhibited at our show should have their Latin names and classification. "I'll tell you *my* mind," quoth the curate, "botany is a grand science for those who have the head and the time for it, but it's about as useful to a ploughman's child as a ball-room fan to an Arctic voyager; and, therefore, so far from rewarding any of my young rustics for Latinizing our dear old country flowers, I should be inclined to award for the precocious pedant transportation to Botany Bay. Carry out your idea, and we shall have the labourer's child no more exclaiming, 'Oh, faythur, there's a Dandelion!' but 'Aspic, O paterfamilias dilecte, ubi Leontodon Taraxacum flavescit!'" while his sister, pointing to a Buttercup, shall astonish its mammy by requesting her to "employ her optical apparatus in the direction digitally indicated, and to admire the Ranunculus bulbosus, of the class Polyandria, and the order Polygynia."

"I try to teach them something better about Buttercups,"

he said to me, as I met him one evening with his boys, and he referred to the subject; and plucking one of the flowers in question, he held it before a charming little fellow, who could scarcely have seen half-a-dozen summers, and asked him if he had learned any verses about it. The answer came promptly, in that soft reverential tone which makes a child's recitation so very touching:—

"It would be wrong on pomp or dress
To spend our thoughts or hours;
Another lesson Christ has taught,
Showing the simple flowers."

"There's not a yellow Buttercup,
Returning with the spring,
But it can boast a golden crown
As bright as any king!"*

"That will do," said the Curate. "Now, Johnny," and he called another of his pupils, "Tell this gentleman about 'all things bright and beautiful!'" And Johnny began forthwith:—

"All things bright and beautiful,
All creatures great and small,
All things wise and wonderful,
The Lord God made them all."

"Each little flower that opens,
Each little bird that sings,
He made their glowing colours,
He made their tiny wings,

The rich man in his castle,
The poor man at his gate,
He made them, high or lowly,
And ordered their estate."†

And Johnny was commanded to cease firing. "They love these verses," our pastor continued, "as they love the flowers; and my hope is, that through life they may count the one with the other."

"There is a wondrous revelation in these earth-stars, blue and golden, as Longfellow has told us in his grand melodious rhymes, and I trust we are reading it together. I love to imagine that when these boys are men, the labourer, going to his work and from it, may be reminded, as he looks upon these old familiar friends, of the lessons we are learning now; that 'the hewers of wood' may stop to recognize, with pleasant memories of the past and brighter hopes of the future, the Anemone, the Primrose, the Violet, the Lily, or the Hyacinth; that pale mechanics, in their Sunday walk, may repeat to their little ones the precepts which are taught by the flowers; and that soldiers and sailors far away may dream of the meadow and the grove, and awake with a deeper affection for their beautiful English birthland, a braver heart to maintain its freedom. Yes, I love to imagine that the recollection of these happy wanderings among the summer flowers may help to revive in weary men the freshness of boyhood's happiness; that some of these lads may hereafter be of that company of whom our greatest sacred poet has said:—

"There are, in this loud stunning tide
Of human care and crime,
With whom the melodies abide
Of th' everlasting chime;
Who care not for their heart,
Through dusky lamp and strangling mart,
Plying their daily task with busier feet,
Because their secret souls a holy strain repeat;"

and may know, to quote the words of our greatest divine since the Reformation,‡ how to 'reconcile Martha's employment with Mary's devotion; in the midst of the works of his trade to retire from time to time within the chapel of his heart; and to converse with God by frequent addresses and returns.

"I want these little men to be what Mr. Kingsley calls 'minute philosophers,' to find by the roadside and by the brookside some of 'the riches which God has given the poor,' to feel, as it is wisely said by Alphonse Karr, in his delightful 'Tour round my Garden,' 'Le bonheur n'est pas une rose bleue,

* From "Hymns for Little Children."

† Keble.

‡ Bishop Jeremy Taylor.

le bonheur est l'herbe des pelouses, le liseron des champs, le roses des haies, un rato, un chant, n'importe quoi.'"

And much more pleasant converse had I with our Curate on that sweet summer's eve, what time the happy boys were racing to and fro with the pretty posies in their hands; and the gorgeous kingfisher shot down the brooklet, like a meteor, at the sound of their merry voices; and the swift trout darted to his hole, as they plucked the campions from the bank; and the landlark cracked in the mowing grass, complaining, I infer from his harsh tones, that, being long-toed and formed for the swamps, as a great naturalist tells us (Darwin "On Species," page 186), he should be thus uncomfortably located in the meadows; and far in the distance "the cuckoo told his name to all the hills," some of them distinctly repeating it, as though Mr. Cuckoo were going upstairs to a party; and we wandered and wondered, until the dews wept for that gentle day; and the two floral armies fought the battle of the bouquets, and victory was adjudged; and victors and vanquished supped, "as only boyhood can," upon the Curate's bread and cheese and beer; and we all went thankfully home, and "bedward ruminating."

(To be continued.)

HORTICULTURAL TOASTS IN AMERICA.

CHARLES DICKENS, in one of his letters from America to his friend Forster, wrote:—"The general talent for public speaking here is one of the most striking of the things that force themselves upon an Englishman's notice. As every man looks forward to being a member of Congress, he prepares himself for it, and the result is quite surprising. The old custom of drinking sentiments is quite extinct with us; but here everybody is expected to be prepared with an epigram as a matter of course."

A rather remarkable display of the kind of epigrammatical toast-giving alluded to by Dickens took place at the anniversary dinner of the Massachusetts Horticultural Society some few years ago, from which, suppressing the names of the epigrammatists, a few examples may be given, which will not be altogether out of place in the pages of THE GARDEN.

1st TOAST.—HORTICULTURE—that rational and noble art which regales and delights all the senses; which nourishes a generous gratitude to the Author of all Blessings, and enables man to create a new Eden in place of that which his first ancestor forfeited.

2nd TOAST.—THE MEN OF SKILL in enlightened cultivation, who have changed the Crab into the Newtown Pippin, and the Hog-peach into the Noblesse and Vanguard.

3rd TOAST.—THE ART which makes all climates one, making the tropics tributary to hyperborean regions, and giving even to snowy Russia the Pine-Apple and the Mangosteen.

4th TOAST.—THE ENCOURAGEMENT OF A TASTE FOR FLOWERS.—God gave them for our delight, and it should be one of the signs of a cultivated age to love and study them.

5th TOAST.—AGRICULTURE AND HORTICULTURE.—The allied powers that make the Desert teem with abundance, and bid the Wilderness exhale the perfume of Roses.

6th TOAST.—THE TWO GREAT FACTS.—God made the first GARDEN; Cain built the first city.

7th TOAST.—THE RISING GENERATION.—May these young TWIGS be so TRAINED as to need but little TRIMMING; may they become valuable STANDARDS, produce FRUITS worthy of a PREMIUM, and receive prizes at the great FINAL EXHIBITION.

8th TOAST.—GARDENING.—The art by which Nature is made to improve her own productions.

9th TOAST.—May we henceforward deem it more honourable to crown with garlands the successful cultivator than to gather laurels on fields of battle.

10th TOAST.—THE GREATEST HAPPINESS OF THE GREATEST NUMBER. The whole world a GARDEN: hands enough to cultivate it, and mouths enough to consume and enjoy its abundant produce.

It is needless to add that each of the foregoing toasts was received with upcries and long-continued applause, or that many other toasts were spoken and drank to on that "festive occasion," some of which may possibly be reproduced in these pages at some future opportunity.

THE LIBRARY.

NATURE; OR, THE POETRY OF EARTH AND SEA.*

ILLUSTRATIONS that make hideous the subjects which they attempt to "illustrate" are unfortunately not uncommon. But in the book before us there are illustrations in which the very life and spirit of vegetation are expressed so truthfully that

one obtains a new idea of the exquisite power of good engraving as a teacher. The things represented seem to live—to toss on the breeze, to bathe in the glorious sun; yet all is in black and white. By such art as this we teach in the highest sense. Numbers have no opportunity of seeing at their best many of the subjects with which they have to deal. This particularly applies to gardeners, who are debarred from seeing many of the noblest objects of their charge in their native habitats or in the places where they happen to attain perfect beauty and vigour in this country. To such, illustrations which fully render the beauty and the dignity of the subjects they represent are a priceless boon.

The present volume, and some other books recently published by Messrs. Nelson, seem to inaugurate a new era in the art of faithful and artistic rendering of the most beautiful objects in nature. The illustrations are mostly drawn by Giacomelli, who seems the prince of graceful designers on wood. To give some idea of Madame Michelet's style, as well as of the charming illustrations with which the book abounds, we quote a portion of her introductory chapter on the garden, accompanying it by one or two of the beautiful engravings:—

Waterside Vegetation.

"The garden! How many meanings in that one single word! How many interpretations have been given to it! But remember that the garden which our hearts really love is no vast space in which the vision is utterly lost, but rather that limited enclosure which retains the soul half captive; its concentration acts all the more powerfully as an inspiration, and lends wings to our dreams. A limited enclosure, and even something less. Who does not

* "Nature; or, The Poetry of Earth and Sea." From the French of Madame Michelet. With 200 Designs by Giacomelli. London: T. Nelson & Sons.

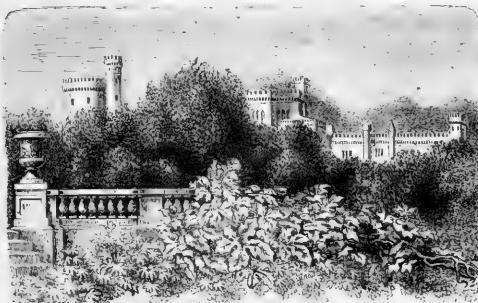

remember the pathetic history of the prisoner of Fenestrelle, all whose garden was a tiny lowly herb, which had sprung up between two stones in the lonely courtyard? And this herb took entire possession of him, linked him to heaven and space, and so firmly held his soul that even liberty would have been nothing to him without it. What more could he need? He who has loved most truly, he it is who alone has thoroughly comprehended the *povera Picciola*.

"Fortune does not allow all of us to see the globe—the wide, wide world. But all of us may wander in this garden—the miniature of a world, which furnishes us with a little turf, a limited degree of cultivation, something of the shade of woods and the freshness of waters—sometimes the sweet illusion of a fair perspective—and the vague uncertain murmur as of distant seas and dying waves.

"I do not speak here of those monumental gardens which are the pride of great cities; or, rather, their saloons, given up to noisy and thoughtless crowds. Much more heartily do I love that little plot of ground of which Virgil speaks; the quiet retreat of the good old man to whom War had left but a small portion of his demesne, and that not the best. Yet not the less did it contain everything—the agreeable and the useful—grass, vegetables, fruits, and even bees, with a few tall and venerable trees, rich in so many pleasures for him who sat beneath their shade.

"Those great and noble trees, in the potent magic of sunshine and shadow, possess all the charms of memory. How many souls, (as we feel) akin to our own, have passed away, never to return again! In spite of ourselves we dream of them: all life seems informed with regret.

English Palace and Gardens.

"But sweet friendships are more easily formed with secondary and less imposing lives—with lives, that is, within our own range of sympathy. The fruit tree which mounts no higher than ourselves, and droops its fruit into our grasp—and, still lower, the humble flowers of the field—these are our true friends. And the latter—so small and so exquisite!—seem to breathe forth in their fragrance the subtle soul of the earth; one might almost say, its thoughts.

"The famous 'Paradies' of Persia were no more than this—an agreeable confusion of fruit and flower. Even the kings in their

royal gardens were desirous of nothing more. Not an inch of ground was wasted on an empty effect of grandeur. No trees everywhere displayed their barren majesty. There were few broad alleys, but, on the contrary, a maze of narrow paths wound here and there among the orchard-growth. Flowers—everywhere flowers! In that land of light they seem a coronation, and it is with them that nowadays we have awakened a glow of warmth in our pale West. In the few openings of our mighty forests, what have we? The French vervein, whose sombre leafage is scantily brightened by a single and almost imperceptible flower.

"From Persia we have derived all the adornment and wealth of spring. It seems as if its sunshine were not so much warm and genial, as fresh and youthful; it is, so to speak, a ray of dawn. Tulips, anemones, jonquils, and all the variety of ranunculus, wore its gifts; eyc, and those violets, lilies of the valley, pinks, and narcissi which seem so thoroughly our own. The delicate lilac, the peach with its shower of virgin snow, and finally, supreme above all, the rose in its close sympathy with the bulbul—song mingled with sweet odours. All this, too, for the first innocent hour of the young year! Later on, with the languishments of summer, the daughters of India come to greet us, and the children of Tropical America."

"Nature" is divided into seven "Books," as follows:—I. The Garden; II. Pastoral Scenery; III. Woodland Scenery; IV. Mountain Scenery; V. River Scenery; VI. Lake Scenery; VII. The Sea; each of these being again divided into three to twelve chapters. Our extracts and illustrations speak sufficiently of the merits of the book, though they tell nothing of its excellent finish in printing and paper. We strongly recommend it to every lover of nature.

THE FRUIT GARDEN.

CHOICE APPLES ON WIRE FENCING.

MANY years ago, on taking charge of the gardens here, I found the slip of ground outside the kitchen garden protected with a rabbit-proof fence. The fence consisted of a dwarf wall and wire netting in these proportions: on the wood side the wall was a little more than two feet high, on the garden from eight inches to one foot; on the top of this wall wire netting two feet high was fixed to a strained wire at top and another at bottom. Thus the fence was four feet high from the outside, and a little less than three from the inside. The height so made up has proved sufficient for the exclusion not only of rabbits, but also of hares. Its bare and naked appearance was, however, anything but pleasing. Therefore for that reason, as well as on economic grounds, it was resolved to cover it with fruit trees. The east side was consequently at once devoted to pears, the north to apples, and the west partly to apples and partly to plums. I will, however, now only allude to the apples, which have done best, although the pears have done well. The plums have not succeeded satisfactorily—the cold spring winds, against which the net affords no protection, generally blighting the blossoms, in spite of other protecting expedients. For this reason I would not recommend plums for such positions. But such a fence has proved itself one of the very best places for apples and many of the harder varieties of pears.

Having planted the young trees at about eighteen feet apart, the next process is the training. If the tree is intended for horizontal training, little cutting will be needed. The main shoot might be bent and twisted in various forms, to compel the dormant buds to break throughout its entire length. A simple removal of the terminal buds, and the proper amount of divergence from the straight line, will generally suffice. The space at command may thus be furnished in less time. There is attending this mode just the risk of breaking the buds; occasionally some one or more of them refuse to yield to such compulsory practice, and then the form of the tree is marred for life. For this reason, and for very dwarf trees, it is safer and surer practice to cut them boldly back, say, two or three months after planting, to within six inches or a foot of the stock. From the very bottom of the tree four or six shoots will then spring forth. The lower ones on each side must then be carried to the right and left horizontally, and the others ranged above them in regular order, and at regular distances. The width of the branches from each other is an

important point. The object being a screen, the branches should be closer than usual. On a space not quite three feet high six or seven branches are arranged; thus close, of course the screen is complete; but perhaps for general purposes, one foot between the branches would be a safe rule. Having started the trees on the right track, the next consideration is, when are they to be stopped in their growing career? This brings me to the question of summer pruning, about which there are two important points. The first is the best time, and the second the proper extent to prune. In reference to young trees of this kind, don't prune them at all the first summer. Having relieved them from the knife in spring, let them not afterwards be meddled with until the autumn. Started on the right track, the further they run, within reasonable limits, the better for their future vigour. A yard or four feet will not be an excessive distance to have traversed. Towards the middle or end of September, however, it will be necessary to examine into the character of the growth made, and to bend it into the direction of fruitfulness. This will be best accomplished by lopping off probably one-third from its length, and if so much labour can be bestowed, by bending the shoot left as much back upon itself as it will endure without breaking. The tendency of this will be to equally develop all the buds on the shoot, to prevent the terminal ones breaking into new growth, and to store up in them all alike the germs of fertility. All these highly essential objects will be more effectively promoted if, towards the beginning or middle of October, the roots of the tree are carefully examined, and a few of the largest pruned. If any are found, notwithstanding the horizontal spread at planting, to have acquired a vertical bend, they must be boldly removed. This first examination of the roots must be performed with skill. Growth must be tenderly checked. If these operations are properly performed at the right period, no more wood will be made the first season, but many more of the thin angular wood buds will be developed into plump roundish fruit buds; and from this period in the history of the tree the production of such buds is to be the chief object aimed at in all future prunings of either root or top. With such a mode of planting as is here described, wood will be produced in abundance. The knife may occasionally be useful to give it the proper form, but the chief use of pruning henceforth will be as an aid to fertility. And it must ever be borne in mind that fertility is chiefly secured through pruning the root rather than the top of the tree. Root pruning may have for a time to be repeated annually, or biennially. If the trees show a tendency to run too much to wood, pruning is the remedy. After a time, however, the necessity for this will cease.

If these preliminary prunings have answered their proper purpose, the shoots next summer will be covered with fruit buds. From or near the clusters of fruit, a wood bud will also spring forth into a shoot. What is to be done with this side shoot? Let it grow until June, and then shorten it back within four or six leaves of its base. It will soon break out into new growth, and this growth may either be persistently pinched off—say every three weeks—or allowed to grow freely. I prefer this mode until the end of September, and then to cut clean off, back to and beyond the point cut to in June. The exact point must be regulated by the condition of the buds at the base of this shoot. These are our reserve for fruiting next year. Sometimes, if they are very plump, cutting close to them, even at so late a period, will start them into growth. If this happens, next year's crop is ruined; so, if fully developed, it is safer to leave a few buds of the second growth than to cut up to or beyond it. On the other hand, if the base buds are backward, cut back fearlessly to one or two buds only. This will concentrate the remaining energies of the tree upon the organization of fruit buds. However, unless well versed in a knowledge of the two kinds of buds, and the growing habits and peculiarities of different trees, it will be safer practice merely to cut back to the point shortened to in June than to go beyond it. This final shortening completes the summer pruning.

The extending growths on each shoot should be treated the same as last year, until the whole space devoted to the tree is covered; after that all growths should be stopped, pinched, or pruned, in the manner described, for the side shoots. There

will be no want of shoots for furnishing the top of the tree. If a straight stem is chosen, its leading shoot must be cut in year by year, as recommended for the maiden tree, until enough branches are formed for the furnishing of the sides. Its furnishing mission is now ended. In fact, the difficulty with liberal culture is not the want, but a redundancy, of wood, and the needful skill to turn this wood to fruitful account. By the modern improvements in fruit culture, winter pruning is reduced to a minimum. It consists in merely completing the much more important process of summer pruning. Its amount is regulated by the extent to which the shortening process was carried during the growing period. The spurs should then, if any have been left to shorten, be cut back to within a bud or two of their base. After the trees are fairly established such a shortening often becomes unnecessary. Nevertheless, the proper time of this final pruning is of the utmost consequence. From what has been said about summer pruning, it will be obvious that the trees which need most cutting now are those that were then in the most excitable state. For this reason the spurs were left longer upon them. Now this fact affords the proper cue to their final pruning. The great danger to be most sedulously guarded against is the early flowering of fruit trees. Spring frosts are the greatest destroyers of fruitful prospects. Consequently our interest is to keep the buds dormant as long as possible. With this object in view, the final pruning must be deferred to the latest moment. Therefore, instead of performing the winter pruning at the fall of the leaf, leave it until the middle or end of March; for the last cut of the knife is the startling summons for the bud to come forth and bloom.

When the trees are thoroughly established, and a fruitful habit induced, less pruning of any kind is needed afterwards. It thus happens that the induction of fruitfulness speedily supersedes the necessity of much, or any pruning; for, like any other good habit, once established, fruitfulness repeats itself readily; and this habit is the most powerful agent that can be employed either by nature or art for reproducing fertility in continuity. Vegetable life indeed seems to have no choice in this matter; and herein consists a danger to inexperienced growers. A fruitful state of a tree demands modifications of previous practice; an excess of fruitfulness may become a real danger. It is easy of course to remove part of the crop; and this ought at all times to be attended to. In the thinning of fruit it should be remembered that one fine fruit is of more value than six small ones; but I do not chiefly refer to thinning: the whole culture that induced the fruitfulness will require modification. The restrictions upon the growth of wood must be relaxed. Root pruning will not only become unnecessary, but injurious. Prunings and toppings in June may be completely dispensed with; in fact, Nature will often take this matter into her own hands by offering no growth to stop. Any young shoots that are produced may be cut close back in September without the slightest danger of the dormant buds at their base bursting into growth; but for the evil of an early bloom such is the best course to pursue, as the whole power of life should now be carefully husbanded for the manufacture of fruit. In such cases there is literally no winter pruning; the sole pruning being confined to the removal of any young growths in September.

Trees thus bent upon fruitfulness require feeding. Two or three good soakings of sewage in the course of the summer, or top dressing three inches or four inches thick of well rotted manure in the winter, will keep them up to their work for years. The fence here described has now got into this state. The whole care it needs is summer pruning and winter nourishing. A determined fruit-bearing habit has been secured, and the duty of the cultivator consists in promptly and discriminately thinning, carefully feeding, and complacently gathering the regularly displayed and tempting produce. That produce is extraordinary in quantity and fine in quality. The trees stretch right and left along the fence to a distance each way of nine feet, and the branches are arranged one above another six or seven rows deep. Their ropes of fruit are so massive in themselves, and are placed so close together, as to form a complete screen that renders the fence invisible. It is literally a fruit screen, set off to the highest advantage by the fine

foliage that struggles through, between, or out from among the continuous clusters of fruit.

Singular enough, too, although rabbits occasionally get upon the edging of the dwarf wall, and hares can reach to the lower branches by standing on their hind legs, they seldom attack the produce. They seem to dislike nibbling at the apples through the wire netting of $1\frac{1}{2}$ inch mesh. All who have seen this fence are charmed with these dwarf fruit trees, and it would be difficult to find a more profitable boundary to a kitchen garden. It combines in a high degree the merits of utility and beauty, and is just as efficient as an unclothed fence for the exclusion of vermin.

F.

PEARS IN THE CHANNEL ISLANDS.

In reply to Mr. Willis (p. 381), allow me to say that the evidence as to quality of British v. French or Channel Island pears does not rest upon the two varieties he names, viz., Chamontel and Duchesse d'Angoulême. What he says respecting these two sorts is simply in accordance with what is well known to all who have given attention to the subject of pear growing—viz., that the large, coarser varieties of pears are of better quality grown in France and the Channel Islands than we can produce them in England; and the further north the worse they are. Two hundred and fifty miles north from this place, Chamontel is very inferior, and the Duchesse is no better than a turnip. But this is no evidence as to the point at issue. I maintain that, for all qualities, size excepted, I have grown, and seen others grow, the best varieties of pears, such as Mario Louise, Louise Bonne, Seckle, and Winter Nelis, and other good sorts, of better quality than ever I have seen grown in France or the Channel Islands.

T. BAINES, *Southgate*.

COLD MASTIC FOR GRAFTING PURPOSES.

The inconveniences that always attend the use of warm compositions, and the trouble of making them, have brought very much into fashion cold mastics, which soften under the heat of the hands, or remain unctuous from the nature of their composition. Up to the present time, no cold mastic can compete with that of M. Lhomme-Lefort, manufactured by his son at Belleville, Paris. This mastic is sold in tin boxes, in which it preserves its pliability, even after the box is opened. It is spread on the graft with a spatula, and should it be necessary to touch it with the fingers, these should first be wetted. Once exposed to the air, it hardens a little. It does not crack with frost nor run in hot weather, and is the best composition that can be used. We have seen in Germany a cold composition invented by M. Lucas, pomologist. This is made of Burgundy pitch melted over a slow fire. Into this is poured the third of its weight of alcohol of 90°, stirring the mixture constantly with a stick. The only drawback with cold mastics is that they do not harden sufficiently in winter when they are applied in autumn, then the frost, having an advantage over a soft substance, can reach the tissues of the tree thus insufficiently protected.

C. BALLET.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Moss on Fruit Trees.—How am I to get rid of moss on my apple trees?—J. B., *Hertford*.—[Many scrape it off, but neither scraping, washing, nor painting have any permanent value. The ground in the neighbourhood of the trees must be thoroughly drained and enriched so as to induce a more healthy growth. The existence of moss and lichen on fruit trees is simply an indication of decrepitude, removable in the case of young trees, whose growth may be improved under more liberal treatment; but generally irremovable in old ones, on which, however, the moss does little harm beyond, perhaps, that of harbouring insects.]

Neglected Orchards.—I have lately come into possession of an orchard which has been so neglected as to be literally a thicket of weeds and rubbish. How ought I to proceed to improve it?—B.—[In the first place, burn the surface, then spread the ashes over the ground and dig them in along with a good dressing of manure. The burning is effected as follows:—A heap of faggots, prunings, and other garden refuse is piled up together, so as to form a cone; this is covered, to the thickness of some eighteen inches, with the surrounding soil, which is charred and burned by setting fire to the wood in the middle of it. One ton of wood, it is said, will burn three tons of soil; therefore by erecting and firing several mounds simultaneously in the way just described a large amount

of burnt earth may soon be obtained, and if saturated with liquid manure it becomes an excellent fertiliser. Paring and burning is also a good plan for getting rid of slugs and other vermin.]

Vines Shedding their Fruit.—The starting of my vine this year has reminded me that last season, although it started well, and was well furnished with incipient bunches, the bunches themselves, after a short time, turned yellow, and fell off. Can you tell me what was the cause of the bunches thus falling off? I should, if possible, like to take means to prevent a recurrence of it this year.—SUBSCRIBER.—[It is difficult to state the cause of your vine failure without some acquaintance with the condition of the border in which it grows, and likewise the temperature at which the house was kept during the time it showed its bunches. When forcing commences at this time of the year, if the border is properly drained, and the temperature kept at about from 60° to 65° at night, ranging by sun heat to between 75° and 80°, there ought to be no failure such as you complain of. Last year, in March, April, and May, the season was wet, and if your border, if outside, was not well drained, and if a too high temperature was kept up during the time your vine showed fruit, it would most likely fail in the way you describe. If you are in doubts about the state of the border and your vine roots, some wooden shutters, or a piece of tarpaulin, might be used to cover the border till dry summer weather sets in, and be sure not to keep the temperature too high, unless your vine is of the Muscat or the Frontignac section.—T.]

Select Pears.—Will you kindly favour me with the names of a few good Pears, such as will succeed both on walls and in open quarters?—CHATTERIS.—[The following may perhaps answer your purpose. Those marked with an asterisk do best on a wall:—Citron des Carmes, Baronne de Mello, Beurré Diel, *Beurré Rance, Beurré Hardy, *Beurré Sterckmans, Beurré d'Amansil, Beurré Superfin, *Bergamotte d'Esperen, *Duchesse d'Angoulême, *Easter Beurré, Flemish Beauty, *Glon Morçau, Jargonne, Josephine de Malines, Knight's Monarch, Louise Bonne of Jersey, *Marie Louise, Thompson's, Urbaniste, Williams' Bon Chrétien, and *Winter Nelis.

GARDEN IN THE HOUSE.

LILACS FOR INDOOR DECORATION.

LILACS stand cutting admirably; a branch is a bouquet in itself, and several branches are furnishing fit for any vase, glass, or basket. The Persian lilacs, of which there are three or more varieties—the Persica, *P. alba*, and *laciunita*, or cut-leaved—are the neatest in flower and foliage. Next in order of value for cutting are the two white varieties of the common lilac, a large and smaller one, of spotless purity, which is more than can be affirmed of the so-called white Persian variety. This common lilac is perhaps the least useful for cutting. Of a bluish tinge, it is less effective than many of the other and newer sorts. Charles X., *Coccinea rubra*, *insignis*, *grandiflora*, and *spectabilis* are among the best varieties for colour and size of bloom. These or any other high-coloured and fine sorts produce a fine effect mixed with the white and plentifully relieved with fine foliage. The latter is no figure of speech, as the leaves of the lilacs differ almost as much as the flowers, and range from purplish tints to a faded-looking green. For bouquet work no leaves of lilac are admirable but those of the Persian varieties, and of those the cut-leaved is the most effective, either interspersed with other flowers or as an outer fringe. Lilac flowers are largely employed, chiefly out of season, in bouquet making. When seen in every town square and cottage garden, and snipped in every breeze, they are very generally discarded as too common for these purposes. But the mode of making up into hand bouquets is at all seasons alike, and may be briefly adverted to.

The flowers of lilac, unless it be on weak plants of the Persian varieties, are far too large for bouquet work. Each branchlet of the bunch of blooms must be separated and mounted on an independent stem formed of small stick or wire. These artificial sprigs should be alike in size and form as near as may be. Two general styles will be needed, according to the place they are intended to occupy. Stiff compact little branches—that is, comparatively, always retaining more or less of the natural shape—should be made up for the central portions, and thinner, more slender sprays for the outer edges of bouquets. The lilac is almost equally adapted for any part of bouquet making. They form a good foundation to be dotted over-head with other more showy or contrasting flowers, such as white Camellias, Azaleas, and Eucharis. On a red ground of lilac, throwing up a few dividing sprays between white flowers have a grand effect. They mix well with most other material, and hardly ever seem out of place; and few flowers, except those of Spiraea, can exceed lilacs for fringings and finishings. Elegant drooping sprays of white lilac, partially hidden on a green ground of maidenhair fern, the double fringe contrasting with a bouquet containing three or five high-

coloured Camellias, is a bouquet as near perfection as may be in a certain style of arrangement.

Scarcely anything need be added about the culture of the lilac. The plants grow anywhere and anyhow. In the dark sunless courts of great cities, half choked with dust and wholly begrimed with soot, the lilac lives and opens its fresh treasury of sweets every May. Its home is the shrubbery or thin wood, though in the commonest gardens, on waste places, hedgerows, the lilac, is found. Still the plant pays for culture. Give it good soil and a clean rich root run, enriched with well rotted manure, and the leaves and flowers will well repay the trouble. They will reach a size, acquire a substance, put on a glow of colour, and diffuse a fragrance far beyond the reach of commonplace lilac, if indeed any lilac can be properly called common. Lilacs have a tendency to overcrowd themselves into weakness from below, and over-flower themselves into weakness from above. For remedy the first, thin out or remove all the suckers; for the second, behead the plant and start afresh. It is well to keep up the stock by planting a few suckers a yard or so apart every year. To cut the largest amount of bloom from the smallest area of leaf or branch, lilacs ought to be kept to a single stem like huge standard roses. Allow no suckers from root or stem; prune back any irregular branches that may break away from the head. Trained and managed thus, the plants become highly artistic, and will yield many more and fair better flowers for cutting.

D. BURY.

HANGING BASKETS AS HOUSEHOLD ORNAMENTS.

In our large cities, one of the most fashionable diversions of the ladies is to fill their windows with pretty plants, either planted in *jardinières* of costly tile, or else in hanging baskets of most rustic make. After a little time, when they have grown to appropriate height, and the dooping plants have attained sufficient length, the beauty of the window garden is apparent.

Fig. 1. Suspended Window Basket.

Every visitor on the very moment of entrance into the room is pleased at the simple beauty of the flowers and plants, and even the passer-by on the side walk will stop for a moment in his hurry, and look upon the cozy bower of bloom just inside the glazed window panes.

Fig. 1 is a design for a hanging basket. The box is made of handsomely carved wood, the inside lined with zinc or clay;

the basin is filled with earth, and in it are planted Begonias, Caladiums, Coleus, Geraniums, Ivy, Callas, and quite a variety of other flowers. The size is about 2 by 3½ to 3½ feet. Few or no hanging baskets we have ever seen surpassed this. Fig. 2 is an illustration of a large, deep basket filled with a dense growth of

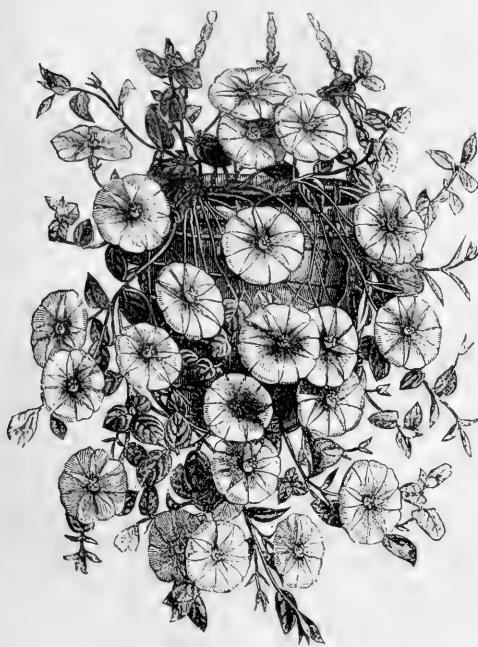

Fig. 2. Blue Convolvulus.

the *Convolvulus manananicus*. This is a highly ornamental plant of drooping, half shrubby character, slender habit, with a profusion of elegant light blue blossoms, upwards of an inch in width, forming an admirable plant for suspended vases or baskets. It continues long in blossom, and thrives very well in a room.—*Horticulturist*.

GARDEN DESTROYERS.

THE LACKEY MOTH.

BY EDWARD NEWMAN.

THIS lackey is only too familiar to all who possess gardens or orchards. In insect biography we always begin with the egg, and this, the first stage of its existence, is in the present instance the most interesting stage, because the most abnormal. We are accustomed to see some insects' eggs shaped like ninepins, and set up on end as if for a game at skittles, and we constantly find others shaped like a Dutch cheese, and glued fast by the base to the upper surface of a leaf; but it is not common to find a hundred or more of the eggs of any insect arranged with symmetry in a circle, round a twig, and united together so as to form a compact broad band like a bracelet or armlet; and this is exactly the manner in which the female lackey deposits her eggs. When you have cut the twig in order to preserve this curiosity, which must attract the notice of even the most incurious, and the twig has shrunk in drying, the bracelet can be moved up and down, round and round, with the same facility as a real bracelet on the wrist of its wearer. Each individual egg is fashioned something like that production which for some occult reason is called a pork pie, a delicacy supposed to be particularly attractive to the frequenters of the Crystal Palace and of

railway "refreshment rooms"; there is a slight depression on the top, and round this a raised rim. Such is each egg *per se*.

It appears that the parent female is possessed of two pear-shaped reservoirs, situated in the lower part of the abdomen, and filled with liquid glue, or at any rate with something that has the appearance and properties of liquid glue. Each of these reservoirs or glands has a passage connected with the oviduct, and at the moment of the passage of the egg through the oviduct a portion of this glue is discharged, and completely envelopes the egg, not only fixing it to the twig, but forming a coating or shell exterior to the ordinary egg-shell. The glue of which this top coat is formed instantly becomes hard by exposure to the atmosphere, and is so tenacious that two pieces of cardboard once cemented together with it cannot be separated without tearing. The glue is perfectly insoluble in water; it is neither dissolved nor disintegrated by the influence of rain or frost. Immersed in this glue, the eggshells remain compactly united together for years, like jewels set in some not very showy metal; a circular hole in the crown, when present, revealing the secret that the infant caterpillar has escaped. The united band or bracelet of eggs is as hard and as compact as porcelain; and when we reflect how feeble, how minute, how excessively soft, and how liable to injury is each infant caterpillar in its emergence from the eggshell, it is difficult to conceive by what means it escaped.

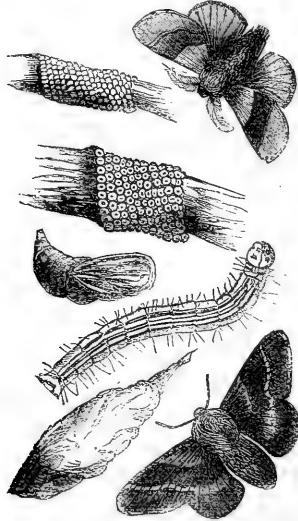

No sooner have the little dingy hirsute beings made their appearance and breathed the invigorating air than they set to work spinning and weaving, and very speedily indeed do they manage to construct a silken tent, and to enclose a few leaves of the apple tree, and on these they feed until entirely consumed. All the caterpillars contained in one band or bracelet of eggs unite in the construction of one tent, under which they reside in harmony, a happy family. As soon as the leaves originally inclosed are consumed, the caterpillars take in other leaves, which they consume in the same way; and so they go on, continually enlarging the field of operations, until the bough favoured by their selection presents the appearance of a disgusting mass of clammy web.

When about to change their skins—the process all caterpillars are doomed to undergo—they creep from under this tent, and each, fixing itself firmly on the outside by means of its claspers, crawls out of the skin that it has outgrown, and leaves it adhering to the roof of the dwelling. I have seen more than fifty of these cast-off habiliments decorating the roof of a single tent. It must not, however, be supposed that the lackeys continue very long under shelter of their tents. When they have grown old enough, and strong enough, and bold enough, they take advantage of the shades of evening to see—or perhaps, more correctly, to feel—a little more of the outer world. But then this difficulty occurs to them: "Supposing we wander about in the dark, how are we to find our way back at daybreak to this safe and comfortable retreat?" Who has not heard of "Rosamond's Bower," and the "labyrinth," and the "clue of silk?" Of course, caterpillars know all about it; and so, to guard against all possibility of losing his way home, each caterpillar before leaving home spins for his own guidance a silken clew; he produces it as he crawls, just as a boy's kite as it goes farther and farther takes out more and more string. It matters not how far he travels, or how tortuous his course; the clew he has provided remains where he left it, and by its guidance he can at any time find his way back to his bower through the labyrinth of leaves and twigs. After these experimental excursions the caterpillars rapidly increase in size, cease to live in company, and each enters on a solitary and independent state of existence.

In gardens, this species feeds on apple, plum, and many of our ornamental trees and shrubs, even including laurel, although this is a taste rarely exhibited, and we might have supposed, from the deadly effect of chopped or bruised laurel leaves on mothkind generally, that this would be a diet rather to be eschewed than chewed; and yet, so impartial is the lackey in the distribution of its favours, that it may occasionally be seen munching laurel, and weaving its web over the polished leaves as if it were the most innocuous dainty. As for standard roses, it will occasionally envelope them, if neglected, with such a mantle of web as to mystify the uninitiated gardener, and cause him to talk profoundly of the deleterious effect of east winds generally, and last night's frost in particular. In hedges it delights in the hawthorn, and in woods may occasionally be seen on aspen, alerce, hornbeam, elm, and beech.

When full-grown this caterpillar rests at length singly among the leaves and twigs, and if the tree or bough be shaken, it falls helplessly to the ground; it does not feign death, but immediately crawls to the stem of the tree or shrub whence it has fallen, and sets itself to reascend without loss of time; it never rolls in a ring, being of a feeble and flaccid habit, and betraying a most evident absence of vertebral column. The head is quite as broad as the second

segment; the body is long and almost uniformly cylindrical, but furnished with a conspicuous skin-fold all along each side just above the legs; the twelfth segment has a dorsal elevation, scarcely amounting to a hump; every part of the body emits fine soft hairs, but these are not sufficiently numerous to conceal the bright colours hereafter described. The head is bluish lead colour, with two conspicuous black spots on the forehead, which have a superficial but striking resemblance to eyes; the second segment of the body is dull orange, with two nearly square black spots on the back; the rest of the body is beautifully striped; there is a narrow stripe down the very middle of the back of a snowy whiteness, but bordered on each side with black; outside this on each side is a broader orange-coloured stripe, intersected throughout its length with black, and also bordered with black; this is followed by a broad side-stripe of a bluish lead-colour, sprinkled throughout with minute black dots; this broad stripe includes four large black spots; these are on the third, fourth, twelfth, and thirteenth segments, one on each. This is again followed by a narrow orange stripe, bordered with black; below this is a narrower and very irregular lead-coloured stripe, reticulated with black, and including the blackish spiracles; and below the spiracles is a faintly indicated and irregular orange stripe; the belly is smoky lead-coloured, variegated with black; the legs are black, and the claspers lead-coloured and paler towards the feet.

Transformations of the Lackey Moth.

About the middle of June this caterpillar ceases to feed, and wanders about for a while apparently aimless and objectless, but eventually takes up its station on some fence, railing, tree trunk, stone wall, or other durable object, or even spins together the leaves of its food-plant. In either case it forms a cocoon of yellow silk, the outer portion of which is loose and thin, the inner compact oval, and much resembling the cocoon of the common silkworm. This cocoon is remarkable, inasmuch as it contains a large quantity of a dry yellow powder a good deal resembling sulphur; the nature and object of this, and the source when it comes, have never been discovered, and I have attempted in vain to gain any information on these points. Within the cocoon, in six or eight days the caterpillar turns to a dark brown or even black chrysalis, without gloss, and beset with short brown hairs, which are particularly abundant towards the two extremities.

The moth appears on the wing in July, the males being smaller than the females. The fore wings are bright red, brown, or yellow, with two pale oblique transverse lines, the first being situated rather before the middle of the wing; the space between these oblique lines is frequently darker than the rest of the wing; the fringe is alternately pale and dark. The hind wings are red-brown, generally paler than the fore wings, and have an indistinct straight broad bar

across the middle. The head, thorax, and body are of the prevailing red-brown colour of the wing. It is a variable insect, scarcely two specimens being exactly alike. The male is distinguished from the female by having pectinated or fringed antennae.

The intermittent visits of this insect are very curious. Ten years ago, and indeed for many years previously, the few apple trees I possess were annually devastated by it, but subsequently to that date not a web was to be seen until 1866, when it again made its appearance. During the intervening years its destructive mission appears to have devolved upon the small ermine moth, *Yponomeuta padella*, which year after year completely stripped the apple trees. In 1866 the lackey returned in force, and this was not only the case at Peckham, but all the southern environs of London suffered from its visit; a correspondent of the *Entomologist* says that in the neighbourhood of Hornslow and Harlington its depredations were so extensive that considerable alarm existed among the market-gardeners lest the apple trees should be entirely denuded of their leaves, and the crop thus ruined. It may be worthy of notice that during this year they were particularly attracted by the better kinds of fruit, as Quarendens, King of the Pippins, Nonpareils, Keswick Codlings, Ribston Pippins, and Hawthorn-dens. Many thousand of the caterpillars were destroyed by shooting them with a mixture of sand and gunpowder, but no observation appears to have been made as to the effect of this treatment on the trees; and it will scarcely do to recommend a remedy which may prove too thorough.

It is certain that the egg bracelets are manufactured in early autumn, and it is equally certain that the eggs remain unhatched during the winter. I am unable to suggest a better remedy than shaking the boughs of the trees when the caterpillars are feeding, and picking them up as they fall limp and helpless to the ground, and this, it must be confessed, is very like locking the stable door when the steed is stolen; but this process carefully conducted must diminish the numbers for the ensuing year. Haworth says that poultry will devour the caterpillars with avidity if admitted while the operation of shaking down is in progress.—*Field.*

THE FLOWER GARDEN.

DESERTED FAVOURITES.—THE IRIS.

ANY flowers that may be justly termed "old garden favourites," are now either lost altogether or comparatively neglected. Among these the Iris stands in the first rank. It is not inferior even to the stately Lilies themselves. The distinct and pictorially graceful form of the corolla not only delighted the mere lovers of garden flowers, simply for its positive beauty, but has formed the model for graceful designs in many branches of decorative art. The Iris, for its beauty, has been worn as a badge by stalwart knights in the days of chivalry, as was the Genet, the Lily, and other flowers, often the last gift of some fair hand, and which, if worn under a fortunate star, and borne to victory, became permanent badges of a family or a city. Heraldic artists wrought the elegant form of the Iris into the exquisite device of the Florentine Lily, as it is called, into the adopted badge of Florence and of the Medici, and also into the three "Lilies" of France, gold on a field of azure; a device so long quartered with the arms of England. Flower-de-luce, or Fleur-de-lis, are both names inferring the plant to be a Lily—a kind of generic term by which the fairest and most stately flowers seem to have been distinguished from the "common people of the field," as a poet has styled the humbler flowers. "Behold the lilies of the field," is the exclamation of the Preacher on the Mount, "they toil not, neither do they spin, yet Solomon in all his glory was never arrayed like one of these." The conspicuous beauty of the Iris tribe leads to the inevitable conclusion that it must have been included among those "lilies of the field" with which the royal garments of Solomon were not deemed worthy of comparison; for in the glory of their spring-tide reign it may be said literally, and without exaggeration, that—

"Their cohorts are gleaming with purple and gold."

What floral effect in our garden scenery can be finer than a mass of the common purple Iris, such as that shown in the illustration on next page? Its erect leaves, like green sword-

blades, seem to protect the galaxy of gorgeous beauty which the profusion of flowers exhibit within and among the bristling defences; the contrast of that erect and massive assemblage of leaves, with the soft colours and elegance of the flowers is not one of the least charms of the exquisite Iris, which shares its name in common with the rainbow, the name given to it by Theophrastus, the eldest of the grand old race of early botanists, and which signifies, according to Plutarch, "the eye of heaven."

There is nothing more delightful than to lose oneself in dreams among the wild flowers that bloomed when the world was younger, and the graceful names which were given to them out of pure love for their beauty, and in dreaming and imagining all kinds of graceful stories of the fair hands that gathered them as the fairest gifts they could bestow on those they loved best, gifts to which jewels of gold would have been vulgar dross. There is nothing more delightful than such imaginary ramblings among the flowers of the past, except actual and active rambling, and trimming, and planning, and planting among the flowers of the present.

To the noble mass of purple Iris, so accurately represented in the annexed illustration, how pleasant it would be to add a noble group of Iris variegata in close juxtaposition, flashing its glittering contrast upon the royal purple of its neighbour—or, shall we divide the two with a noble clump of I. susiana, with its great bronze-pencilled flakes of erect petals?

Iris germanica.

But we must decide quickly, and stick to our decision firmly, or the choice, if we begin to hesitate, will become extremely difficult among the various charms of this beautiful and exclusive floral race. Its original species afford almost endless variety, both in form and colour, some bearing flowers both elegant and drooping. Such are the majority of the fibrous-rooted section of the family, others of the tuberous and bulbous-rooted kinds are crisp, glistening, and sculptural-like flowers carved in jasper or in opal. In colour, almost every shade and hue adorn these gorgeous flowers, from the most delicate agate to the richest and deepest purple, from the palest silvery yellow, like that of the rising moon, to the richest orange, with modifications of each of these leading hues varying sometimes to nearly pink, sometimes to dusky brown; and then the superadded markings, both in the original species and in the exquisite new varieties, are often so remarkable, that they at once rivet attention, and compel admiration, tempting one to compare them—here with the splendid sable slashes on the flank of the tiger—there with the exquisite brown embroidery of the skin of the hunting leopard—and, in some other charming flowers, to the cerulean mottlings on the wing of a jay. In short, how is it that the Iris family is not made a much more conspicuous garden feature? It presents a whole host of advantages—splendour of colour and form, endless variety, and a degree of hardiness in most of the species not exceeded by that of the wild

I. pseud-acorus, whose conspicuous flowers flock the waving sedges of our native brooks, with glittering dashes of golden yellow in the first weeks of May.

NOEL HUMPHREYS.

MY DAFFODIL GARDEN.

It is now upwards of two hundred and forty years since Parkinson described the Narcissus. At that period he found the nomenclature in great confusion. Since then Haworth has devoted much attention to the same subject and prepared a monograph of the genus; and within the last two years Mr. Baker, of Kew, has thrown it into sections.

Those who are interested in spring-flowering bulbs—and who is not?—could not do better than secure an entire collection of them, confining the more rare sorts to the select flower garden, and consigning those which can be purchased in large quantities at a moderate price to the wild garden, planting them amongst the grass, in the shrubberies, or wherever a floral display is a desideratum in the early spring months.

In treating of the contents of my bulb garden, I shall follow the sectional arrangement, and the first that presents itself is the Ajax of Haworth, or the Magnicorona section of Baker, with their time of blooming in the neighbourhood of London in 1872.

1. PSEUDO-NARCISSUS.—Crown deep primrose, divisions of the perianth sulphur. In flower end of February.

2. PSEUDO-NARCISSUS MINOR.—Similar to No. 1 in colour, but dwarfed and finer shaped as regards the flower, and in blossom at the same time.

3. PSEUDO-NARCISSUS MINIMUS.—Resembling in all respects No. 2, and flowering at the same time, but more slender and smaller in the flower. Height two to three inches.

4. SUTHERL.—I take this to be the Ovallaris; golden yellow, resembling the well-known Maximus, but in flower end of February.

5. MAXIMUS.—Golden yellow; in flower middle of March. Under this name I have grown major, lobularis, and propinquus; but the difference, if any, of the specimens in my grounds was trifling. I have reason, from one or two specimens of flowers sent to me, to suppose that there are, as in Pseudo-Narcissus, a gradation in the size of the flowers of this species, and I shall be glad if any one possessing such will send specimens to the office of THE GARDEN in exchange for others.

6. BICOLOR.—What I have grown under this name has a yellow crown, with the divisions of the perianth white; but the Rev. Mr. Ellacombe has sent me under this name a flower with a yellow crown and a sulphur perianth, and a flower such as I have described as bicolor under the name of Horsfieldi. Messrs. Backhouse, of York, a few years ago sent out two new Narcissi, counterparts of the two flowers sent to me by Mr. Ellacombe, but much larger. The one with the sulphur perianth they named Empress, and that with the white perianth, Emperor. This group is the most beautiful of the section. In flower third week of March.

7. CERNUS.—I have grown this also under the name of moschatus and albicans. If there is any distinction between them, it is very trifling. Colour, light sulphur, approaching to white. In flower third week of March.

8. CERNUS FLORE PLENO.—This is the double form of No. 7, and is scarce at present.

9. PSEUDO-NARCISSUS AUREUS ANGLICUS MAXIMUS (MASTER WILLMER'S GREAT DOUBLE DAFFODIL).—I give this name to the well-known double Daffodil on the authority of Parkinson (p. 101, fig. 7), and of this there is a lesser variety, which I have grown as minor flore pleno, not more than two-thirds the height. A flower which I have received from Mr. Ellacombe as plenissimus major I find described by Parkinson as "Pseudo-Narcissus maximus aureus, fine Roseus Tradescanti—John Tradescant's great Rose Daffodil." This latter is a monstrosity, apparently a number of flowers in one, as the specimen in question has several centres. This same variety is sold by the Dutchmen as Tradescanthus. The single forms of these varieties I have not been able to identify, unless it be that a flower which I met with in Covent Garden Market some days ago, as large as maximus, and of the sulphur colour of the divisions of the perianth in No. 8 is the single form. Information on this subject will be acceptable. The flower in question comes in with the double variety above named.

10. "QUEEN ANNE'S DAFFODIL."—This flower I received from Mr. Ellacombe. It is a double self-sulphur-coloured Narcissus. He thinks it is the double variety of Pseudo-Narcissus minor; but, to me it looks more like a small form of incomparabilis. I put it, however, in this section on Mr. Ellacombe's authority.

11. BULBOCODIUM, or CORBULARIA of some; yellow. A very distinct species, with rush-like foliage. In flower in May.

12. BULBOCODIUM TENUIFOLIUS.—This species has not yet flowered with me.

13. NARCISUS MINOR (OF LINNEUS).—This resembles *Pseudonarcissus minimus* in height and size, but is yellow throughout. Flowers beginning of March, and is a scarce species.

14. BULBOCODIUM MONOPHYLLUS.—A species recently introduced from Algiers, but not yet in commerce. The flowers resemble the yellow variety in all respects except in colour, which is a sulphur white.

P. BARR.

P.S.—Readers are invited to send specimens of flowers of anything uncommon.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Coleuses.—I have some old plants of these. Can I bed them out this season?—**Delta.**—[We would not advise you to retain your old plants for bedding purposes; place them at once in heat, and they will yield abundance of cuttings, which are very easily rooted under a bell-glass in a warm frame or pit. Coleus Verschaffeltii very effective out of doors. Coleuses require a temperature of 50° during winter.]

Amarantus salicifolius.—This beautiful Amarant is now so well known to most of our readers, that description is needless. We merely allude to it for the purpose of pointing out how it may be employed with best effect in the flower garden. The plant, in all respects, is extremely graceful, and is when well grown, fully furnished at the bottom; hence it will not be wise to use it as a central figure among a crowd of other subjects, unless they are very dwarf in stature. As an isolated plant, it will prove most effective; also as a vase plant, either indoors or out. As a "sub-tropical plant," it will, of course, prove very popular, and may be considered the most striking annual in that way.—H. V.

Sarracenia.—Kindly name the bit of Sarracenia I have sent you, adding at the same time the kind of treatment I must give it.—S. P.—[Your plant is Sarracenia purpurea. Towards the end of next month shake it out, removing some of the old soil, and re-pot in a mixture of sphagnum and peat; and bear in mind that good drainage is of the utmost importance. Give abundance of water at the root, and allow the pot to stand in a saucer of water. This plant is perfectly hardy, and its culture quite possible in the open air in England, either in the artificial bog or by the margin of ponds. A sunny position, with plenty of air, in a cool house, is then all that is required.]

Carnations and Pictées from Seed.—Permit me to advise your readers to make a trial of those collections of Carnation and Pictée seeds that are now offered by most of the principal seedsmen. They answer beautifully for mixed borders and cut flowers; few things except the Rose can equal them. There is an amount of vigour too about seedlings, that is absent in many of the named varieties; they will flourish in any ordinary garden soil, and a great proportion of the flowers will come double. There is also a considerable interest attached to raising seedlings, even when we know beforehand that there is not much chance of getting anything very superior from them, measured by a florist's standard of merit. To most people, however, a flower that is bright, sweet, and beautiful will give satisfaction.—H. W.

EARLY VIOLETS.

Horn through the blue of noon
The clouds move sweet with rain,
Fleecy, and white, and pure,
Sleep in a sunny plain,
While sudden drops are blown
And splinter on the pine.

O, for the April woods
That never shadows hold,
Fresh with the shining leaves,
Sweet with the odorous mould!
And O, for Primrose nooks
Of greenness starred with gold!

But dearer far than all
The broozy wold, where hide
In softly nestled nooks.
The violets, April's pride,
Of their own breath betrayed
Ere in sweet gloom desir'd.

And, season bright and brief,
Betwixt the bud and bloom,
Thoughts of thy violet nooks
Will darkest hours illumine,
Will yield thy brightness light,
And sweeten all thy gloom!

—Cassell's Magazine.

THE ARBOREUM.

HARDY TREES AND SHRUBS.

THE HEART-LEAVED CUCUMBER TREE (MAGNOLIA CORDATA).

This forms a handsome deciduous tree from thirty to forty feet high. In June and July, when decorated with its numerous tulip-like flowers, it makes a fine display, especially if planted singly on a lawn. It is a native of South Carolina and Upper Georgia, where it grows on the sunny banks of rivers; consequently it succeeds best when planted in a deep loamy soil and in a rather moist situation; but it will nevertheless thrive in any good garden soil, if not too dry in summer. It is increased by means of layers or imported seeds, the first of which reached this country in 1801. The leaves are alternate, and either broadly heart-shaped or ovately subcordate, entire, and on long footstalks; the upper surface is smooth and the under one tomentose, and they measure from four to six inches long, and from three to five inches broad; just before they fall off they become dark brown. The branches are rather stout, stiff, and somewhat erect, with the naked young wood hoary and brown. The flowers are yellow, terminal, solitary, erect, and from three to four inches in diameter, but they seldom expand fully. The petals are from six to nine in number, oblong and incurved, with their inner surface slightly streaked longitudinally by several reddish lines. The fruit is nearly cylindrical, three inches long and about three-quarters of an inch in diameter, and when young green, and very much resembling a gherkin or small cucumber, and hence the name; but when ripe, rose coloured and somewhat cone-shaped.

THE LONG-SPIKE FLOWERING PAVIA (PAVIA MACROSTACHYNA).

This forms an elegant deciduous small tree or large bush from ten to fifteen feet high, with several stems and stoloniferous shoots and slender spreading branches, whose extremities turn up, but whose points wherever they happen to rest on the soil root into it freely. It is a native of Georgia and South Carolina, where it grows on the banks of rivers. It succeeds in any good garden soil, but thrives best in deep loam, and in a situation which is rather damp. It is readily increased by means of layers. The Pavia macrostachya, which was introduced to our gardens in 1820, forms, when in flower, one of their chief floral ornaments. It produces long spikes of fragrant white blossoms in July and August, a season when nearly all other kinds of trees and shrubs are past flowering. The leaves are comparatively small, opposite, palmate, and set on long footstalks, with five oblong-lanceolate leaflets, which are bright green above, downy beneath, and distinctly stalked. The flower spikes, which are terminal, consist of blossoms having four erect narrow petals and numerous long projecting stamens, which give the spike a fringed appearance. The fruit is small and smooth, and is free from prickles. It has the following synonyms:—Æsculus parviflora, Pavia alba, edulis, and spicata.

GEORGE GORDON, A.L.S.

SEASIDE PLANTING.

In reply to "Marsh Bay" (p. 373), I can only state that the principal thing to be attended to in forming an ornamental plantation is, always to allow sufficient space for each of the permanent plants to develop its natural character. Therefore, instead of planting indiscriminately, as is so frequently done, plant upon a regular plan, and fill in with plants which can afterwards be cut back or removed as the permanent ones increase in size. Half the plantations formed for ornamental purposes are planted so thickly at first, and afterwards allowed to remain without thinning, until they are rendered comparatively useless. Large and small-growing trees and shrubs are intermixed without regard to proper position.

I must also caution "Marsh Bay" against what is misnamed cheap planting, that is, merely loosening the earth, and sticking the plants in holes barely large enough to receive their roots. He will find trenching and properly preparing the ground before planting to be, in the end, truly economy. With respect to the *Halimodendron* and *Euonymus*, both can be obtained from any nursery where a collection of hardy trees and shrubs is kept. "Marsh Bay" should plant the common evergreen oak, which he will find to be decidedly one of the best trees for this purpose.

GEORGE GORDON, A.L.S.

"THE BIG BARKED TREE."

"The Big Tree," *Sequoia (Wellingtonia) gigantea*, from which the bark was stripped to the height of 116 feet some few years ago, for exhibition in Europe, is still standing in the famous Calaveras Grove. When first discovered, this grove contained more than a hundred such trees, the largest of which towered to the extraordinary height of 325 feet, while the least of them reached an altitude of 231 feet. The diameter of the trunk, six feet above the ground, was fifteen feet in the largest, giving a circumference of forty-five feet, and over ten feet in the smallest of these enormous trees. The accompanying woodcut is a faithful portrait of the barked giant. It is the third in regard to size in the Calaveras Grove, and, like its big relatives, it has received a distinctive name, which is, "Mother of the Forest." The largest specimen of *Sequoia* in this grove is honoured with the name of "Keystone State," and the second, which is 319 feet in height, is called "General Jackson." The bark of the "Mother of the Forest," put up in the form in which it grew, was exhibited in many places in America before it reached Europe, and eventually found what promised to be a permanent resting-place in the Crystal Palace. It might indeed have proved so, but for the occurrence of the ever-to-be-regretted fire which destroyed so many objects of interest, and, among others, the colossal shell of the "Mother of the Forest." It will be interesting to observe the effect of the barking of this enormous tree, and to ascertain whether or not, Nature will be able to replace the bark stripped off. It was proposed some few years ago to bark the trees of the Boulevard des Italiens, at Paris, in order to get rid of numerous colonies of a small bark-feeding beetle, whose ravages threatened to destroy the trees. Experiments of the kind having been tried elsewhere with entire success, a trial upon the trees of the Boulevard was resolved on. It was objected at the time, that, while the destruction of the trees by the ravages of the beetle was slow, and by no means certain, the barking system would prove almost immediately fatal. In support of this assertion it was argued that the ringing process was one resorted to for killing trees

where forest clearings were being effected, and was fatally certain in its results. The answer was this, that the ringing system, to be successful, must cut through the soft coating of inner bark next the ripened wood, as well as the hard external bark, which, in such barking as that resorted to in the case of the "Mother of the Forest," or in that about to be adopted to get rid of the bark beetles in question, the soft inner bark may be left unbroken and in a condition to develop itself into a hard protective coating over the next year's formation of new bark.

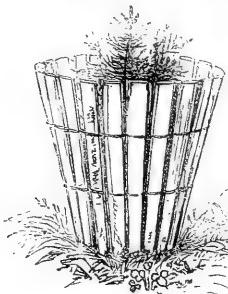

Our figure serves to indicate the amazing stature of a full grown *Sequoia* in comparison with other conifers, many of which, measured by the same scale, are from eighty to a hundred feet high. A *Sequoia* of still greater dimensions was cut down about the time when the barking of the "Mother of the Forest" occurred, and if the last-named should perish from the loss of its magnificently thick overcoat, two of the veterans of the Calaveras Grove will have perished prematurely by the hand of man, after a life of some fifteen or twenty centuries, which might otherwise have defied the wear and tear of time for still a few centuries more. Several have fallen since the first discovery of the grove in 1852, just twenty years ago, which has tended to reduce still more the number of these patriarchs of the forest, but a considerable number of young trees, in different stages of growth, are coming on in the outskirts of the grove. It has been considered that *Sequoia (Wellingtonia) gigantea* will not attain gigantic size in this country; and that opinion is founded upon the observed fact that while the health of the trees raised from seed in England is exuberant, and their growth rapid during their early years (in fact, till they attain a height of twenty or thirty feet), after that they appear suddenly checked, and make but little progress, the leader appearing less and less vigorous every year. This, however, may be the nature of the tree; which in its native climate makes much more rapid growth in its early years than afterwards. If this were not so, and its early growth at the rate of from one to two feet each year were continuous, the tree whose age-rings indicate an existence, say of 1,300 years, ought to be more than a thousand feet high, instead of

from 300 to 330 feet, which appears to be the limit of its growth. If there be anything in this argument, our descendants may perhaps behold in this country towering Sequoias as gigantic as those of California.

H. N. H.

CHEAP TREE GUARD.

A CLEAR, easily erected tree guard has been long a want to gentlemen who plant a considerable number of specimen trees in woods and other places where cattle cannot get at them. We use one here which has many advantages; it is cheap, put up in a few minutes, and not only guards the young plant from damage by rabbits and hares, but gives it, for the first few years after planting, protection from wind. We get palings cut at the sawmill three feet long, two inches wide, and three-eighths of an inch thick; these, slightly pointed, are driven into the ground all round the young tree, the tops gradually sloping outwards. We then twist strands of tarred cord in and out between the palings; this makes it exceedingly firm, and it will require no further attention as long as the paling lasts.

Tree Guard.

When we first began to put up these guards we used unravelled strands of galvanised wire fencing rope, which makes perhaps a stronger job; but the tanned cord is quite enough. We send any rubbish to cut into palings to the sawmills—remains of slabs left when cutting post and rails, spruce fir (fit for little else), or any waste wood pretty free from knots. If in a very exposed situation, one stronger paling can be used (part of a rail), and by driving it further into the ground any chance of the wind blowing the whole thing over would be prevented, otherwise the palings merely want a very slight tap to fix them firm enough; though from the palings being inclined outwards there is considerable space between the tops of them, still no rabbit dare leap in.

It takes from sixteen to twenty palings to each guard, according to the size of the plant to be protected; thus, at 2s. 6d. per hundred feet of sawing, they will cost, all told, labour included, about 6d. each, whereas the cheapest wire netting tree guard will be 1s. 6d., the same size; and if made of strong wire they would cost 2s. 6d., making a considerable saving, if a quantity of young pines have to be planted out.—*A Soldier, in "Field."*

DRAINAGE.

(Concluded from page 363.)

INCLINATIONS OR SLOPES OF DRAINS.

OWING to the constantly varying slopes of the country, scarcely any rule can be absolutely laid down for the inclinations at which the pipes should be laid. The greatest attention is required in laying the main pipes, into which the smaller branch pipes run. In flat countries they should always be set out with the spirit level, and the depths from the surface given to the men at every one or two chains along the line. Water will run freely at inclinations of one foot fall to one thousand, two thousand, or three thousand feet of length, where the pipes are well laid; but it must be observed that at every junction of a branch pipe the flow will be impeded in the main pipe by the water entering from the branch pipe, sometimes running with considerable velocity. So that as much inclination as possible should be given to the mains, in order that the hydraulic pressure may force the current towards the outlet. The inclinations of the minor or branch pipes

must, necessarily, be controlled by the natural slopes of the ground. In a general system, laid out on a definite plan, it is better to have as few outlets as possible, and I need hardly say that all the minor or branch pipe drains ought, at their lowest ends, to be united or joined up to one main pipe of such larger dimensions as may be proportioned to, and capable of discharging the water from a given area of land; these larger pipes being conducted to the lowest extremity of the area to be drained, and there discharged into an open drain or stream. The cost of long lengths of large pipes, increasing in size as they go, raises a question as to the expediency of using them; but the work is easier to maintain than when a large number of outlets is used. I have frequently found it most useful, in laying both large and small pipes, where the bottoms of drains are in soft, boggy, or sandy soils, and there is every probability of the pipes sinking or getting out of their proper inclination, to lay them on strips of wood cut out of three planks of elm, or other timber as durable in water, from $\frac{1}{2}$ inch to $\frac{3}{4}$ inch thick. The cost is very trifling, and is as nothing compared to that of having to re-open and re-lay the drains, while doubt of the success of the work is thereby to a great extent avoided.

OUTLETS.

The pipe at the outlet or head should be raised above the ditch or stream, which should be cleared, and, if required, deepened for some distance, so as to ensure the water not being backed up into the pipes. I have adopted self-acting iron traps at the outlets, in cases where the tide has occasionally risen against them; but the chief object was to prevent the mud, of which there is generally a large quantity in tidal waters, from being taken up the pipes, and there left to deposit itself. All outlets should be protected by brick or stonework, set in mortar or cement, the foundations being sunk from one to two feet under the bottom of the ditch or stream, which should be paved to receive the water from the pipe. Referring again to the depths of the drains, it is frequently necessary to lay the main drains six, seven, eight, or even ten feet deep in places, in order to drain land to an outfall which lies at too low a level to allow of the ordinary depths being employed.

SIZES OF PIPES FOR CERTAIN AREAS.

In the early period of land drainage, pipes of one inch in diameter were commonly used, but they were not continued for any length of time, and they were seldom, if ever, sunk in the ground deeper than two feet or two feet six inches. Pipes of $1\frac{1}{2}$ inch diameter succeeded them, and more recently, two-inch pipes have been almost universally adopted for the branch drains. There was also the horseshoe pipe, laid on a tile as a sole; but these have totally failed and become obsolete. The adoption of two-inch pipes (the area of which is 3 1/4 square inches), has been a great improvement, inasmuch as, besides being in nearly all cases large enough for the water to run out, they allow the air to pass up when they are not full, and thus ameliorate the condition of the soil above and around them. No single rule can apply as to size; but, as regards the sizes of main pipes, into which the minor pipes discharge, some attention is required to regulate them, and, if possible, their inclinations. These main pipes vary from three inches up to twelve inches, and two feet in diameter, in proportion to the area which will discharge into them, and the inclinations at which they are laid. The several degrees of porosity of soils between the extremes, must be treated as experience may dictate, and the inclination at which the drains are laid will affect the question; for instance, a rapid fall of the branch pipes into the main pipe would necessarily require that the latter should be increased in size; but a slow discharge does not require larger pipes than twelve inches in diameter.

DIRECTIONS OF DRAINS.

In uniform soils, whether dense or free, the usual practice is to lay drains parallel to each other, on what is commonly called the *gridiron system*. In stiff clays, where the drains are more frequent, this plan is undoubtedly to be preferred, for the reasons before stated—that the water may be equally drawn off from all parts, and the land uniformly aerated. In free soils, such as gravel, sand, and the like, where there are springs which rise to the surface, and are visibly saturating

large or small areas, the drains may be run in such directions as will enable them to tap those places, and ultimately to drain a larger area.

ROOT CHOKING.

Deep as drainage may be laid, it is never altogether free from the possibility of being put out of order by the roots of trees, or of certain kinds of crops which may penetrate the drains, and form a hindrance to the free passage of the water through them. The roots of the elm, ash, willow, and other trees, are known to enter the pipes, and even pass through the ground for several yards to reach them, as if they were attracted by the moisture and air which they find in the pipes, and by the nourishment afforded them there. To obviate this difficulty it is advisable, where it occurs or is apprehended, to use socket-pipes jointed with cement, or to lay the pipes as far as possible from the trees. I have found that embedding the pipes in lime, mortar, or concrete, has prevented them from being choked, although close to trees which it was impossible to avoid, and has kept them clear for some years. The roots of some crops, if they should penetrate the pipes, die away when the crops are removed, and are frequently washed out at the mouths of the drains by the strong flow of water through them. Other substances give the drainer a vast amount of trouble in obstructing pipes. Ochreous water, depositing oxide of iron, is a common source of obstruction. It appears to harden and consolidate as it receives air through the pipes, and ultimately chokes them. I have found it best to get at the source of the spring or springs, and conduct the water away by large pipes independent of the general system. Confervo and parasitic plants will also get into the pipes, grow, and ultimately stop the flow of water through them; another source of trouble is the percolation of sand into the pipes, which necessitates patience and care in taking them up frequently after being first laid and relaid, until all the water has run out of the bed, and then laying them in straw and on strips of wood.

COST.

This must vary in different parts of the kingdom, according to the soil, the rate and quality of the labour for this kind of work, the seasons, and the price, quality, and cost of carriage of the pipes. Sometimes the cheapness of one or two of these items will counteract the dearness of the others, so that something like an average may be arrived at. I have kept a register for some years past, which shows the rate of cost per acre and per rod of drainage works, executed under my supervision, in localities distributed over a large part of the kingdom. This summary includes about 120 distinct works, representing every variety of soil, every degree of difficulty, and ranging in quantity from 10 to 1,900 acres. The rates of cost extend from £3. 6s. 8d. to £9. 5s. 4d. per acre, and from 14 to 36 pence per rod, whilst the number of rods of drains to the acre varies from 39 to 115. Where the rate per rod is high, the rate per acre may be low, and vice versa. I have arranged the following table, which gives the general prices of work under the various conditions —

Ordinary cost of cutting and filling minor drains, using 2-in. pipes at, say 2s. per. 1,000.

Depth.	Rate per Rod for Cutting and Filling.	Rate per Rod for Pipes.	Total.
4 feet	0 8	0 5	1 1
5 "	0 10	0 5	1 3
6 "	1 1	0 5	1 6

DURATION OF PIPE DRAINAGE.

This depends almost entirely on the manufacture of the pipes. Where all the work has been well done, drainage executed thirty years ago is known to be in an efficient condition, although pipes were not then so deeply laid as they are now, and it may be fully expected that the deeper they are laid the less liable they will be to be injured or disturbed — a strong argument in favour of deep draining. I may add that farm bailiffs, who have other work to attend to, ought never to be employed to superintend drainage, as it requires the whole

attention of the foreman to conduct a work cheaply and securely, and it is only men who are specially trained in drainage construction who can properly superintend it. There should not be larger bodies of men than from thirty to forty under one man's charge. Another practice which should be condemned by all who are interested in the success of these works is that of giving pipes to tenants to lay themselves. Such work is never well done, and is just so much money thrown away.

R. B. GRANTHAM, C.E.

One of the members who was present at the meeting when the above paper was read said he would be glad to have more precise and detailed reasons for the assumption that four feet should be the minimum depth for draining in stiff clay soils. There were to be found intelligent men possessing a practical knowledge of the subject, who concurred in saying that from three feet to three feet six inches was deep enough; and many could point to drainage work done four feet which was said to have proved a failure. Between the two opinions he had had some difficulty in deciding which was the right one. He was speaking of the stiffest clay soils only. In attempting to decide which was the proper depth, he had come to two conclusions: — One was, that four feet drains, if near enough together, were always quite satisfactory; the other, that if it were attempted to make deep as economical as shallower draining, by putting the drains further apart, the result was apt to be unsatisfactory. If a stiff piece of land were drained three feet deep and eight yards apart, the result was tolerably good; if, however, it were drained four feet deep and twelve yards apart, a wet piece was apt to be left in the middle. To drain eight yards apart and four feet deep would, of course, be additionally expensive.

NEW, RARE, OR NEGLECTED PLANTS.

EURYCLE AMBOINENSIS.

A DISTINCT and valuable Eucharis-like stove bulb, producing pure white flowers in large showy umbels, on stems from fifteen inches to two feet high. It flowers freely in early spring, and placed among ferns here and there has a charming effect. It flowers the better for being dried off after blooming and making a good growth, and in other respects will succeed with the treatment usually given to that now popular stove plant, the Eucharis amazonica. It is a native of the islands of the Eastern Archipelago, the Philippines, &c. Its leaves are roundish-cordate, concave, strongly-nerved, and pale green. The perianth is about three inches long, including the tube, the limb spreading, and the corona white, about three times shorter than the limb, and having twelve marginal teeth, two between each of the six stamens.

GILIA LINIFLORA.

The genus Gilia is already represented in our gardens by numerous handsome varieties, but this one is quite different from any yet cultivated. It forms bushes which are very much branched and dwarf; the branches being very slender and the leaves narrow and elegant; the whole plant being completely covered in the flowering season with large blossoms, like those of Phlox Drummondii or a large Linum, of a pure white, with yellow stamens. It is a charming acquisition for groups, edgings, and contrasts; and if required to flower in the end of spring, should be sown in autumn, and the seedlings kept under cover during the winter; but for summer flowering, it should be sown in March or April of the same year.

MATRICARIA EXIMIA GRANDIFLORA.

This fine and remarkable variety, which reproduces itself freely from seed, and which, when sown early in spring (March and April), and planted out when a few leaves have grown on the seedlings, flowers abundantly (even in the first year) throughout the summer, and until the first frosts appear. The flowers, which are very double, and as large again as those of the old Matricaria eximia, and also fuller, are of a very pure white. They are particularly adapted for bouquets, and as the plant is exceedingly floriferous and vigorous, it cannot fail to be much in request for flower beds and groups. Its height varies according to the soil (which should be sweet and well-drained), from twenty inches to two feet, but by means of judicious pinching it may be kept dwarfer, should that be desired. — *Revue Horticole.*

GODETIA NIVERTIANA.

ENOTHERAS are beginning to be very generally cultivated in all private gardens, from which annuals are not excluded to make room for what are called bedding-plants. This new variety, named after

its raiser, M. Nivert, is remarkable for its large, widely-cup-shaped, erect flowers, which are white (seldom flesh-coloured, like those of G. Schauinrich), with a large spot of bright carmine (sometimes cherry colour) at the base of each petal, producing a fine effect. The usual culture and treatment for annuals is all that is required for these plants.

(*To be continued.*)

THE KITCHEN GARDEN.

THE CUCUMBER—ITS CULTIVATION AND USES.

The Cucumber is a native of the East Indies, and is said to have been introduced to British gardens in 1573. Whether at that early period it was cultivated for culinary purposes or not we have no means of ascertaining, but certain it is, that so recently as the commencement of the present century, its cultivation for early use—say to cut in March—was regarded as a masterpiece of the gardener's art. Then its growth was confined almost exclusively to small frames placed upon a bed of fermenting material, such as stable dung, leaves, &c., or it was cultivated in brick pits, heated by the same materials. The original species was a short, thick, rather warty fruit, closely covered with spines. It rarely exceeded four to six inches in length, and was produced in clusters of from four to six at a joint. From this, nevertheless, all the long Cucumbers of our gardens have sprung—a bright example of the enabling influence of cultivation, and even now an inducement to us to try and improve other unpromising subjects in a similar manner. In our early days the best grown Cucumbers rarely exceeded a foot to eighteen inches in length, the varieties being few, and known by such names as Long or Short Prickly, Patrick's Frame, Flanagan's Early, &c. Still such as these and other varieties continued to improve, and by sowing seed from the largest and handsomest fruit our present kinds have come into cultivation. The Manchester gardeners were, we think, the first to devote attention to the production of Long kinds; and to Mr. Walker, a gentleman of that town, belongs the credit of raising some of the longest and most useful varieties. Walker's Black and Walker's White Spine, thirty to forty years ago, were special favourites, growing to the length of twenty to thirty inches without losing much of the proportion necessary to suit them for table use. Then Mr. Hamilton, of the same neighbourhood, but now of Stockport, was, and is, a very successful raiser of the long kinds; and here (at Nottingham), as coeval with the date referred to, may be mentioned the variety called Pearson's Long Gun, still grown exclusively by Mr. J. R. Pearson, of Chilwell, and certainly one of the largest and best flavoured varieties in cultivation. This kind is much esteemed by cooks for stewing.

SMOOTH VARIETIES OF CUCUMBER.

About the period above adverted to, the Smyrna, a nearly smooth pale green variety, and the White Turkey, a yellowish white kind with strong black spines, came into cultivation; and we well remember the surprise which a fruit of the latter occasioned in our market when first exposed there for sale. "Had it been blanched?" "Was it fit to eat?" and other questions followed, while few felt disposed to put its eating qualities to the test, as it remained unsold at the close of the market. From these two varieties, crossed with the prickly kinds, originated, after a few years' cross-breeding, the Sion House or Lord Kenyon's Favourite, said by some to be raised at Sion House, near Brentford, and by others at Lord Kenyon's seat in Yorkshire; while some contended that they were distinct varieties, and if so, both claimants were entitled to the credit of raising them. The difference, if any, was external, and we have always had the impression that Lord Kenyon's was in colour a much darker green. Be that as it may, the two varieties may be said to have been identical in their good qualities—vigorous constitution, hardiness, prolificacy, and, above all, fine flavour and suitability for cultivation in winter. The same qualities still apply to the Sion House, so much so, that at the present time there are many connoisseurs in the country who will not allow any other kind to be grown in their gardens, or be sent to their tables. In this they are quite right, for we have never tasted any variety

equal to it in flavour, Pearson's Long Gun being the next. From the Sion House has sprung the Telegraph, now a most popular favourite, and many other varieties of similar character. If we were called upon to name the two most useful cucumbers in cultivation, we certainly could not pass over the Sion House and Telegraph, nor do we expect they will ever, for table use, be surpassed. Of the character of Sion House, short but very prolific and good flavoured, may be mentioned Munroe's Prolific or Rabley, Master's Prolific, Glory of Hants, and one recently brought into notice by Mr. Dean, late of Shipley, near Bradford, viz., Dean's Winter Prolific. This is represented to be a very excellent variety for winter forcing, large enough for private use, hardy, and, as its name implies, very prolific. The long varieties of Cucumber are rarely free bearers, not continuous, and generally cease bearing much sooner than the more moderate growing kinds. From a well-established plant of the Sion House, say twenty feet long, and strong in proportion, we have frequently seen, in the height of the season, twenty to thirty fruit per week cut; while, on one occasion, we saw forty feet of Cucumbers, varying from nine to eighteen inches each, cut at one time from one plant. The plant in question was not less than twenty feet in length, strong in proportion, with a stem six to seven inches in circumference at the surface of the soil. For this reason, and for family use, we say grow the short or medium varieties; they will give fruit every day, while the long kinds will sometimes be quite destitute of fruit. With these remarks we must close our history of the origin of the cultivated Cucumber, merely remarking that if we are wrong in our estimate we shall be happy to be corrected.

SOILS.

The Cucumber is not a fastidious plant in its choice of soils. It will grow in almost any soil that is free, open, and moderately rich, but, of course, there are soils, or rather composts, which when properly prepared, are more suitable to its perfect growth than others. Mills, who wrote upon this subject some thirty years ago, recommended especially for its growth in winter a light porous peat. In that, as he grew the plants either in dung heated pits, or upon hot beds composed of the same material, he was quite right. With such a heating material there must be a large and constant generation of ammonia, and the peat in itself, being poor, would absorb and fix a large portion of that gas which, though necessary to the perfect growth of the plant, is, when present in excess, highly injurious to vegetation of all kinds. Hamilton, a very successful grower, proposes a preparation of loam, rotten dung, and leaf mould in proper proportions, pressed between the hands into compact balls. These he recommends to be placed in layers upon the surface of the soil, and, of course, in close contact with the roots, the object being, as explained by him, to get the largest quantity of rich pabulum into the smallest possible space. Others prefer pure turf loam, leaf mould, or even decayed mushroom dung. Some of the finest crops we ever saw were grown in the latter material, and moss in alternate layers, a system that will be explained in detail in another chapter. For choice, we prefer a light turf loam from an old sheep pasture or the face of a rock, with the grass on, cut about two inches thick, when the ground is in a dry and healthy condition. This should be stacked in a narrow ridge, but quite waterproof, for some months prior to its being used for the plants, so that the fibre may be in a decaying condition. This soil should be of tough, rooty nature, so that it may be thrown about for a long time without the soil being knocked out of it. In this the Cucumber delights to root, and it will be found rich in nutrient.

If there is not time for the preceding preparation take the turf fresh from the field, and chopping it into pieces from four to six inches square, prepare a fire with any pieces of wood that may be about, augmented by such old pea sticks, prunings of trees, brush wood, and similar material, packing it into a close compact cone, but leaving a space at the bottom through which it may be lighted. Then take the chopped turf and pack it upon the fire cone nine to twelve inches thick, and cover the whole with litter of some kind to throw off the rain should any fall. The fire may then be lighted, forming a vent for the smoke by thrusting a stake or crowbar through the soil at the apex of the cone. When the fire is fairly established the vents may be stopped up, as the object is to char or

thoroughly heat the soil through, and not to burn it. When the fire is exhausted, and the mass cooled down sufficiently, open the heap and pick the charcoal out and mix the smaller pieces and the ashes with the charred soil; this, of itself, would grow the Cucumber excellently, but mixed with about one-third of half-decayed leaf mould or dung it forms an unexceptionable compost. To the decayed turf first mentioned, the same proportion of dung or leaf mould may be added; but previously to mixing, it will be wise to sprinkle the heap with soot in the proportion of half-a-pint to each bushel of soil. Then mix all together, taking care not to break the pieces of turf smaller than a large hen's egg, and it will be in a fit state for use.

CUCUMBERS IN MOSS.

The cucumber may be very successfully grown in fresh moss, or, where it can be procured plentifully, in sphagnum or bog moss. This must be procured, and before using it should be subjected to sufficient heat to destroy any grubs, snails, insect larva, or seeds that may be in it. This may be effected by placing the moss on the top of a hot flue or hot-water boiler, or it may be scalded and then dried, but that is a slow and unnecessary process—simple heating will be sufficient. The moss will be used in alternate layers with leaf mould or decayed mushroom dung, as will be described hereafter.

MANURES.

Of these there is nothing better than old, decayed cow dung reduced to a fine mould, but as this cannot always be procured, a good substitute may be extemporised by placing recent cow dung upon a hot flue until it is thoroughly dried. This, when broken into pieces about the size of walnuts, will be found, when mixed with the turfy soil, an excellent stimulant. Of stronger manures, a few bushels of sheep's or deer's dung should always be at hand to make, with soot and fresh horse dung, manure water.

(To be continued.)

GARDEN DESIGN.

THE BOIS DE VINCENNES.

By EDOUARD ANDRÉ.

The Bois or Park of Vincennes is the great eastern promenade of Paris, as the Wood of Boulogne is that of the west, and les Buttes Chaumont that of the north. Had it not been for late events, the park of the south, called Montsouris, would have been finished, and thus would have completed the graceful quadrilateral of shades, verdure, and flowers, which so agreeably surrounds Paris.

The River Marne waters the base of the Bois de Vincennes, which rises to it from the summit of a plateau terminated by a steep hill. The extensive views from this point upon a vast horizon, comprise St. Maur, Creteil, Charenton, St. Maurice, and Joinville—all those charming villages, so esteemed by the young Parisians—by the rowers of both sexes—the artisan and the workman, who there find a resort for enjoyment to the extent of their moderate resources, and which has given to the shades of Vincennes the name of "Bois du Peuple." Vegetation there is more abundant and more vigorous than in the Bois de Boulogne; the embellishments have been carried out with more harmony, with a larger expansion of ideas, and means; and in point of landscape also the Bois de Vincennes is superior.

The works have been divided into two distinct parts. In the neighbourhood of St. Mandé, which abuts upon the ancient dungeons of Vincennes, yet existing after having gone through a history so fertile with tragical events, close to the station of St. Mandé and the Avenue of Vincennes, which leads from the Barrière du Trône, a point of cheerful landscape presents itself, arranged with most pleasant taste. It is the Lake of St. Mandé and its environs. At the bottom of a hollow, formerly dark and dried up, the waters of the high ground of the wood have been brought together into a reservoir, afterwards being pumped into the Marne. In the middle of the lake a large island of poplars is reflected in the clear water; paths wind round the sides of the hill, rocks overhang the head of the pedestrian, and this ensemble, fringed by a green girdle of vigorous trees, gives one the sensation of an enchanted spot.

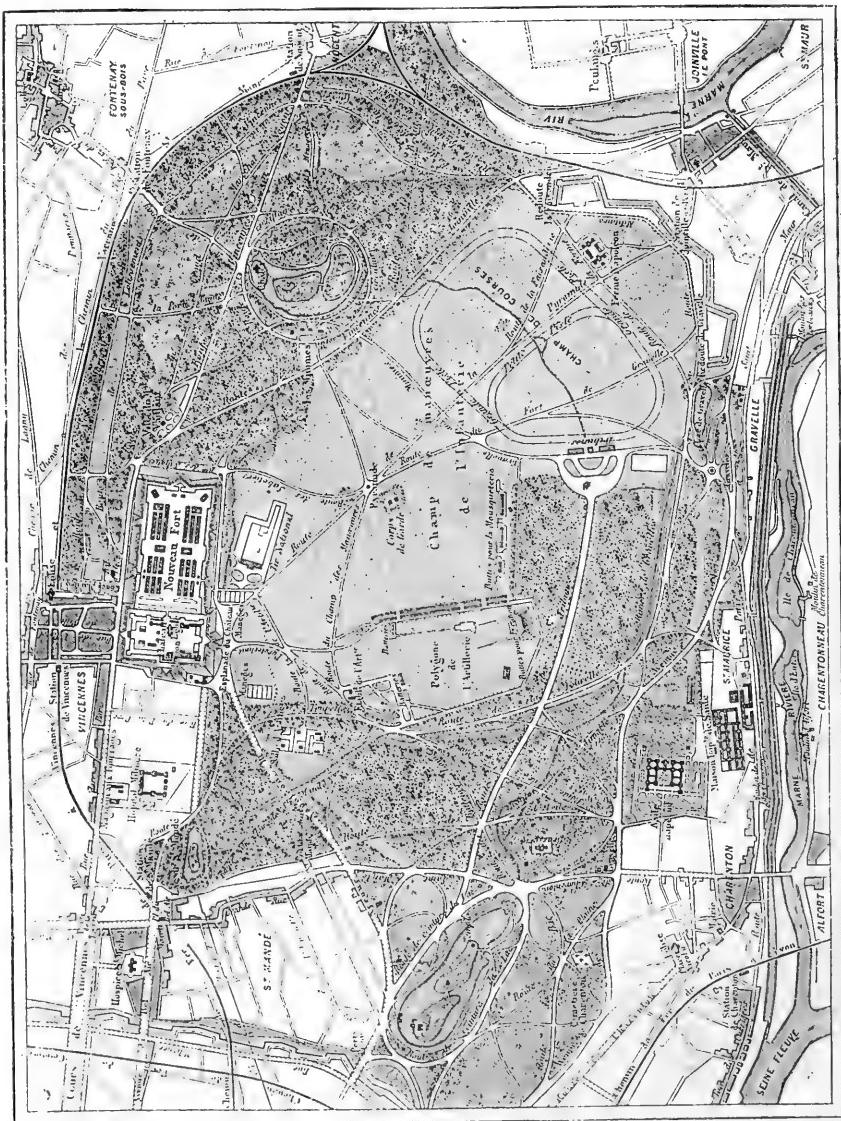

If, from the little Lake of St. Mandé, we pursue our walk on foot, by ascending the little rivulet, we shall pass over the Avenue Napoleon III., which leads from the fort to the Plain of Charenton;

and passing by the Pyrotechnic School, inclosed in a dense clump of trees, we come out upon the plain, where the artillery exercise their manœuvres. Here there is nothing but barren fields of vast extent occupied by butts for cannon practice; but further on is the Hippodrome, where the races take place, in imitation of those of England, which have become so popular in France. From this point is seen in the distance, through a vista of trees, the Pyramid; and further on that part of the Wood of Minimes and the Napoleon Farm which reaches the counterfort of the Redoubt of Gravelle above the Marne. But, in taking an oblique course to the right, and still ascending the rivulet, which winds, and here and there rebounds upon the rocky points, you arrive at the summit of the plateau of Gravelle, which looks down upon the Marne, and where a restaurant, much esteemed for its extent and the variety of its views, attracts daily a great number of visitors—lovers of a fine prospect. The little Lake of Gravelle, which serves as a reservoir for the water drawn from the Marne by means of an immense steam pump, leads us close to the farm arranged by the ex-Emporer, where the buildings, designed with much taste, contain comfortable accommodation for those visitors who come to partake of the milk. The walk continues up to the Lake of the Minimes. There embellishments have been carried out already on this charming spot, well known, under the name of La Sorte Jaune, to Parisian pedestrians, and where numerous restaurants attract on Sundays many visitors. The lake is sufficiently extensive for boating, the three islands it contains are full of shade and freshness, and the Nogent Station, close by, renders easy access to it. The wood is there very thick. It is composed of massive clumps of oak and beech trees, to which are added conifers, lightened up here and there by judicious openings. That part of the wood between Gravelle and the Donjon which bounds the railway has been cut off from the main park by the city of Paris having bought up the wood; and there establishments for entertainment have been constructed within the last few years.

At present we have only alluded to those parts of the wood penetrated by strategic roads, or by the great roads of communication which existed prior to the improvements, and which it was necessary to maintain. The landscape architects of the city of Paris (of whom I formed one at that period), under the direction of Messrs. Haussmann and Alphand, without altering the general design of the wood, could only enter into secondary modifications. So that, in a landscape point of view, the effects obtained have been but partial, and more than one defect may be noticed; but the difficulties and trammels imposed by its original situation must be taken into account.

It is not the same with the new portion of the wood, called the Plain of Charenton, which extends between the fortifications of Paris, that part comprised between the gates of Charenton, Rueille, and Picpus, the base of St. Mandé, the Imperial Asylum, and the road from Paris to Charenton. It was, even in 1865, a sterile plain, where only thistles and nettles flourished. We must freely admit that now it is the most beautiful part of the wood. A lake, upwards of twenty-five acres in extent, with two large islands connected by two bridges, ornamented by a temple, rocks, and well-planned clumps of trees, occupy the central part. The area of this new park altogether is more than one hundred and eighty acres. It was finished in two years. The plan of it is extensive, well conceived, vastly developed, the views well preserved, and of sufficient extent. The works of the canal and rock construction, directed by Com. Dausen, are remarkable in more ways than one. The great Avenue Dausen, which forms the principal route from Paris to the new park, and which stretches from the Place de la Bastille to the Picpus Gate, is truly majestic by its width of forty-four yards, its length of several miles, and its double row of beautiful plane trees.

Everybody admits the vastness of the landscape conception of this grand wood. If one, however, could be captiously critical it would be, in our opinion, upon the plantation. Large clumps of trees have been planted; and, in order to add to the grandeur which it was sought to attain, many trees of the same kind have been planted there, reckoning upon the effect of uniform colour to produce an harmonious result. The underwoods have been planted in the same manner—one or two kinds only in certain parts. However, we find that a contrary effect has been produced to what had been desired. A uniform clump of Austrian pines is very large when covering eleven hundred or twenty-two hundred square yards but trifling for an area of some thousand acres. In order to create perfect harmony it was essential to plant the Plain of Charenton with a depth of forest uniform in all its points, and which time alone can improve, and to work out this with five or six kinds of trees, equally mixed throughout, and to reserve only for the inner portion some rare groups of choice plants, which would, above all, throw out signs of vigour, and form a harmonious background.

PLAN OF THE PARK OF VINCENNES.

LAKE VIEW IN THE PARK OF VINCENNES.

THE HOUSEHOLD.

SALADS.

(Concluded from page 383.)

It is in the proportion of the ingredients which are used to make the dressing or sauce of the salad that lies the great difficulty. A Spanish proverb says that, to make a good salad, a miser should pour out the vinegar, a spendthrift the oil, a wise man the pepper and salt, and a madman should turn it—*travailler* is the technical expression. This may give some idea of the principle upon which one is to mix a salad; but oil, vinegar, pepper, and salt, are not the only things which are used to produce what I should call a good salad, and to make one such it will take not only a wise man, but a practical one as well, with plenty of experience in his business. What I have often said before of cooking apples applies still more forcibly to salad-making, for in this you have no action of the fire, which sometimes corrects the mistakes of the operator; it is like fresco-painting and oil-painting—once you have mixed your salad, there it is, for better or for worse. A sauce or a ragout you may modify, correct, and alter in many ways as you go on; a salad you cannot, without making a mess of the whole thing, once you have mixed the greenmeat with the dressing. Practice is the only master to learn salad-making of. I do not pretend to teach anyone to make salads. All I can do, is to point out to those who wish to become adepts in the art how to set about it.

Oil, which plays the most important part in the business, should be of the very finest quality, but it ought by no means to be the almost colourless and insipid liquid which is, I believe, called Jew's oil. There should be a taste of olive in it, but not so strong as to be disagreeable. It is a *quasi-nutty* flavour which it should have, and the colour should be golden.

The artistic salad maker could not be too particular in the choice of the vinegar to be used in his preparations. The British vinegar of commerce may be all very well for cooking purposes, pickling, &c.; but, for salads, vinegar made from wine should be used, and it should be clarified, so as to be almost as clear as water. The stronger the vinegar is, the better. At some first-class Italian warehouses good French vinegar is procurable for the asking; but it may not be out of place here if I describe the process by which a constant supply of wine vinegar, after the Gallic fashion, can be obtained.—Get a small cask made of oak which has contained wine. Heat to boiling point half a gallon of the best French vinegar, pour it into the cask, and roll it about in all directions, after which half fill it with some good white wine. Place your cask by the side of the kitchen fire, or, if in summer, in the open air, in a place well exposed to the sun. At the end of a week or so, throw in another half-gallon of boiling vinegar, and nearly fill up the cask with white wine. Leave the bung partially open, and in six weeks you can begin to draw as good vinegar as can be wished for. If every time any vinegar is drawn it is replaced by an equal quantity of white wine, the supply will never fail; and if at the outset a certain quantity of brandy be put into the cask, the quality and strength of the vinegar will be improved thereby. Vinegar greatly improves by age, especially when a vinegar plant—or “mother,” as we call it—forms in the cask; but this can be insured by procuring a vinegar plant, and putting it into the cask. None but wooden taps should be used to a vinegar cask, and the bung-hole should be covered with a piece of muslin—or the bung-hole may be stopped up, and an air-hole made in the head of the cask, and covered with muslin—for, in spite of the proverb, flies will be caught by vinegar.

When the acidification is complete and the vinegar ready for use, the cask can be removed from the side of the fire or exposure to the sun; but it should be kept ever after in a warm and dry spot, never in a cellar. To clarify vinegar, a wineglassful of milks should be mixed with a bottle of vinegar; then make a cone or filter of filtering paper, which you place in a glass funnel; pour the mixture into this very carefully, and in due course the vinegar will come out as clear as can be desired. For purposes of salad-making and cooking generally, vinegar is flavoured in a variety of ways. This is done by putting some good strong vinegar into a wide-mouthed bottle, and adding to it any of the following: 1. A couple of handfuls of tarragon leaves, gathered the day before. 2. Twenty or thirty green capsicums, previously bruised. 3. Four or five pods of garlic, also bruised. 4. A cupful or more of colery seed, well bruised in a mortar. 5. The same quantity of cress seed, similarly treated. The above proportions are for one quart of vinegar. The bottle should be corked up and exposed to the sun, or kept in a very warm place, for two or three weeks, when the vinegar should be strained and filtered, and it is ready for use. By a similar process vinegar is flavoured with mint, horseradish, cucumber, &c. The following are more elaborate forms of aromatised vinegar.

TARRAGON VINEGAR.—Fill up a stone jar or wide-mouthed glass

bottle with as many tarragon leaves, not newly gathered, as it will contain without pressing them down. Add a small quantity of cloves, and the rind of two or three lemons. Fill up with vinegar, cork well, and expose to the sun for a fortnight at least. At the end of that time, strain the vinegar, squeezing it well out of the leaves, filter, twice if necessary, through paper, and bottle up for use.

FINES HERBES VINEGAR.—Take equal parts of tarragon, garden cress, chervil, and burnet (all gathered the day before), one green chili, a couple of pods of garlic. Fill your bottle or jar with this, without pressure; cover up with vinegar, and treat as the above.

Another form of the above is this: Equal parts of tarragon, burnet, and chives, one or two lemon rinds, a few cloves. Proceed as above. Some people add to this a handful of fresh elder flowers. It is better, in making these vinegars, not to make too much of them, but just enough to last the season.

Although plain English mustard is often used in making salads, French mustard is undoubtedly better. The *moutarde de Maille à l'estragon* or à la *ravigote* is the best to use. The following recipe is the homely Gallic form of mixing mustard, which produces not a bad imitation of that of the celebrated *Maille*. Take about one quart of brown mustard seed, and mix with it the following ingredients: parsley, chervil, tarragon, burnet, about a handful of each finely minced; some celery seed, cloves, mace, nutmeg, garlic, and salt in such proportions as taste may suggest. Put the whole in a basin, with enough vinegar just to cover the mixture. In twenty-four hours' time proceed to pound it in a mortar, or, better still, grind it on a stone as colours are ground. When thoroughly ground or pounded pass through a fine hair sieve; add enough vinegar to make the mustard of the proper consistency; make a poker red-hot and stir your mustard with it; repeat this mysterious operation once or twice, and proceed to fill up your pots or bottles, cork and seal them. The pepper and the salt used for salad-making should be in the finest powder. Every kind of sauce, such as Worcester, Harvey, anchovy, ketchup, soy, &c., is used in salads, but they are dangerous things in the hands of novices.

Eggs, either raw or hard-boiled, should nearly always enter into the composition of a salad-dressing. In the former case the yolks alone are used; in the latter the yolks are applied to the same purpose, and the whites are put into the salad, or on the top of it, either chopped up small or cut in rounds. In some cases, besides the yolks which go in the dressing, whole hard-boiled eggs, cut into quarters or rounds, are used in the ornamentation of the salad. As a general rule I may say that the proportion of the oil to the vinegar should be, supposing the latter to be of average strength, as two to one; but due regard must also be given to the mustard and strong sauces, such as Worcester, which may be used. A couple of yolks of egg, either raw or hard-boiled, will be enough for an ordinary salad. The proportions of the other ingredients are a matter of taste, which cannot be defined.

Lastly, the proportion of the dressing to the salad must be such that when the two have been thoroughly mixed together no dressing shall remain at the bottom of the bowl. This will invariably not be the case when there is too much dressing in proportion to the salad, and also when the salad has not been properly freed from water, when too much vinegar has been put into the dressing, and when the ingredients have not been properly and artistically mixed. Therefore will it always be an indication of failure. It takes from forty to fifty minutes to mix a salad *secundum artem*; and although it is better to eat it as soon as the dressing and the greenmeat have been “worked” together, still it will keep good for an hour or so; after that it will rapidly deteriorate.—*The G. C. in “Queen.”*

 POLISH MODE OF PRESERVING CUCUMBERS AND
PICKLING MUSHROOMS.

In Poland cucumbers are preserved on a large scale, and constitute part of the winter provisions of the inhabitants. The following is the mode in which they are prepared:—They are gathered before they are too large (when scarcely one-third of their full size), carefully washed, well wiped, and placed, uncut, in layers in large earthenware pots, or in barrels, according to the quantity to be prepared. Each layer receives a suitable proportion of salt, and is then covered with a layer of cherry leaves mixed with fennel and a few oak leaves. The addition of vine leaves, in proportions of about one-half, produces a very good effect. The last layer is similarly covered with leaves, after which, the vessel being quite full, water (river water if possible) is poured in so as to cover the cucumbers completely (this is absolutely necessary). In about ten or fifteen days the cucumbers thus pickled may be used; before which they should be carefully washed, and then they may either be employed as pickles with other dishes, or eaten by themselves. As they do not keep long after they are taken out of the brine, not more than

the quantity required at the time should be removed. I make preserves of this kind every year, and use only the green Gherkin cucumber for the purpose, as I find the white kind does not keep so well.

Pickled mushrooms are also very much in use in Poland. Several kinds are thus preserved, but principally the sort called Rydz's (perhaps *Agaricus deliciousus?*). This mushroom, which grows in sandy districts in Fir woods, is excellent when fresh, and equally good when pickled. It is very abundant in Poland. Care should be taken to salt the mushrooms immediately after they are gathered. They should then be placed in earthenware pots, heaping them up as much as possible. Brine is then poured into the vessel, and the mushrooms are kept constantly covered with the pickle by placing over each pot a small board with a weight on the top. Before using the mushrooms thus pickled, they should be washed for some time in clean cold water, or even allowed to soak for a few hours in order to remove the salt. They may then be used in salad, and form a very agreeable dish.—*L. Paskiewicz, in "Revue Horticole."*

GREAT GARDENS OF EUROPE.

KEW.

THE SUCCULENTS.

THE Succulent House, a fine span-roofed building, is two hundred feet long and thirty feet wide. The central bed is on a level with the walks, and a series of arches support the side shelves, which contain soil, covered with sand; a plan in all respects excellent, both for partially concealing the hot-water pipes and for the health of the plants. There is, moreover, a good depth of soil secured in this way for climbers. Though this arrangement for side shelves is not adopted in any of the other houses, I have no hesitation in saying that for all kinds of plants in pots it is the best I have yet seen, especially where climbers are employed for the decoration of the roof, it often being the case in small houses that the pipes run round the sides, making it difficult to plant there. Besides, the warmth excites them the most when they should be at rest. By the arrangement I allude to, as carried out at Kew, the plants are entirely under control, water being given or withheld at pleasure; and the surface affords a natural and good resting-place for plants in pots, much superior to stone, slate, or wood, which can never be kept in so regular a state as to moisture.

The contents of this house form one of the chief features of Kew. Here may be witnessed Nature in a grotesque and somewhat capricious mood, as well as sullen and fierce. Now a gigantic Cactus or Agave seems to say this spot of earth is mine; *Nemo me impune lacessit* says another; and then there are the deadly milk-yielding Euphorbias; all of which are wonders in their way to sight-seers. Entering from the north, are some large plants of these Euphorbias; *E. canariensis*, *neriifolia*, *abyssinica*, *Tirucallii*, and *grandidens*, indicate the large amount of variety which exists among the different members of this genus. They are natives of Africa, India, and Tropical America principally; but the genus is found all over the world. They are interesting as showing a gradual leaf development, which is nearly perfect in *E. neriifolia*, very rudimentary in *canariensis*, and absent altogether in *aphylla*.

Turning to the right we come upon the Opuntias (Prickly Pear, or Indian Fig), the large-growing species of which come from Mexico, but there are many dwarf kinds that come as far north as the Northern States. The Gibraltar Prickly Pears are produced by monocantha and elatior. Next is a group of tall Cereus, or Torch Thistles, many of which have fine flowers, but the majority of them open only in the night. The most distinct are *C. Jamacaru*, *peruviana*, *grandis*, and *glaucus*; natives of Tropical America. Among the climbing species, in spite of the reputation possessed by *C. grandiflora* for beauty and size of flower, *C. Macdonaldiae*, *triangularis*, and *rostratus* are superior. These in their native countries climb the stems of trees; they therefore stand more shade than other sorts.

On the side shelves are arranged the dwarfer-growing species, many of which have fine flowers, and make good plants for rockwork in summer. On opposite shelves are

quantities of *Echinocactus*, *Echinopsis*, *Mammillaria*, and *Pilocereus*, or "Old Man" Cactus. Though some of the species, as *Echinocactus Stainesii* and *electracanthus* attain a height of six from six to eight feet, the majority of the sorts here are of humble growth. They are mostly Mexican, though some of the *Echinopsis* and *Mammillaria* are found as far north as the Rocky Mountains, just below the snow line.

Though the Kew collection contains many large and striking plants, yet the number of species is much below that of some private collections. In the central bed are the African or true Aloes; Barbadoes Aloes being, anomalous as it may appear, also obtained from South African species. Many of these Aloes are noble plants, as, for example, *A. africana*, *arborescens*, *pluridens*, *ferox*, and *supralensis*. Those which furnish the Aloes of commerce are *A. socotrina*, *A. vulgaris* (*Barbadensis*, or Barbadoes Aloes). What are termed Cape Aloes are the produce of *A. africana*, *arborescens*, and others. In books on medicine, *A. spicata* is said to be the plant that yields the Cape Aloes, but this is not to be found at the Cape, and is the scarcest of all the species of Aloes.

On the shelves are many small species, some of which are beautifully marbled. Gasterias and Haworthias are subdivisions of the Aloe tribe. Many of the Gasterias are remarkable on account of their distichous growth and exceedingly handsome foliage. Haworthias are a stemless class, growing in rosettes. They are very variable in form, but peculiar, inasmuch as their flowers are all alike; all of them are South African. Of Haworthias and Gasterias the collection is complete.

Opposite these are the Agaves (American Aloes), a group of noble plants from Mexico and Chili, where the natives call them "Karatto," and extract from them an intoxicating drink called "pulk." This is obtained by tapping the plant when the flower stem has grown a few feet, which happens when the plants are from seven to nine years old. It is a common belief that these plants flower only once in a hundred years, which is true in a certain sense of one section, the candelabra form, inasmuch as they die when they have flowered. To this section belongs the common American Aloe; the other section, of which *A. filifera* is a type, has a spicate inflorescence. Plants belonging to this class push a new centre and grow again after flowering. Amongst them is the nearly allied genus *Fourcroya*. When they flower they form numbers of young plants in the axils of the flower stalks, like small onions. These grow, and thus perpetuate the species. It is mentioned in the guide to Kew that two plants of *Fourcroya gigantea*, which flowered in 1844, pushed up flower stalks at the rate of ten feet in twenty-four hours! They certainly do grow very fast. I have myself known them make one foot in that time, but never so much as ten. The Agave collection here is very incomplete, many of the more recent introductions not being represented. We come now to some noble specimens of *Dasyliorhiz* and *Beaucarnea*. *D. longifolium*, especially, with gracefully drooping foliage from eight to ten feet long, is a noble plant for a cool conservatory, as is also *Beaucarnea glauca*, a plant peculiar on account of the large corrugated tuber to be found at its base. They are natives of Mexico, where they grow at high elevations, and will stand several degrees of frost with impunity. Mixed with these are some of the coarse Australian grasses, as *Arundo conspicua*, *Xerotes longifolia*, and the *Xanthorrhoea*; also the *Dianellas*, Liliaceous plants with beautiful blue flowers and berries. On the side shelf here is a grand collection of the arborescent *sempervivums* from the Canary Islands.

Passing the south door, we come to the Crassulas, Cotyledons, and Kleinias, South African plants. Among them are many useful subjects for ornamenting outdoor rockwork in summer. Next come the Echeverias, the Mexican type of Crassulaceae. Though several of the genera in this house are not so well represented as they might be, still this is one of the most interesting houses in the garden, and it is also one of the best arranged for public inspection, the whole of the plants being easily seen from the walks, a point of much importance in a public garden.

In the north end of the new range of houses at Kew will be found the collection of Mesembryanthemums, which is

very extensive, containing no fewer than 212 species. They are natives of the Cape of Good Hope, where they grow on rocks, into the fissures of which they get their roots, a circumstance which enables them to stand severe droughts. Some found in Australia are evidently Cape species that have naturalized themselves there. *M. spectabile*, *polyanthum*, *retroflexum*, *roseum*, *formosum*, *blandum*, and *aureum*, together with several allied species, are all beautiful, and have a grand effect on rockwork. *M. felinum*, *tigrinum*, and *lupinum* are useful as margins to beds. The genus *Mesembryanthemum* may be said to be one of the most interesting and variable among Succulents, both on account of form of foliage and regularity in regard to the periods of opening and closing of the flowers.

The following summary will show what are at Kew, in the way of species belonging to certain genera, compared with what have been introduced into this country:—

<i>Cereus</i>	at Kew	...	87	Introduced	...	148
<i>Mammillaria</i>	do.	...	77	do.	...	174
<i>Echinocactus</i>	do.	...	44	do.	...	116
<i>Echinopsis</i>	do.	...	22	do.	...	22
<i>Opuntia</i>	do.	...	62	do.	...	91
<i>Agave</i>	do.	...	46	do.	...	140

Although there is room for improvement as regards the collection, this singular and wide-spread type of vegetation is nevertheless nobly represented at Kew, and the large Succulent House, is, on the whole, as satisfactory from every point of view as any similar structure yet erected.

J. CROUCHER.

(To be continued.)

NOTES.

Ipecacuanha Plants.—Those in the Neilgherries are reported to be flourishing. Two have blossomed, but have yielded no seed. Twelve plants in good condition were received at the Calcutta Botanic Gardens from England in August.

Daffodils.—In our report of the last meeting of the Royal Horticultural Society we accidentally omitted to allude to the fine collection of Daffodils shown therewith by Mr. Peter Barr, in whose experimental ground at Tooting there is now the most interesting collection of Daffodils we remember to have seen. Mr. Barr deserves great credit for the thorough and enthusiastic way he has taken up this fine family, which, considering its immense variety, its thorough hardiness, and its flourishing on any soil, is second to none in its importance.

Caution to Eaters of Water-cress.—A correspondent of a Bristol contemporary writes:—"On Saturday last a man passed my house crying 'fine fresh water-cresses.' One of my boys ran after him and bought a pennyworth. Fortunately, before being placed on the table my attention was called to them, and I found that three-fourths of the lot were composed of water cowbane (*Cicuta virosa*), one of the most virulent of English vegetable poisons."

Australian Mahogany.—The Jarrah Jarrah, or western Australian mahogany, is becoming famous, and its value has been greatly enhanced by recent Government tests, showing that the durability of the wood is dependent not so much on its density as on a certain astringent vegetable acid, which appears to be so peculiarly disagreeable and even poisonous to insects that they avoid the timber.

Trees bad Dentists.—An economical Iowan, who had the tooth-ache, determined to remove his tooth in the Indian fashion. Accordingly he bent down a sapling in the woods, lay down himself, and attached a stout cord to his tooth and the sapling. Then he touched the spring, and the next thing he knew was that he had jumped over a grove of about forty small trees, and was trying to get out of a small pond into which he happened to alight.

Victoria Park Extension.—The Victoria Park Preservation Society have abandoned their intention to attempt the purchase of the nine or ten acres of building land which skirts Victoria Park, insurmountable difficulties having presented themselves; and they have decided to confine their attention to that portion consisting of about five acres, which is situated opposite the fountain erected by the Baroness Burdett-Coutts. The eastern portion of this strip of ground immediately adjoins Hackney Common, being only separated by a roadway. It has, therefore, been suggested that Hackney Common should be joined to Victoria Park, and the two spaces made into one large recreation-ground under one management. The secretaries of the Victoria Park Preservation Society have therefore again addressed Lady Burdett-Coutts on the subject, with the view of inducing her to purchase the small strip of land referred to.

Gardening in Elementary Schools.—A very important development in the organization of the teaching of agriculture and horticulture is to take place in France. It has just been decided that these studies, so useful for the populations of rural districts, will have a piece of ground devoted to them, in the vicinity of each school, which will be under the superintendence of the teachers. In this, the best systems of garden cultivation will be shown, and in particular those which relate to fruit culture and arboriculture. A circular is soon to be addressed to the communes, asking their active co-operation in this matter.

Parrots as Fruit Eaters.—Flocks of green parrots, says the *Kyneton Guardian*, are committing sad havoc in the fruit gardens and orchards around Kyneton. Nothing comes amiss to them so long as it is ripe. We know of one instance where gooseberries, from which it was calculated that three hundredweight of jam would be made, have been entirely destroyed. Plums and other descriptions of stone fruit are greedily devoured, and as soon as an apple or pear ripens it is seized upon by these ravenous fruit eaters. Quite recently thirty-eight parrots were shot on two or three trees, the birds particularly affecting a very choice jargonelle pear now ripening.

Presentation to the late Curator of the Liverpool Botanic Gardens.—On the occasion of Mr. Tyerman retiring from the curatorship of these gardens, which he has lately done, a number of his botanical colleagues determined to present him with a small expression of their personal esteem. A handsome silver centre piece, composed of the main stem of a vine, supporting a cut glass dish, with three branches, decorated with vine leaves and grapes beneath, was purchased by means of a liberal subscription list, and has been presented to Mr. Tyerman. It bears the following inscription:—"Presented to John S. Tyerman, Esq., on his resignation of the curatorship of the Botanic Gardens, Liverpool, by a few friends, to mark their high personal esteem, and in recognition of his scientific attainments, 1872."

A New Idea in Planting.—A great discoverer, whose name cannot be long concealed from a grateful world, has invented a plan of replanting the hair where it is lost. As plants grow so does the hair; it is rooted, and thrives like a vegetable. The operation of restoring hair is very simple; put healthy hairs into the eyes of needles and draw the needles through the upper skin, the epidermis; being drawn through, the hairs are left in the skin, as a thread, may be left in any material by a stitcher. The roots, which have been extracted with their bulbs complete, are brought under the epidermis. The surface so operated on is protected at first by a linen band, but the hairs soon take root, grow, and flourish. It is not stated whether having the skin punctured in this way is disagreeable, and how often it is fatal. If it is a success, the plan has many advantages: one can have any colour of hair he may select, and he can plant a variety of colours, and thus make his appearance striking and beautiful.—*American Paper*.

Botanical Ponies.—According to the *North Wales Chronicle* the quadrupeds in the neighbourhood of Snowdon are more highly educated than lots of bipeds we know. It says that an hotel-keeper in that district—

"Furnishes guides and ponies, who are perfectly acquainted with all the rare plants in the locality."

A pony that thoroughly understands botany is indeed a highly-trained steed, before which the gifted of the circus must bow.—*Fun.*

THE SEASON.

THE East wind blows cold, and Jack Frost lays his hold

On noses and fingers and toes;

In dull leaden grey scowls the sky all day,

And at last weeps its sulks out in snows.

And the pretty pink blossoms of almond and peach,

And the apricot's petals so pale,

Of cruel Jack Frost vainly mercy beseech,

Or of cruel Easterly gale!

And they piteously cry with a shudder and sigh,

As they shrivel and shrink on the wall,

"Poor fools to be lured by a blink of blue sky,

But to flush, and to fade, and to fall!"

—*Punch.*

FLOWERS OF FASHION.

Lady.—"And why did you leave your last situation?"

Coachman.—"Well, ma'am, me and her ladyship 'ad a difference about a bokay. We was going to a Drawing-Room, and her ladyship wanted to put me off with a bokay made up in the 'ousekeeper's room! Well, I couldn't stand that, so I went and ordered a bokay at Covent Garden; and, would you believe it, ma'am, me and her ladyship 'ad a difference about the payment? so I give warning!"—*Punch.*

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

PRIVATE GARDENS.

Indoor Plant Department.—By way of compensation for the winter weather which we are now experiencing out of doors, conservatories everywhere are being kept as attractive as possible. Cyclamens, those charming early flowers with which everybody's pleased, are now getting past their best; but, owing to the forwardness of the season, there is no lack of flowering plants to fill their place. Young and tender shoots, as well as blossoms, are carefully guarded from frosty winds. Camellias, Acacias, Rhododendrons, and other shrubs, with the exception of such as are in flower, are syringed every morning, the afternoon applications being for the present discontinued on account of the coldness of the weather. Camellias and Azaleas that have been headed back are placed in vineeries, or other moist, warm houses, where they are breaking admirably; they are frequently syringed overhead, but water at the root is given but sparingly. Small-growing plants of those are not allowed to suffer from being pot-bound. Among Caleolarias, the most forward receive a little weak manure-water occasionally, which strengthens the flower-spikes, and improves the quality of the bloom. Balsams, Cockscombs, and similar plants, are regularly shifted, so as to obviate anything in the way of a check, and gentle bottom heat and plenty of air promote compact and stocky growth. Fuchsias, Alyssums, and Plumbago capensis are pruned back, potted, and started, to succeed those previously placed under growing circumstances. Hyacinths, Tulips, and other bulbous plants done flowering are being placed in cold frames, and kept rather dry. Zonal Pelargoniums intended for blooming indoors are shifted into two-sized pots larger than those in which they were wintered. Fancy and show Pelargoniums are neatly staked, and kept near the glass; air is freely admitted, except when the weather is frosty. Stoves are allowed a little extra heat and moisture, and care is taken to guard against undue ventilation whilst the weather continues so cold. Climbers, such as Allamandas, Bignonias, Clerodendrons, Dipladenias, Passifloras, Stephanotis, and Thunbergias, are now in full growth, and receive strict attention as to thinning, stopping, and tying. Russellias, old-fashioned plants not half so often met with as they should be, are being potted in light rich mould, and staked, allowing them to retain, to some extent, their natural pendent habit. Ixoras are pruned into shape, and are growing fast. Rivas, well-known little berry-bearing plants, are pruned rather closely back, and are starting freely—others are raised from seed. Eschynanthus, which are reported, are, for the most part, grown in baskets. Gardenias receive a liberal supply of water, both at the root and overhead. The prunings of Cissuses, which are cut back, are being used for purposes of propagation. Begonias, charming winter and early spring-flowering stove plants, are now everywhere in great beauty. The old-fashioned red and white Vincas are cut back to good eyes, potted, and started. Orchids, especially those in flower, and such as are rapidly advancing in growth, receive a little shade during the brightest part of the day; a steady, moist, and warm temperature is maintained, and, to such as are in active growth, water is freely given.

Pits and Frames.—The propagation of bedding-plants is being pushed forward vigorously, cutting the shoots off at a joint, from which, in a short time, two other shoots push forth. There is thus no scarcity of cuttings, which as soon as rooted are potted off singly, and kept until established in warm quarters. As soon as they begin to emit fresh roots, they are transferred to a colder frame, where they are gradually hardened off. This treatment does not, however, do for Alternantheras and similar plants; for unless these are kept in heat, and well established before being placed in cold frames, which should not be done till the first of May, they will not make good plants. Stocks, Astrors, and Marigolds are being sown in gentle heat, the seeds being shaded to prevent undue evaporation. Sweet Peas, favourites with everybody, are being sown in pots and boxes for filling up vacant spaces that may occur amongst those sown outside. Auriculas in frames are protected with mats, giving them free exposure during fine weather; their foliage is kept as dry as possible. Dahlias are being propagated in heat. Carnations and Pinks for flowering in pots are repotted, and those not required for pot culture are planted out, or are set for the present in some sheltered place and protected with mats. Heartsease are repotted and placed outside, protection being afforded them at night by means of hoops and mats.

Flower Garden and Shrubbery.—Notwithstanding the inclemency of the weather, well-managed flower gardens present just now a neat and attractive appearance. Among the more striking plants now to be seen in flower in them are Daisies, Heartsease of different sorts, Arabis, Violets, Squills, Anemones, and Daffodils.

The Golden Feverfew is also very pretty. Annuals required for early flowering, such as Mignonette, Nemophila, Saponaria, Collomia, and Candytufts, &c., are being sown, and various hardy annuals, such as the Nemophilas and Candytufts, from late autumn sowings are being transplanted. Sweet Peas, sown where required, are sharply guarded from mice and wood pigeons. Auriculas, Pansies, Carnations, Pinks, and Picotees are being bedded out. Sweet Williams and Wallflowers from seed are also transplanted. Gladioli, if not grown in pots, are planted out where they are to bloom, placing a little sand around the bulbs; any of them in previous plantings likely to be pushing, have some litter laid over them to preserve them from frost. Hollyhocks are being transplanted to their blooming positions, using for them a rich compost. Peonies, the young shoots of which are beginning to grow, are protected by having mats or straw laid over them at night. Rose pruning, in most cases, is now finished. Flower beds not planted with spring flowers, are pointed over and neatly raked. Edgings to beds and borders, such as Ceratostylis, Stachys, variegated Polyceratiums, Arabis, Ivies, and grass continue to be made. Lawns in which grass is deficient and moss prevalent, are top-dressed with rich, finely-sifted soil, raking off at the same time any rough material that may be disfiguring their appearance. They are then rolled. Conifers which seem inclined to produce contending leaders, have the worst of them rubbed off, leaving only the strongest and most promising. Evergreen shrubs are pruned into shape, using only the knife in the operation, except in the case of strong limbs, when the saw is employed.

Indoor Fruit Department.—To Pines a steady temperature is maintained, and they are never allowed to suffer from want of water. Those colouring fruit are kept rather dry, as are also those in flower. Suckers potted are plunged in tan beds. Succession plants are in some cases shifted into their fruiting pots, and plunged in brisk heat. Vines are thinned as they require it, at the same time pinching and tying the young shoots. Borders heated artificially are frequently examined so as to prevent their ever becoming too dry, and atmospheric humidity is maintained by frequently syringing the floor, walls, and stages; but it is not advisable to syringe vines after they show fruit, except for the purpose of keeping down red spider. Peaches and Nectarines while stoning are kept at about 60° at night. More fruit than enough for a crop is allowed to remain on the trees until after the stoning period has been passed, when they are thinned to the required distances apart. No more young wood is left than is absolutely necessary for next year's crop. Tying and thinning the shoots are attended to, and the syringe is used freely amongst the foliage to prevent red spider. Figs have plenty of moisture both at the root and overhead; attention is also paid to pinching the shoots at the fourth or fifth joint. Where Cucumbers have been grown throughout the winter and have become exhausted, the borders are partially renewed and young plants put in between the old ones. As soon as roots appear outside the soil, they are top-dressed with rich mould, and well watered both at the root and overhead. Melons are thinned and tied as they advance; they are not allowed to set fruit until the plants have attained sufficient strength to bear it, and all superfluous blooms and growths are removed. Vegetable Marrows and Gourds are being sown, and plants from some of the earlier sowings are potted off. Strawberries are now in full bearing, those ripening being kept rather dry and near the glass; successive plants are being introduced. Mushroom beds are at present kept moist enough by the straw with which they are covered, and attention is paid to prevent the attacks of mice, slugs, and earwigs. Fresh beds are being spawned. Of Chicory, Dandelions, and Endive a supply is taken into the mushroom-house to blanch and force. Mustard and Cress are still sown indoors. Nasturtiums for salading are sown in gentle heat for transplantation. Onions raised in heat are freely exposed whenever the weather is at all favourable. Celery is pricked out on a compost consisting of well-decomposed manure two parts and light soil one part. This is placed about six inches deep on a hard bottom covered by a frame and sashes, over which are placed at night straw or mats. Capsicums are shifted and kept near the glass. Egg plants are trained to one stem, pinched, and well syringed, and kept near the light. Endive is sown in brisk heat. Kidney Beans are sown for succession. Potatoes requiring earthing up are well watered, after which, when the surface is dry, the earth is drawn to them.

Outdoor Fruit and Kitchen Garden Departments.—The sudden and winterly change which the weather has assumed has greatly altered the character of operations in this department at present. Fruit trees seem to have suffered considerably, especially the earlier kinds of Pears and Plums, whose blossoms had opened. The snowstorm which occurred on the 21st instant blackened those on standards at the base of the pistil; those on walls, though in some cases unprotected, are not so badly injured. Grafting for

the present is postponed, the frost causing the clay to expand and fall off. In the kitchen garden the transplanting of vegetables and sowing of seeds are also deferred till brighter days make their appearance, as it is considered nothing is gained by sowing seeds in cold wet soils. Crops that must be forwarded had better be sown under cover, and transferred, after having been properly hardened, to the open quarters, when the weather shall have become more favourable.

NURSERIES.

Indoor Department.—Propagating soft-wooded plants still occupies the chief attention in this department. Coleus, especially the newer kinds, are being largely increased, potted, and grown on. *Amarantus calycinolus* appears to come freely from seeds; the young plants from these are pricked off into pans as soon as fit to handle. *Chirnia frutescens* is being sown on rough peat in pans, covered with glass, and set in gentle heat. Plants of *Eucalyptus globulus* from seed are being potted off singly. *Mesembryanthemum linguaforme* is found to come true from seed, from which abundance of plants may be raised in a shorter time than from cuttings. *Musa Ensete* is also raised from seed, one of which is put into a small pot with a little silver sand around it, and the pots are plunged in gentle bottom heat. *Daturas* are propagated from portions of the old wood, each piece containing one or more eyes being placed in silver sand in heat. *Cestrum aurantiacum* is obtained from cuttings, as are also *Bouvardias*, which are easier to strike now than in autumn. *Cassias*, *Cytisus*, *Prunus*, and *Melianthus*, are likewise being raised from cuttings in heat, and those rooted are potted off singly. Seeds of hybridized Begonias are being sown in pans of light soil plunged in bottom heat. Variegated Maize is also sown thinly in pans, in heat. Ornamental grasses are sown in pots, and kept in cool pits or frames. *Primulas* are also being sown and kept in cold frames. *Tacsonias* raised from seed and now well established, are placed in cold frames, protected by extra coverings at night and during severe weather. *Hibiscus*, *Coronillas*, *Matricarias*, *Sedums*, *Solanums*, Vines, &c., that have been raised from seeds and from cuttings, and now pretty well established, are transferred to cold frames. *Cyclamens*, from December sowings, are being potted off singly into small sixty-sized pots, and kept in a gentle heat. Young *Camellias* are being pruned into shape, placed in a higher temperature, and frequently syringed. Grafting of young Conifers, Iries, Hollies, Roses, and Rhododendrons is still proceeded with, keeping them closely shaded, and in gentle heat.

Outdoor Department.—Herbaceous plants have not been injured apparently by frost, but where the soil is heavy they seem to have suffered a little from damp. Such as are in pots are examined, divided, and re-potted, and kept in frames, or placed along the foot of walls or hedges, protecting them during severe weather by means of mats supported on stakes. *Nymphaeas* and other water plants are being re-potted and placed in tanks out of doors, and some of them are beginning to grow freely. Preparation is being made for seed beds of hardy conifers, such as Scotch firs, larch, &c.; those in last year's seed beds are being loosened with a fork and transplanted in lines eight or ten inches apart. Two and three year old plants are also transplanted, the strongest being selected from amongst the others, and according to their strength the distances apart are determined. Three and four year old plants of these are those most in demand for permanent plantations. Seeds of deciduous trees are now being sown. All trees and shrubs remaining after the winter sales are now being transplanted and re-arranged.

MARKET GARDENS.

HERE the weather has also checked ordinary operations to some extent. Besides some injury done to fruit trees, little else however, has suffered, except perhaps the later planted Lettuces, some of which are a little browned. In many cases they are much eaten by slugs, which shows the necessity of sprinkling a little soot or lime over the ground. The crowns are, however, safe. Radishes of first sowings are now pretty strong; the younger ones are still covered over with litter during the night and in severe weather. Litter is also placed over Rhubarb by way of protection. Spinach, Onions, and a few other crops coming up amongst bushes and under trees, are apparently unharmed. Over Gooseberry bushes, and amongst some of the other crops, is sprinkled a dusting of lime, to act as a preventive of insects. Beds are being made up for Cucumbers, by taking out a trench about $2\frac{1}{2}$ feet deep, and filling it up with hot dung, over which is placed a few inches of soil. On this the frames are placed, and along the middle is put a ridge of prepared soil on which the Cucumbers are planted. Beds are also in course of construction for Vegetable Marrows, but to these not quite so great a depth of dung is given. Seeds of these are also being sown on a

little heat, and some of the further advanced are nearly ready for planting. Tomatoes are potted and kept in frames covered over at night with litter. In the open ground, besides collecting vegetables daily for market, manure is being carted on to vacant ground, which is also being dug.

HOW PLANTS ARE FERTILIZED.

A LECTURE on this subject was delivered at the London Institution, on March 21st, by Mr. Alfred W. Bennett, F.L.S. The lecturer commenced by stating that there are two modes in which plants may be propagated: the vegetative, in which a portion of the mother plant, containing a leaf-bud, is placed under suitable conditions to make it develop into an individual in every respect resembling the mother plant; and the reproductive, by the agency of seeds. The different organs of a perfect flower were then described; the non-essential whorls constituting the calyx and corolla, and the essential whorls formed of the stamens and pistil. The difference was then pointed out between the unfertilized ovule contained within the ovary, and the perfect seed containing a distinct embryo; the form of the embryo in different seeds being illustrated by drawings. After a more minute description of the structure of the ovule, and of the stamen and pollen grain, a detailed account was then given of the process of emission of pollen tubes, which results in the fertilization of the ovule. The lecturer then proceeded to explain that although a perfect flower contains both stamens and pistil, the male and female organs, yet this by no means necessarily occurs, the sexes being sometimes separated. When this is the case, the male and female flowers are sometimes similar in appearance, as in the cucumber tribe; sometimes entirely different, as in the hazel. When the sexes are thus separated, some foreign agent, as the wind or insects, is obviously necessary to insure fertilization; but even in hermaphrodite flowers, the researches of Darwin and others have shown that self-fertilization is the exception rather than the rule. In many plants, self-fertilization is prevented by the fact that the anthers and the stigmatic surface of the pistil are not fully developed at the same time; but either the anthers have discharged their pollen and dropped before the stigma is ready to receive it, or the reverse. In other plants we find special contrivances for cross-fertilization by insect agency, the two which were specially dwelt upon being the cases of *Salvia* and *Orchidaceous* plants. The arrangement was described at length by which the pollinia of Orchids are removed by the proboscides of moths and butterflies, and contrived for the fertilization of the next plant visited. It was mentioned in this connection that the limit of latitude which annual plants attain in their native state is determined, not so much by the temperature which is required for their growth, as by the presence or absence of the insects which are necessary to their fertilization. The abnormal phenomena of parthenogenesis were referred to, and specimens shown of the *Zanthoxylon*, described by Mr. Hanbury, in the *Journal of the Linnean Society*, which bears only female flowers, and yet produces perfect seeds, one in five of which are found to germinate. In conclusion, the lecturer alluded to the practical importance of the subject, especially with reference to the "setting" of fruit, the failure of which in cold weather he believed to be due not so much to the actual injury to the flowers as to the destruction of the fertilizing insects. The lecture was copiously illustrated by diagrams as well as by living specimens.

ANSWERS TO CORRESPONDENTS.

NORTON (We shall shortly publish an article on the subject.)—E. F. W. (We have no personal experience of the working of the stove you name.)—M. (Next week.)—O. G. W. (We know nothing of the material mentioned in *Public Opinion*. Thin muslin bags will preserve grapes from wasps.)—W. J. C. (Ammoniacal liquor is a powerful fertilizer, but it needs diluting with at least six times its bulk of water. In this state it may be applied to most kinds of vegetables with advantage.)

NOTICE.—Country booksellers having reported some of the earlier numbers of "The Garden" to be out of print, we beg to state that every page has been stereotyped, and consequently "The Garden" can never run out of print.

Readers who may find it difficult to procure THE GARDEN regularly through the newsmen, may have the numbers sent direct from the office, at 19s. 6d. per annum 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsmen, at the railway book-stalls, and from the office.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

THE HISTORY OF ROSE DEVONIENSIS.

I HAVE often intended to write the history of this well-known rose, and "D. T. F.'s" version of it in your columns, which is the only one I have seen, induces me to offer mine.

Mr. G. Forster, who was a retired clerk of the Devonport Dock-yard, and with whom I had a rather intimate horticultural acquaintanceship, had quite a passion for growing seedlings of all kinds, his chief hobbies being Dahlias and Pelargoniums. As all, or very nearly all, the care of rather large gardens and conservatories devolved upon him and his brother, "high" horticulture was not carried out, and I have seen fully one thousand seedling Pelargoniums spindling up in sixty-sized pots, ranged out against a wall, and afterwards running up on a single hard-wooded stem to three feet or more before they bloomed. The consequence of this hard treatment was, that whilst, undoubtedly, many good flowers were thrown away, those that turned out well generally proved gems.

One day I chanced to meet Mr. Forster near his house, when, in his usual quiet, dry manner, he said, "The next time you are at leisure to come to my garden, I hope to have something to show you." To this I replied, that if the something was then to be seen, I would go at once. Thinking that he referred to a Pelargonium or a Cineraria, I expected to see nothing until we reached the greenhouses, when, stopping at a frame, he lifted the light, from which rushed a gush of scent, and there was Devonensis, a small plant with a solitary bloom, but which measured 5½ inches in diameter, and I am not quite sure whether it was not a quarter of an inch more.

And here I may say of my old friend, that he was a man of considerable native intellect and force of character, and would probably have made his mark in the world if he had had the opportunity. Like most thoughtful men, he was very reserved, though in that respect he improved considerably on acquaintance; but he had the organ of "secretiveness" developed to an extent, which even all his natural amiability failed to counteract, and, kindly as he always received me, he never offered me a cutting of a plant, or even a specimen bloom. Knowing his ways so well, I was somewhat surprised at his exhibiting the infant prodigy, and felt somewhat vain in the thought that I had succeeded in getting into his confidence. But I was undeceived ere long, for I found out afterwards that the seedling was then two years old, had been propagated largely during the preceding summer on all sorts of stocks, and as they were near flowering, and the secret could not be kept much longer, I had been let into it.

All my attempts to urge him to advertise the plant appearing to be useless, I thought I would try the effect of sending a customer to him, and accordingly, when next in Exeter, I spoke to the late Mr. Pince on the subject, who said carelessly that what were swans in raisers' hands proved often to be geese in his. He so far, however, yielded to my representations as to say that he was going to send some plants to the autumn Horticultural Show at Plymouth, and he would tell his foreman to inquire about the matter. Shortly after the show just mentioned I called on Mr. Forster, when he told me that he had sold the plant, and that Mr. Pince's foreman had gone off with a faggot of boughs to bud from at once; and then for the first time did I learn how long the stock had been in the raiser's possession. And here I may observe that there is a slight difference between "D. T. F.'s" account and mine, for my version is that Mr. Forster got only £20, and when (as I believe) he told me so, I remember exclaiming that I would have either given it away or else had £100. I may also add, on Mr. Forster's authority, that Mr. Pince did not send out the rose till he had a thousand one guinea orders for it.

I shall now proceed to give you the early history of the plant, which is a somewhat curious one, and I will do so as nearly as I can in Mr. Forster's own words:—

"The mother plant was a Smith's Noisette, which I was chiefly induced to buy because it had a pod of seed on it nearly ripe. I did not expect much from it, as I had heard that French rose-wors

had discarded it as a bad breeder, but I thought I would give it a trial. When I sowed the seed I did not think it would germinate the first year, and thought very little about it. But one day I observed traces of a slug over the mould, and suspecting that some mischief was abroad, I got a magnifying glass, and found that the seeds had germinated a year sooner than I had anticipated, and that all of them had been eaten off but two. Those two I saved; no others came up, and that is the history of Devonensis."

I said at the outset that Mr. Forster's mode of gardening was rather rough, and I may also add that he did not grow seedlings for the market (though many of them ultimately found their way there), but purely for the pleasure of rearing novelties, which he was always reluctant to part with. To these two causes I attribute the fact which will, I suspect, be new to most of your readers, that there are two kinds of Devonensis. Both of the surviving plants turned out gems, and having a general family likeness, have always passed as one. This to my mind accounts for the different characters given of the plant, some calling it very delicate, others reasonably hardy of its kind, whilst occasionally I have heard the difference in the growth or bloom attributed to soil or aspect.

The two plants may be thus described, if my memory serves me rightly:—

No. 1, which I call the Devonensis, it being the one that I first saw, is the larger flower of the two, and is of a pale uniform colour throughout, whilst the petals have a much thicker substance, and the growth of the plant is weaker than that of the other.

No. 2 is harder, stronger growing, almost if not quite a climber; has somewhat smaller but more compact flowers, the centres of which are of a darker tint than the outer petals, being almost of a salmon colour, and the petals are slighter in substance.

Between the two there is not much to choose, but I should recommend the former for the greenhouse, and the latter for the open wall, though I have seen No. 1 answer very well on a briar stock under the deep sheltering eaves of a low wall. I think it would be worth some nurseryman's while to procure the two sorts and keep them distinct.

I may add that the foliage of No. 1 is larger in its individual leaves than No. 2, but has not so many on a leaf stalk. The test, however, between the two kinds is the presence or absence of the salmon-tinted centre.

S. P.

NOTES OF THE WEEK.

— A VAST amount of damage has been caused to the early potato crop in Jersey by reason of frosts suddenly succeeding fine open weather. The plants had grown strong and healthy, and gave promise of an early and abundant crop. The damage is estimated at many thousands of pounds.

— The directors of the Alexandra Palace Company have appointed Mr. Gilbert R. Redgrave to be their manager. The railway into the building is nearly completed, and the works are in a very forward state. The palace and park, comprising nearly two hundred acres of land, will, it is said, very shortly be thrown open to the public.

— A MUSHROOM, measuring four and a half inches across, was found last week on the open downs, at Wiltshire Corner, on the Earl of Craven's estate at Ashdown. It is an unusual occurrence to find such a fine mushroom so early in the season, adding as it does, another testimony to the forward state of vegetation previous to the recent severe cold.—*Newbury News*.

— WE have all heard of poisoned sugar plums, but the German newspapers are now discussing the various cases of poisoning by Vanilla ices, which have occurred of late years in Paris, Altona, Munich, Vienna, and other places. According to one doctor the poison is in the Vanilla, and it is produced by the use of cashew-nut oil to balm the Vanilla pods.—*Graphic*.

— It is proposed to form a new road from Victoria Park to the East London Museum on Bethnal Green. The road would run from the south side of the museum in a north-easterly direction to a junction with the Approach Road at its south-western end, and thus a broad thoroughfare would extend from the museum to the gates of the park.

— THE urgent representations made respecting the foul condition of the bathing lake in Victoria Park have at length influenced the Office of Works to take remedial measures. With this object an artesian well is now being sunk near the lake, which will not only be ample enough for the supply of water for bathing purposes, but will also suffice for the other requirements of the park. As the foul state of the lake was due to the extremely meagre supply of water, it is anticipated that the steps which are being taken, together with

an efficient dredging of the bed, will restore the lake to a satisfactory condition.

— DR. McNAB, Professor of Botany and Geology at the Royal Agricultural College, Cirencester, son of Mr. James McNab, of the Royal Botanic Garden, Edinburgh, has received the appointment of Professor of Botany to the Royal College of Science and Art, Dublin.

— MR. ALFRED SMEE, F.R.S., has in the press a volume entitled "My Garden," in which he gives a description of his garden in Surrey, and details the results of his experience in the culture of flowers and fruit; of these nearly seven hundred species and genera are described. The volume also treats generally of the natural history, geology, and antiquities of the neighbourhood.

— M. ALPHAND has retired from the superintendence of the Paris improvements. Appointed to his post in 1854, after a very successful career of engineering at Bordeaux, M. Alphand remained in office amid all prefectoral changes, and was the virtual author of the rapid, costly, and beautiful transformation which will stand to the credit of the Second Empire so long as Parisians love bright streets, showy gardens, and fresh air.

WHEN the Queen of Denmark paid a visit to the Pope the other day, she asked him, as a souvenir of her visit, for a flower from his own gardens, the only thing one could possibly ask from so poor a man as Pius IX. But Pius IX., perhaps to throw discredit on the assertion of the Archbishop of Paris that his Holiness possesses not so much as a stone on which to lay his head, sent the Queen of Denmark a most beautiful bouquet in a rich Sevres vase.

— SINCE the great snow blockade occurred on the Union Pacific Railroad, there appears to have been an increased interest awakened in regard to planting trees near the railroad lines that cross the great prairies. High board fences will never answer as obstructions to snow; in fact, they usually cause high drifts, and do more harm than good. What is wanted is something that will partially check the wind and break its full force. A wide belt of compact-growing evergreen trees and shrubs is the one thing required.

— THE game preservers in Kent and Surrey have determined for the future to exclude from the coverts, &c., a class of men who migrate from London during spring into the country districts under the pretence of collecting wild flower roots, moss, &c., but who are virtually in search of eggs of pheasants and partridges for sale. A general order has been given to gamekeepers to drive off all trespassers found in the woods, whether actually gathering or pretending to gather wild flowers, as the only means of checking the traffic in game eggs.

— A CORRESPONDENT of the *Times* says:—In the Dublin Botanic Gardens on the 24th of February last I took down the names of seventy-five different sorts of flowers in bloom. I have since that time seen cottagers' gardens in different parts of this country smiling with the bloom of beautiful, yet common hardy plants. To day (March 28th) passing along the Thames Embankment, and by the garden in the Westminster Palace Yard, and the neighbouring enclosure, I notice not one blooming plant. It may be that those who have control will be able and willing to arrange to have a different appearance by next March, and thereby gladden the hearts of many, to whom flowers in spring are even more than at other times pleasing.

The Professorship of Botany at Strasburg.—The new Imperial régime in Alsace has secured to the University of Strasburg an efficient Professor of Botany in the person of Count Solms-Laubach, the first Prussian *Kavalier* who has condescended to prefer the pursuit of science, with the view of making a living by it, to a career in the army.

Sea Pine Plantations in France.—We learn that extensive plantations of the Sea Pine (*Pinus maritima*) have been made on the peaty plains and sandy downs of the coast of Bordeaux; this has been effected for the purpose of supplying railway sleepers, pit-props for mines, smaller wood for fencing and firing, as well as for the resin furnished by these trees, all articles of value and in considerable demand.

Erection of the Kibble Conservatory in the Glasgow Botanic Garden.—This conservatory, we understand, is to be moved from Coulport, and put up in the east end of this garden, where for the future it is to be called "The Kibble Crystal Art Palace and Conservatory." At Coulport Mr. Kibble has a staff of workmen engaged in taking down the conservatory. The contents of the large dome are now being displaced, after which the removal of the structure itself will be proceeded with. When this has been accomplished, it is intended to go on at the Botanic Gardens with the erection of the two refreshment-rooms attached to the conserva-

tory, in which the statuary and plants will at first be placed after their removal from Coulport. Then the large dome will be raised, and afterwards the smaller dome. Both will have a height of about forty feet; the large dome will be 150 feet in diameter, and 450 feet in circumference, and is intended to accommodate from 6,000 to 8,000 persons. At the Gardens, the foundations of the conservatory have for some time been in course of construction, and will probably be completed in a fortnight or so. The conservatory is to be erected near the main entrance gate, and it is expected that it will be opened in time for the forthcoming international show of fruit and flowers to be held in it early in September next.

Garden Plans.—The Scarborough Cliff Bridge Company offer premiums for designs for laying out their recently-acquired property beyond the Spa, in connection with the existing grounds of the company. A hundred pounds are offered for the best, and fifty pounds for the second best design, to be determined by the committee of the company—the first premium to merge in the successful competitor's commission if his design is carried out.

Monsieur Goutier.—This excellent French gardener died the other day, at the age of seventy-two. It was he who first pointed out the use of sulphur as a remedy for grape mildew, a fact in itself sufficient to make his name remembered with gratitude; but that is not all, he also was the means of improving many of the garden implements employed in his time, as well as an inventor of heating apparatus.—*Revue Horticole*.

Simpson's "Wortley" Celery Collars.—These are designed as substitutes for the various unhandy contrivances in the shape of bay-ropes, moss, tiles, rags, &c., that are frequently resorted to for protecting Celery before earthing up; they are made of stout brown paper that will last for months in the ground, and which may be afterwards incorporated with the soil as manure. They are furnished with a hook at one end and a row of holes into which it clasps at the other. When put on and hooked they prevent the Celery from coming in contact with the soil, keep it clean, greatly lessen its liability to rot, protect it from slugs, and secure a better blanched and more compact head, containing a much greater eatable bulk. They are easily and expeditiously fixed, and greatly facilitate the earthing-up process, but they will also blanch Celery effectually without earthing up; so that the earlier batches that are used, before severe frost sets in need not be soiled up at all, unless desired. These collars will yield to the plant as it increases in thickness, by the hook pulling through into the next hole; but it will be found, in practice, that the paper resists considerable distension, keeps the leaf stalks firmly in their places, and secures a clean, compact, and well blanched sample, that more than repays the small outlay in collars. As regards application, while one man gathers the leaves up firmly in his hands another slips the collar on, taking care to slip the hook into the hole that secures the proper degree of tightness. A collar should be put on each time the plants are soiled up, and about half an inch should be left above the soil for the next collar to lap over. It is recommended to use the narrow-sized collars for the first earthing, and not to hook them so tightly as those put on later in the season. The first size measures 3*3* by 9 inches, the second, 4*1* by 9 inches, and the third 5*1* by 9 inches; the low price at which they can be sold brings them within the reach of everybody.

LAW NOTE.

Hemsworth v. Mann.—This suit was instituted by a gentleman who was lessee of the right of shooting over a farm in Suffolk, containing about forty acres, of which the defendants were tenants. The tenants had entered into a covenant by which they undertook to preserve the game, and had raised a bank three feet high around a considerable portion of the farm. On the bank they had put up wire fence, two feet high, on every part of which they had twisted a quantity of fern and cuttings of fir, so as to make it impossible for any running game to jump over it. In the bank they had dug burrows in which they had set up traps. The plaintiff alleged that the raising of this bank, &c., was a violation of the covenants into which the tenants had entered. Lord Romilly was of opinion that in respect of the raising of this bank, &c., the tenants had not violated their covenants. The court saw nothing whatever in the lease granted to the tenants to deprive them of the right of putting up a species of fence, which they said was put up to protect their crops, and not at all with the view of injuring the game. The court was of opinion that under these circumstances this was a suit which ought not to have been instituted, and the bill must be dismissed with costs.

FAMOUS TREES.

THE PAGODA FIG OF INDIA.

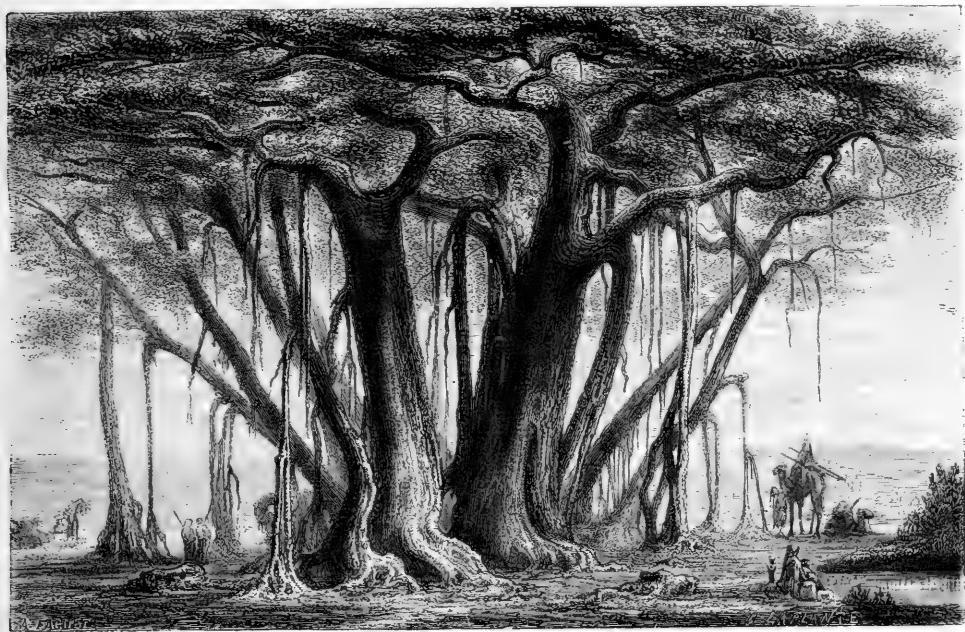

(FICUS RELIGIOSA.)

EFFORE—very long before modern botanists had classed the vegetable productions of India—separating them into genera and species, according to our present scientific methods—the ancient priests of the land had given native names and attached popular legends to many of the more remarkable trees of that teeming soil. The *Ficus religiosa*, whose vast and far-spreading limbs put forth subsidiary branches which descend to the earth, and form additional trunks for their support, often assumes the aspect of a vegetable temple, formed by a roof of dense foliage, supported by countless columns; producing a far extending and grateful shade, which, in a tropical climate, is so desirable, and so greedily sought

fittingly designated as that of the earthly birth of their pagod Vishnu, than one situated beneath the shades of the columned fig tree? It was, in fact, beneath the green roof of the *Ficus religiosa*, as carefully recorded in the sacred books, that the birth of Vishnu was made to take place; the tree itself being pronounced holy, and the breaking of a branch, or the plucking of a single leaf, declared a sacrilegious act of the most heinous character. Hence it was called *Pippul*, or the *Pagoda tree*. This sacred legend was well-known at a very early period, even to Western nations, and is mentioned by Herodotus; to whose industrious researches, more than four hundred years before the Christian era, we are indebted for so many interesting facts connected with the history, the arts, and religious institutions of the early races of man. It is also referred to by Pliny and Strabo.

The trunks of the Sacred Fig, when young, are round and smooth, but in age they exhibit perpendicular ridges and hollows alternately, presenting the appearance of the clustered columns of Gothic cathedrals; the ashy colour of the bark tending to favour the illusion, as resembling that of grey stone. The leaves are about six inches in length, and of a dark shining green; their stalks being long and slender, cause them to have a tremulous motion with the slightest breeze, like those of the Aspen—the rustling sound thus created adding to the impressive effect produced by the aspect of the columned shades of these tree-cathedrals.

GLENDOVER OAK

The Pagoda Fig.

by the wayworn traveller. An imaginative priesthood, with the lively perceptions of an Eastern race, was not slow to perceive the singular and impressive aspect of this many-stemmed tree, in the deep shadow of which the camel driver rested with his beast during the burning heat of the midday sun. Beneath which, in fact, a whole caravan might repose, and enjoy the refreshing coolness afforded by the natural canopy formed by the foliage of its matted branches; for thousands of yards are covered by some of the larger specimens of this giant tree. What spot could they have more

The fruit is not larger than a cherry, and of a purple colour when ripe. But, though not unwholesome, it is not esteemed edible. Roxburgh, in his "Flora Indica," speaks in terms of wonder of the great size of the *Ficus religiosa*; stating in the same place that it is found all over India, even on the mountains; but that it is most common near houses, where it is systematically planted for the sake of the deep and grateful shade which it yields.

The *Pippul*, or Sacred Fig, may be easily distinguished from the *Banyan*, which it resembles in general aspect, by the

manner in which the new trunks are formed. In the Banyan, slender roots are shot down from the horizontal branches, which do not become branch-like or tree-like till after having struck into the earth; while the Pippul sends down true branches earthward, the rounded ends of which are furnished with a large spongiola, which becomes the nucleus of a new set of roots as soon as, by the continued downward growth of the descending branch, it reaches the ground. Blume describes a gigantic specimen of *Ficus religiosa* in Java, near a place called Bata Tulies, from the branches of which he gathered thirty-four species of parasites and epiphytes—stating that he might easily have collected full as many more.

Some of the trees belonging to the species *Ficus*, especially the Pippul and the Banyan, furnish (with the sole exception of the Palms) the most characteristic features of tropical scenery. Their complex appearance—with their far-stretching horizontal branches supported by additional trunks in every stage of growth, from the slender proportions of a Byzantine column to the massive proportions of the imposing Doric, at once arrests the attention of the spectator; while embryo columns, still pendent from the parent branch, furnished with their enormous spongioses, ready to fix themselves in the solid earth and secure a permanent foundation, are very remarkable, and never fail to produce a striking impression upon travellers who witness their aspect for the first time.

The milky juice of many of the fig family has caused the name of Cowtree to be given to some species, especially the *Ficus elastica*, the coagulated "milk" of which forms the India rubber of commerce.

The *Ficus religiosa* has been cited as an emblem of the vastness and unchanging character of India. Its extreme longevity is extended *ad infinitum* by the continuously created new stems as sources of fresh and additional vigour, rendering its destruction by age seemingly impossible. The duration of the Oak, and of other "long-lived" forest trees is, in fact, but a span compared with the perennial life of the Sacred Fig; several well-known specimens of which are calculated to have endured for at least three thousand years. It may, indeed, be considered to rank among the foremost marvels of vegetable creation.

H. N. H.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Coning of the Umbrella Pine.—It may interest your readers to know that the *Sciadopitys verticillata* (Umbrella Pine) has come upon it in the Knap Hill Nursery, Woking. They are produced singly at the points of the shoots. Have any of your correspondents heard of its coming in other parts of the country?—G. T.

Absence of Mistletoe in Devonshire.—Would Mr. Gordon have the kindness to state whether he can assign any reason for the remarkable absence of *Viscum album* from the orchards of Devonshire? From my own personal observation, as well as statements of others, it seems to be almost unknown, whereas the parasite can be seen in countless numbers upon the apple trees of Worcestershire and Herefordshire. I have before drawn the attention of naturalists to this subject, but they could throw no light upon the matter. I suppose the geological conditions of these two counties are pretty similar as far as regards the red or Devonian sandstone.—C.

Remarkable Yew Tree.—The following are the dimensions of a grand old Yew tree growing on the Marquess of Bath's estate in Wiltshire:—Height, 50 feet; circumference of branches, 164 feet; spread of branches from north to south, 53 feet; and from east to west, 60 feet; girth of stem at one foot from the ground, 33 feet; smallest girth of stem, 24 feet 6 inches; length of stem, 7 feet. Under ordinary circumstances the age of Yew trees may be approximately guessed at, by allowing a century for every foot in diameter of stem, thus this famous old tree may safely be calculated at from 1,100 to 1,200 years old. It is a growing healthy tree, rather cone-shaped, and is very dense in foliage. I should be glad to learn through your columns whether any of your correspondents know of a larger Yew tree than the one I have just recorded.—GEORGE BERRY, Longleat.

Planting in the Yorkshire Moorslands.—Will you kindly furnish a list of the better sorts of forest trees for planting in a park, with a view to the improvement of the landscape? I want really hardy trees, and not those so called, as half the kinds named hardy in "Loudon" fail here in the wilds of Yorkshire, on the limestone soil. Of course, I know the commoner sorts, such as purple Beech, variegated Sycamore, *Acer Negundo variegatum*, red Horse Chestnut, but what I want are the more rare sorts which have been proved hardy.—CRAYEN.—[We presume you are located in close proximity to some of the high Yorkshire moorlands; and, judging from your inquiry, it would appear that your endeavours towards landscape effect have hitherto been somewhat unsuccessful. Perhaps, however, your want of success should not in all cases

be attributed to the tenderness of the plants selected; there are various other causes which possibly may have had a share in the matter. In offering the appended selection—which we do from a pretty extensive Yorkshire experience—we would venture to offer a word of advice, namely, prepare the ground well—do not stave your plantations. Trees like a liberal diet as well as other plants. Plant small material, rather than aim at effect at once—have faith in nature's power to adapt the growth of a young plant to its new locality, mind we do not say acclimatised; and when you do plant, select nice damp, autumnal days for the operation; see that your men know how to plant, not to "stick them in" at so much a thousand. Care and dash with this process are not inimical to one another; finally, remember that weeds grow during summer, and that they may, under the name of protecting, be really smothering the young growth; also that good stirrings to the surface of the soil three or four times during summer do good. The trees we would recommend you to plant are:—

<i>Acer Pseudo-Platanus</i>	<i>C. tanacetifolia</i>	<i>P. aucuparia</i>
<i>A. P.-P. variegatum</i>	<i>C. coccinea</i>	<i>P. pinaster</i>
<i>A. pseudoplatanus</i>	<i>C. Arborescens</i>	<i>P. plautifolia</i>
<i>A. Wegmannii</i>	<i>C. glandulosa</i>	<i>P. Poulayana</i>
<i>A. stituum</i>	<i>C. double scarlet</i>	<i>P. argentea</i>
<i>A. rubrum</i>	<i>C. single scarlet</i>	<i>P. canadensis</i>
<i>Fraxinus excelsior</i>	<i>C. Paul's crimson</i>	<i>Amelanchier Botryaprum</i>
<i>F. aculeatissima</i>	<i>Ulmus monspelialis</i>	<i>Cornus masnana</i>
<i>Fagus, fernleafed</i>	<i>U. siberian</i>	<i>C. sanguinea</i>
<i>Betula alba</i>	<i>Cytisus Laburnum</i>	<i>Douglasia</i>
<i>B. pendula</i>	<i>C. laburnoides</i>	<i>Prunus Padus</i>
<i>B. lenta</i>	<i>Tilia alba</i>	<i>Euonymus europaeus</i>
<i>B. laciniata</i>	<i>T. sanguinea</i>	<i>Cedrus atlantica</i>
<i>Cherry, double blossomed</i>	<i>T. pyramidalis</i>	<i>Pinus austriaca</i>
<i>C. Mahaleb variegata</i>	<i>Quercus coccinea</i>	<i>P. Cembra</i>
<i>Betula (Pavia) flava</i>	<i>Q. Cerria</i>	<i>P. pumila</i>
<i>Zelkova</i>	<i>Q. Lucombeana</i>	<i>Pices Nordmanniana</i>
<i>Zelkova macrostachya</i>	<i>Q. Petiolaris</i>	<i>Thuja gigantea</i>
<i>Corylus Crus-galli</i>	<i>Q. laurifolia</i>	<i>Thujopsis borealis</i>
<i>C. pyracanthocephala</i>	<i>Tyrus (Sorbus) aria</i>

THE KITCHEN GARDEN.

THE CUCUMBER—ITS CULTIVATION AND USES.

(Continued from page 425.)

PRINCIPLES OF CULTIVATION.

THE principles concerned in the cultivation of the Cucumber are such as are involved in the cultivation of all other plants, namely, light, heat, air, and moisture. Light is certainly the most essential element of success, for without it all other aids to cultivation are of no avail, and the plant soon perishes. "It is," says Lindley, "to the action of leaves, to the decomposition of the carbonic acid and of their water; to the separation of the aqueous particles of the sap from the solid parts that were dissolved in it; to the deposition thus effected of various earthy and other substances, either introduced into plants as silex or metallic salts, or formed there as the vegetable alkaloids; to the extinction of nitrogen; and probably to other causes as yet unknown;—that the formation of the peculiar secretions of plants of whatever kind is owing. And this is brought about principally, if not exclusively, by the agency of light—their green colour becomes intense in proportion to their exposure to light within certain limits, and feeble in proportion to their removal from it, till, in total and continued darkness, they are entirely destitute of green secretion, and become blanched and etiolated." This explains the difference in the growth in the subject of these remarks, especially between midsummer and midwinter. At the former season, in our gloomy atmosphere, the only danger is that of the light at times being in excess of the resistive power of the tender foliage, and hence it may get scorched; but in midwinter the light at times is insufficient to promote the necessary deposition of substance, and, consequently, the growth is weak and etiolated. It may be regarded as an axiom in cultivation that the health of other parts of a plant is in proportion to the health of the leaves; and hence without healthy leaves we cannot have healthy fruit. There is no exception to this rule, and the neglect of it is the constant and fruitful parent of failure. From this will be perceived the immense importance of keeping the glass of a cucumber-house as clean as possible during the winter season, and to insure perfect fruitfulness through the winter the plants must be thoroughly established before the dull weather of November sets in, every leaf upon them at that season being exposed to as much light as possible. Much, however, as the Cucumber requires light in the winter season, to enable it to bring its growth to maturity, it is a question whether in the early spring and summer months an excess of it is not the

cause of one of the diseases from which the plants suffer, viz., "chlorosis," or a shrivelling up of the leaves without any apparent cause. Be that as it may, experiment has demonstrated that if we darken the house by shading the glass with a fine net, or coating it with a thin wash of size with a little whiting in it, the virulence of the disease is abated; but expose the leaves to the power of the sun for only one hour and it is more than probable a large portion of them will be destroyed. We hope we have said sufficient to show the indispensability of light to the successful growth of the Cucumber in the winter season, and the wisdom of its modification in the summer.

HEAT.

As the Cucumber is a native of a tropical climate it necessarily requires the protection of glass, except in the very height of the summer. The earth heat, to secure the best results, should not be less than from 75° to 85°, but beyond the latter temperature it is not wise to go, as a greater temperature only tends to etiolation—a lengthening of the parts of the plant without adding much to the substance. The day atmospheric temperature without sun should not exceed the terrestrial heat, but when the sun is shining it may rise to even 90° or 100° with the best results. Temperature, however, must be to some extent modified by the state of the atmosphere. When the weather is dull the temperature must be lowered, but when it is bright and clear take advantage of it to promote growth as much as possible. Heat, without light, is comparatively useless; but heat, with light, is the condition which insures perfect success. The reason why heat is necessary to plants in a growing state is, that warmth acts as a stimulus to the vital forces, and its operation is in proportion, within certain limits, to its amount. Warmth, remarks a German writer, is not really a stimulus to vegetation, but it is extremely necessary for the solution of various substances with which the water comes in contact. It also sets free certain gases which the leaves take up, and through these sources of nourishment promotes the growth of plants. Such being the fact it is obvious that the cultivator's first care should be to secure the means of insuring a proper temperature to the soil in which his plants grow, and the atmospheric temperature should be in a proportionate ratio.

A.

(To be continued.)

SEAKALE IN MARKET GARDENS.

SEAKALE is now (March 16) obtained abundantly from the open ground. In market gardens the seed is sown thickly on four-feet beds in March, and throughout the rest of the year the young plants are allowed to remain in the seed bed without thinning until the following spring.

Though their thickness in the seed beds renders them weak, yet they are preferred, as they are not so liable to run to seed throughout the summer. These seedlings are now being lifted, their roots shortened a little, and planted with a dibber in well-prepared ground, one foot apart each way. Here they are allowed to remain until winter, and every encouragement is given to them, by keeping the ground free from weeds, and frequently stirring the surface.

In winter, or as soon as forcing begins, every second two lines are taken up for that purpose, and the two remaining ones are earthered up from the spaces now vacant, placing about six or eight inches of soil over the surface, much in the same manner as Asparagus beds are done. As soon as the shoots appear above this ridge, the soil is forked aside, and the shoots are cut clean off, taking with them the top of the crown. After cutting, the crowns are not covered again that season, but a great many young shoots soon sprout up all round the crown; these are all removed, except two or three at the most, which are allowed to remain. Under this treatment they afford good produce for several years, and the greatest care should be taken to guard against ruining the strength of the crowns, by leaving too many young shoots. The second and third years of earthing up afford the strongest and best produce.

W. F.

I SMOKED my lettuce-plants at morn,
At fervid noon, and dewy eve;
Not as Tobacco—that I'd scorn!
But to make creeping creatures leave.
Taking my leaves, and not their own,
Two fat old grubs appear'd to say,
Whilst preying on my lettuce prone,
Grace over meat—thus, "Lettuce prey!"

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Tan.—To what uses can tan be put in a garden?—J. K.—[Fresh tan is a good material for supplying bottom heat to plants in pots plunged in it. Spent tan is almost worthless in a garden. We know of no good use to which it can be put, except, perhaps, to mix in heavy clay lands.]

Mushrooms in Pots.—I am acquainted with a gardener who grew not long ago some beautiful mushrooms in pots, by accident as it were. In the spring of last year, after removing his old beds, he selected some comparatively spent spawn, and placed it in large pots, which held a bushel or so, setting them, or rather storing them, away in a dry shed. During the summer-time, having occasion to look after them, to his surprise he found the pots plentifully supplied with beautiful mushrooms.

—JABEZ JAY CHATER.

Use of Gas Lime as a Manure.—Is lime used in purifying gas of value as a manure for an old garden, or an old lawn? If so, how should it be applied?—D. F.—[The lime used in purifying gas is used as a manure. It is considered good for cold, heavy land, and has the effect of killing wireworm and obnoxious insects. Four tons to the acre is the quantity usually applied. In some cases it is dug in as soon as it is put on the land; in others, left during the winter. It is so far powerful that, if allowed to remain in heaps, nothing will grow where they have been for some time. It cannot be used with safety as a surface dressing; it would certainly be unadvisable to employ it on a lawn. It might be used in old garden ground; but it must not be put near the roots of fruit trees in old fresh state.]

THE FRUIT GARDEN.

PRUNING NEWLY-PLANTED TREES.

In the case of most fruit trees, excepting maiden trees—*i.e.*, young untrained ones—a prior question might often be asked, viz., is it necessary to prune the top at all? Certainly it does not seem a very philosophical practice to plant a nice tree with a view to covering a given space with fruit, and then immediately proceed, as is often done, to cut it all to pieces. Such treatment might be useful for forest trees, but is certainly worse than useless for fruit trees. It can only tend to the production of gross wood, and is certainly antagonistic to fertility. Still maiden trees must be pruned or cut back, and in doing so there are three things to be borne in mind. The first is that the tree should be pruned to grow; the next that it should be made to grow in a right direction; and the last that it should grow to a useful purpose: in other words, the tree must make wood, acquire shape, and become fruitful. Another preliminary is, where and what shall we prune—the top or the root? Our answer is, both—the former chiefly as a means of forming the tree into shape, the latter mainly as a certain mode of throwing it into fruit. Transplantation is the most radical mode of root pruning, and consequently the most potent means of inducing fertility, provided always that the top is not too much reduced at the same time. Some planters contend for a reciprocity of mutilation of root and branch. Were wood only our object, this would be a safe rule; or rather the head of the tree might be reduced more than the roots. But as the production of wood in fruit culture is only a means to the chief end—the insuring of fruit—the reduction of head should be less than the deprivation of roots. Only practical experience can determine how much top the partially mutilated roots of any given tree can healthily sustain. Very much depends not only on the number, but also on the condition of the roots. If the trees are moved at home, and planted immediately, little, if any reduction of top will be needed; whereas if the trees have travelled far, or grown very closely together in a nursery, or been carelessly taken up, a greater reduction of head will be desirable. Much will also depend upon the future care of the roots. It is of the highest import that these should be protected from frost, drought, and rupture. With such care they will support double or treble the area of top which they could nourish under other conditions. And the larger the top the newly moved roots can support, the sooner a fertile habit will be induced, and the more certainly will this fertility be perpetuated.

Another consideration will, however, influence the extent of this cutting in or pruning of young trees—they must be made to grow into the desired form. Now the first step towards a perfect shape is the furnishing of the base of the tree with wood. It is a common saying with fruit-tree trainers: Take care of the bottom and the top will take care of itself. This is perfectly true, and originates in the fact that nature is bent

upon raising the tree straight up into the air rather than spreading it horizontally abroad over the earth. But on garden walls and such surfaces, whether tall or dwarf, the first branch is wanted to run parallel with the surface of the earth at a distance of only six inches or a foot from it. This fact, then, must control the nature and extent of the cutting back. The entire shoot of the young tree is furnished with living buds; but if allowed to remain throughout its whole length, only the highest buds on the branch will break or grow into other branches. Left to itself, the buds on the stem lower down would continue dormant for ever. They would not, could not, break into shoots, and therefore the tree would have no base. To make the bottom buds break the top must be removed. This operation is termed cutting-in the young tree. The severity or otherwise of the process should be controlled by the height of the space to be covered, the character of the trees, and the distance they are planted from each other.

The character of the tree is the most important consideration, as it determines both height and distance, and should be settled in the mind's eye before a knife is allowed to touch the tree. Is it to be a rider or a dwarf, a bush, a horizontal, a fan, a pyramid, or a common orchard tree? In some cases we require a long, straight, naked stem; in others the shoots to break forth from quite near the surface of the earth. Frequently, in case of wall trees, the first thing we have to do is to lay a young shoot along the lower part of a wall; and to make it break regularly is an important consideration. This we may often manage, by bending the shoot or shoots downwards. Thus, for instance, if the young shoot is laid along the wall in the position it is eventually to occupy, it will probably fail to break in some parts of its length, and grow freely in others. This is objectionable. Suppose the buds near the base of the shoots will not break, we may force them to do so by bending down the point of the shoot, so that the eyes that refused to bud forth are left more elevated than the parts which were growing freely. This forces the dormant eyes to open, and then, after a while, we may raise the shoot to its allotted position. Paradoxical as it may appear, the smaller the tree the less severely it should be cut back; consequently, fan, vase, or bush-shaped trees, with many shoots, must be more severely cut back than cordons or dwarf espaliers, with only a few.

What are termed riders are introduced to fill up vacancies on the higher parts of walls or fences, and hardly require a base. Their mission is temporary, and their upper portions alone are valuable. This fact, of course, will determine the character of their pruning. They will often need little or none. In vase or bush formed trees, again, the length of the stem will influence the extent of the cutting back; some may prefer a stem a foot, others two or three feet, high. It is also important, in forming such trees, to secure, if possible, enough shoots at once to form their entire framework; from four to eight shoots will generally suffice. It is well to twist or bend the leading shoots, to obtain these branches of nearly equal strength. Their leading shoots should also be bent outwards and downwards, to impart the proper form, develop the buds at their base, and to prevent overcrowding. This bending will reduce to a minimum the amount of cutting back the second season. The pruning of pyramids, again, differs from any of these. The form even modifies the nature and extent of the cutting. A well-developed straight central stem, with a regular succession of nicely-balanced fruitful side branches, is the *beau ideal* of a perfect pyramid. Width of base must be secured at starting; no after pruning can give it if not secured at first. This, with a healthy leader cut fearlessly in to furnish sufficient side branches, is all that is required to obtain good pyramids. When the trees are in vigorous growth, this leader should be stopped at least twice during the summer. Such stoppings will each produce crops of side branches; and then at the winter pruning, five or six inches or a foot of the leader may be left to produce another tier or two in the spring, and so on in continuity until the desired height and size are reached.

The most severe pruning should be reserved for the common fruit trees for orchards. The larger a tree is ultimately to become, the harder it must be cut back at starting. Such practice concentrates vital force, collects the entire energy of

the plant into a focus of growing power; and for such trees strong vigorous growth is the first point. This lays a broad, healthy, solid foundation for quantity and quality of fruit in the future; it gives the tree a firm grip of the earth, and imparts stamina and constitution to the entire plant. This growth may readily be moulded into shape, and diverted into a fruitful channel—not, however, by the direct application of the knife after it is perfected. Summer toppings, mechanical twistings or bendings, and root pruning, are the grand panaceas for barrenness, and the direct promoters of fertility. Growth and the form of it are amenable to the laws of the knife and the rules of training; but fruitfulness cannot be thus directly summoned forth at our bidding. To insure fruit, we must go deeper, and aim at the roots; a wise application of the knife among these never fails to turn the entire energies of the tree into a fruitful channel.

F.

A GERMAN SCHOOL OF GARDENING.

BY T. SCHWANN.

"In science the German gardener is decidedly in advance of any other in Europe; and in the routine of practice he is surpassed by none in steadiness, or, where he has leisure and is properly encouraged, in order and neatness." So wrote London, some twenty years ago. Foremost among Government schools for gardeners and fruit-growers on the Continent may be named the Pomological School of Proskau in Prussian Silesia, represented by the sketch on next page. It is connected with the well-known Agricultural College of the same place, and affords accommodation for a staff of teachers and thirty-six resident students. As it is the object of the school to provide suitable education for all classes of cultivators, for convenience of study it has been divided into the three following departments:—
1. School for gardeners (market gardeners, nurserymen, fruit-growers, &c.); 2. Superior school of horticulture and pomology; 3. Section for teachers, so called "superintendents of trees," and their assistants.

To enter the first division, the applicant must be over seventeen years of age, and bring with him proofs of having attended for at least half a year some school. If not provided with the needful certificate, he must be tested by an examination as to the amount of elementary and general knowledge he possesses, and in case of non-proiciency, takes his place for six or twelve months in a preparatory class. In the latter, the instruction includes, in addition to the "three R's," and a little Latin and French, demonstrations in vegetable, vine, and fruit-tree culture, practice in distinguishing different varieties of fruit, &c. It is, of course, an advantage when the pupil has had some previous experience in practical gardening, but this is not made a *sine qua non* of admission to the institution.

The programme of the School for Gardeners embraces, (1) as preliminary and fundamental branches of study:—Botany, chemistry, geology, physics, mineralogy, zoology, arithmetic, and mathematics; (2) as chief or special branches:—Culture of plants with reference more especially to the raising of garden and orchard produce; knowledge and nomenclature of fruits; choice of the most useful varieties of fruit, their requirements as to climate, situation, and soil; raising, planting, pruning, training, and general management of fruit trees on the roadside, and in the nursery, orchard, garden, orchard house, hedge-row, and open field (under grass or tillage); knowledge of the diseases and noxious insects affecting fruit trees and vegetables, and of remedies against the attacks of the same; forcing of fruit; gathering, storing, drying, preserving, packing, and transport of different kinds; culture of the grape vine and smaller garden fruits; profits derived from fruit culture; manufacture of cider, perry, and various wines; vegetable culture, including forcing; floriculture; growth of industrial crops; arboriculture; landscape gardening; laying out of vegetable gardens and nurseries for fruit trees; plan-drawing, surveying, and levelling; (3) as auxiliary branches:—Book-keeping, apiculture, and the rearing of silk-worms, the latter accompanied by demonstrations.

Students of the second division, or superior school of horticulture, do not attend lectures on general fundamental subjects at the institution, but merely those on the special branches of the curriculum. The general preliminary subjects may be studied by those young men who have not passed through the first section of the school at the adjoining agricultural college.

The complete course extends over four years, two of which are spent in the lower, and two in the upper, division, and, previous to leaving the establishment, each student is admitted to a final examination, and receives a certificate testifying to the degree of proficiency he has attained.

The instruction given in the third section is chiefly of a practical

character, and relates more particularly to operations connected with the raising and improvement of fruit trees, and the management of coppice woods, plantations, orchards, &c.

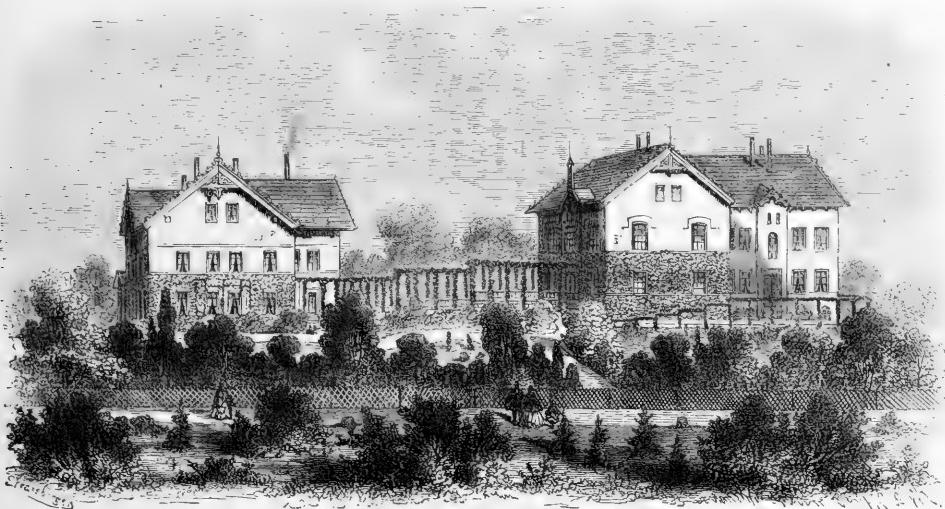

It is divided into two courses—a spring and summer one for the superintendents of trees above alluded to and their assistants; and an autumn one, for schoolmasters and pupils of training establishments for teachers.

In explanation of the fact that these classes of students—the superintendents and teachers—attend the institution in sufficient numbers to induce the authorities to form of them a division apart, it should here be mentioned that many parishes in Germany possess woods and orchards of considerable extent, and requiring for their management competent fruit-growers and arboriculturists, give the preference to young men who have distinguished themselves at well-known pomological schools. The salary of the superintendents of trees ("Bäumwarter," as those appointed are called) amounts usually to about £30 per annum, and they are expected, when remunerated for their services at a certain fixed rate, to undertake the care, not only of the parish nurseries, plantations, &c., but also of those belonging to private individuals resident in the parish. It often happens that several parishes agree to appoint one superintendent among them, he entering into a contract to find his own tools and assistants.

As regards the charge for instruction, for pupils of the preparatory class it is £3. 5s. per session, and for students of the School of Gardeners, £1. 10s. for the first and second, and £3 for the third and fourth sessions. Resident students being expected to take part in the operations of the garden-farm, pay nothing for their board, and the fee for lodging, fire, gas, washing, and all other necessaries together, only amounts to £2. 6s. per annum. The terms of admission to the second section are £6 for the first, £4 for the second, and £3 for the third and fourth semesters; whilst, on the other hand, the course of the third division, those instituted for schoolmasters and superintendents of trees, are entirely gratuitous. In the case of "hospitants," practical working gardeners, amateurs, garden proprietors, and others desirous of attending only one particular course, the fee varies with the position of the individual, and is fixed by the director.

The farm attached to the institution covers about sixty acres, and affords the student, in its nurseries, orchards, plantations, fruit and kitchen gardens, shrubberies, stoves, orchard and greenhouses, &c., ample opportunity of familiarizing himself practically with the operations and modes of culture described in the lecture-room. Although not conducted with a view to profit, the produce raised on it is disposed of at the market price.

The facility with which young men on leaving horticultural and

A German School of Gardening.

The attendance at Proskau of students intending to become schoolmasters is accounted for, on the other hand, by the necessity the latter are under—if they desire an appointment in any Government parochial school—of being able to give elementary instruction in field, garden, and orchard culture.

The rural preparatory schools, as is the case with some of the *écoles normales* and *primaires* in France and Switzerland, have an orchard ground or garden attached to them, and the district school inspector must report periodically whether the same are properly utilized for educational purposes.

Of the two buildings which the above sketch represents as connected by a miniature colonnade, and surrounded by tastefully laid out grounds, that to the right is occupied by the resident teachers and pupils; the other contains the private apartments of the director, and the lecture hall, library, cabinet of natural history, and collections of different kinds belonging to the institution. On the director devolves not only the duty of controlling and superintending every department of the school, but also that of assisting in the work of tuition. Instruction is also imparted by professors of the Agricultural College, as well as, of course, by the resident staff of teachers, who have under them a number of skilful practical gardeners.

pomological schools, such as those of Proskau, Carlsruhe, Reutlingen, Potsdam, and Klosterneuburg, obtain remunerative appointments in all parts of the Continent, testifies to the high estimation in which the above institutions are held, not merely as places of scientific and theoretical study, but also as practical training establishments. [When shall we have Government institutions of this kind in England?]

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Fruit Tree Suckers.—Can I bud or graft on these choice sorts of fruit?—W.—[Suckers are sometimes used as stocks for budding or grafting upon; but they are inferior to seedlings for that purpose, as they are always more liable to reproduce suckers, and they have not the thrifty vigorous habit and the same power of forming as good roots as seedlings.

Wash for Old Fruit Walls.—The walls in our old garden have become so full of nail-holes from long use that they harbour insects, I am afraid, to a great extent. How can I improve them without much expense?—SOUTH HANTS.—[Wash them with a mixture of Portland cement, grey lime, and copperas, which will not only fill up the nail-holes to some extent, but will also help to eradicate the insects. The mixture can be made of a lighter or darker tint, according to taste, by adding to it a little more or less yellow-ochre.]

Seedling Fruits.—Why do not our different varieties of fruit reproduce the same from seed? Why, if we plant the stone of a greengage plum, will it not always produce a greengage plum?—**Fucus.**—[Because of the principle of variation that exists in nearly all living things. But we cannot tell why the product of the stones of the same plum tree should differ from each other, any more than we can tell why puppies of the same litter differ from each other. We can see, however, that the principle of variation is often stronger than that of inheritance of common features.]

Cranberries.—I want to form a bed of these. Which sort is best, the European or American? and in what soil do they best succeed?—**Hedger.**—[The European Cranberry is in every way inferior to that which is so common in the swamps of New England and on the borders of American inland lakes; what is called there the "bell-shaped," which is a variety of *Oxyeoecus macrocarpus*, is the largest. For tarts and preserves this kind is much esteemed. Although naturally it grows mostly in mossy, wet land, yet it may be easily grown in beds of peat made in any rather moist situations, and the berries will be increased in size if a little thoroughly rotted manure is added, and well incorporated with the soil. A small bed will supply as much fruit as an ordinary family is likely to want. In the kitchen garden at Heckfield is a bed near a cistern, from which it can be flooded. It consists of peat, and produces fruit in abundance. It is thought the plants bear all the better for being well watered when the fruit is setting.]

THE FLOWER GARDEN.

FLOWER GARDENING OF THE PRESENT DAY.

BY T. BAINES.

THE arrangement of flower gardens upon what is popularly known as the "bedding system" has of late years met with almost general adoption. Every quarter of the globe has been placed under contribution to furnish something to work out the present elaborate arrangement. It would be difficult to point to a single plant, grave or gay, old or new, that showed any disposition to submit to the necessary manipulation that has not been pressed into the service. It is true that from the first some, attached to old-fashioned flowers, unwillingly banished them to make way for the modern system; and even when some of their cherished friends were retained amongst the host of novelties that soon presented themselves, they could not enjoy their company, or look upon them with so much satisfaction as when seen under more natural conditions. Lately, too, we have heard numbers admit that they have been too much influenced by that most despotic of tyrants, Fashion. Let us ask the question: Is the present system sound in practice, or in accordance with refined taste? Does it agree with the teachings of those admitted authorities, the Reptons, the Browns, the Loudouns, and others, who made British gardening a life study? or is it merely the offspring of that love of change which, alike regardless of the ruling principles of true art and correct taste, has impelled us to adopt a system diametrically opposed to both? The subject is important. Let us view it dispassionately. From the broad landscape of a thousand acres down to the smallest *parterre* the arrangement should be in accordance with the teachings of that unerring guide, Nature. As applied to the general principles of culture, this is an axiom that meets with general assent; the same rule is applicable to the arrangement of every plant, individually and comparatively, with the whole of the different subjects that go to make up the picture which, let it be large or small, ought to be governed by the same law. Is such the principle upon which the flower gardening of the present day is carried out? Nay, rather are not all the teachings of nature often in the arrangement of colour, and more generally in the disposition of form, ignored to an extent that would imply that all our preconceived notions of gardening were grounded on a wrong basis? Nature abhors straight lines, geometrical formality, and those unnatural combinations of colour which are the most prominent features in the bedding system; and the last phase of carpet-like planting is vastly more objectionable than anything that was attempted on the first introduction of the system. We don't tattoo our faces, simply, I suppose, because it is not fashionable; but we tattoo our gardens with a vengeance. And what advantage does the arrangement of the present day hold over that which existed before? The advocates of the system tell us that the picture is so far perfect, that when once the plants employed have donned their summer garb there is no flaw—noting on the wane, nothing approaching the sere and yellow leaf, such as is always to be seen amongst herbaceous plants. This I grant; and it is the one solitary short-lived advantage, which leaves us for eight months out of twelve at our wit's ends to make all sorts of shifts to cover bare beds with little nursery-like shrubs, or procure quantities of costly bulbs to be arranged in the same formal fashion as the summer occupants. We have so far viewed the system simply as an objectionable innovation, that has supplanted a better, because a more natural, a more refined, arrangement of the flower garden, that, with a great deal less labour,

affords a seasonable charm of something whose beauties we at present realize, while others continually progressing will, in their season, play their part to encircle the year, and so give us a continuous sufficiency in place of the present short-lived satiety.

There is yet another and a most important consideration in relation to the subject—namely, the great increase of labour which the bedding system involves; and in far the greater number of places there is no provision made to meet this additional labour; consequently, it is no uncommon occurrence to see places where all the more useful departments are left in comparative neglect. I recollect once going to see one of the largest bedding places in the kingdom—a place that could count its acres of flower garden and ribbon borders, all one gaudy mass of colour. In front of the mansion, one of the finest landscapes in the country was completely spoiled by the blaze of colour in the foreground, heightened by the glare of coloured gravel paths. In the kitchen garden the walks were bounded by the usual borders, where once had stood numbers of fruitful dwarf apple trees that I had frequently seen in years gone by laden with fruit. These had been moved, to make room for the ribbons, scrupulously exact in every line. The gardener asked me what I thought of it. I said, "Which do you mean—the cultivated crop or the natural one? the ribbons, or the quarters inside?" "Oh, the weeds you allude to," said he; "we have no time to remove them." I made no reply. I had frequently seen the place before the bedding system was introduced, when every department was well carried out. Now, the rows of vegetables could not be seen for weeds, and the gooseberry and currant bushes were grown through and through with thistles. There were fruit and plant houses by the dozen, the latter almost empty, their occupants, the bedding plants, being outside. The grapes, pines, peaches, &c., gave unmistakable evidence that their turn for attention did not come until after the bedding plants were seen to—in fact, the whole of the place was sacrificed to the bedding plants; and there are very great numbers of places where the same thing exists, only in a somewhat less degree. Yet, amongst the different plants that are used in this style of gardening there are many that are individually beautiful, and it would be a mistake to discontinue their use in moderate quantities, artistically arranged for summer decoration. It is the absence of such arrangement, coupled with a general crowding and an undue breadth of colour, that gives no repose. What do we generally find? A piece of ground, on which are arranged a number of beds edged with box or stone, real or imitation, intersected by narrow gravel paths; or we find a similar arrangement upon grass, the collective mass of colour occupying the whole space, except the strips of turf between the beds; instead of the beds and their occupants being confined to something like one fourth, or at most, a third of the whole space, leaving a broad margin of grass so necessary to repose. Far the greater number of modern flower gardens are similar to what a landscape painting would be without sky. In place of straight lines of colour, panels, or chains, in the different beds, an irregular admixture in each bed of several plants, different in form and colour, are infinitely more effective to the well-trained eye.

I have frequently noticed that at the end of the planting season, when the odds and ends of the whole family of bedding plants employed are planted on a piece of ground, as they sometimes are, without any formal arrangement—something like what the late Donald Beaton used to call his "shot silk bed"—that they looked better than those in the flower garden. If my memory serves me right, Mr. Beaton's bed was an admixture of *Mangold*'s variegated Geranium, and Purple King Verbena, planted in irregular patches, so as to cover the allotted space, and allowed to run one into the other, without any attempt at training. So far as my own taste goes, I look upon this as the most pleasing combination in the shape of blooming bedding plants.

Oh, yes! I think I hear some one saying; but the difficulty of avoiding the bare beds during winter and spring can be got over without resorting to shrubs or bulbs, by employing some of the numerous hardy herbaceous spring-blooming plants. I answer simply, that when hardy spring-flowering plants are used after the same fashion as the summer bedders, the arrangement is just as objectionable as is the summer bedding system. We sometimes hear gardeners say that the fault of the present system rests with the ladies, who are so much enamoured with it that nothing else will please. To some extent, this may possibly be true; but I am certain of one thing, that twenty years ago there used to be a general striving amongst gardeners as to who should be able to say that he bedded out more plants than his neighbours. If A had fifty thousand, B was not content until he had a hundred thousand; C would out-do both, by using double that number. There is one certainty in the matter, that if gardeners have, in a great measure, brought the system upon themselves, they have had ample atonement to make for so doing. The extra labour it has thrown upon them they alone know.

LOAM A CURE FOR THE VERBENA "DISEASE."

But a few years ago the Verbena was a universal favourite, easily propagated, relied upon as a good grower and permanent bloomer, and, in fact, considered indispensable as a bedding or border plant. Now it is so little esteemed for such purposes, that in many places where it was once grown by the thousand, it is not to be seen at all. How is this to be accounted for? It is not because we have found a better substitute, for among the different varieties of the Verbena we have the richest grades of colour, the greatest profusion of bloom, and plants of a most accommodating habit. But if we ask almost any gardener of twenty years' experience, he will tell us that the Verbena does not grow nowadays as it used to do, and therefore he dare not trust it. This is about the truth. There does seem to be a veritable difficulty in getting it to grow as it once did; and in these days, when a blank in the parterre would be an almost unpardonable offence, the once popular favourite has been discarded. The plants get weak and wiry, the foliage assumes a rusty look, the blooms are few and miserable, and, in fact, the plants refuse to grow altogether. These are the characteristics of the Verbena disease as a general rule, and although it may be due to various causes, I am strongly inclined to think that it is a question of soil principally. In short, I blame leaf mould for being the ruin of the Verbena. Since the present bedding style commenced, and flower beds and borders have had to be cleared annually, it has been the custom to manure regularly for the next season's occupants; and as leaf mould in some form or other forms the staple of the procurable manure for the flower garden, it has been added to our flower beds year after year, until the original staple, a good loam perhaps, has nearly disappeared, giving place to a spongy depth of leaf mould, which is a good compost sometimes when used in moderation, but few plants will thrive long upon it alone. Some plants, indeed, dislike it, and amongst these is the Verbena, which, according to my experience, never thrives on light soil, or in soils where humus is in excess. A loam verging upon clay is far preferable.

Some years ago I received some Verbena plants from a friend which were so strong and vigorous as to make me doubt whether I had got the true variety. I found, however, that their vigour was due entirely to the strong loam, and nothing else, in which the plants were potted. Since that time I have used loam almost pure for the Verbena, when I could afford it, and have never failed to have fine plants and a good display of bloom; while, when our beds have had to go without the usual dressing of loam, my success has only been indifferent, but on such occasions we plant fewer Verbenas. In the dry season of 1868 I had the beds where I intended to plant Purple King and Crimson King Verbenas scooped out a foot deep, and filled with fresh chopped loam, in which a little cow dung was mixed, and the whole turned over with what natural soil was left in the bed. The plants grew with extraordinary vigour, and were one sheet of bloom the whole summer, notwithstanding the trying drought. Our stock plants are potted in sifted loam and sand in autumn, and the spring-struck plants are boxed off in the same material till bedding-out time. It is a bad plan to coddle Verbenas in pots. Our chief difficulty has been to get good cuttings in autumn for winter stock. Last season, having planted but few Verbenas in consequence of our stock of loam being used up for other purposes, we secured but an indifferent stock of cuttings, that have left us short for this season. But in future we intend growing our stock plants on liberally during the summer, without allowing them to bloom; by so doing I doubt not we shall get a good crop in spring. I would strongly advise your readers to try loam for their Verbenas at all stages. In boxing off newly-struck cuttings a little sand may be mixed with the loam, and if the latter is very heavy a slight addition of leaf mould may be added, just to prevent the soil from caking in the boxes. In every case the soil for young bedding plants—of any kind, indeed, that are planted in boxes or pans—should be sifted through a half-inch sieve. The advantage of this will be found at planting-time, as the roots will be easily disengaged from each other; whereas, if the plants had been growing in rough, turfey material, this could not be done without a great loss of roots.—J. S. W., in "Field."

PLANTS TO BE NATURALIZED.

BEFORE introducing a plant into a neighbourhood, those who are carrying out the course recommended in that delightful book "The Wild Garden," should first ascertain its characteristics, whether it be of a rampant or rapidly-growing nature; else they run a risk

of losing old favourites, which will be smothered out, or space will be overrun which may be more profitably occupied. These remarks apply especially to small places, where all waste ground should be beautified by the establishment of hardy free-flowering plants. However attractive many flowers are when occurring at intervals in woodland glades and walks, there are comparatively few of the rampant kinds which can be tolerated in profusion, to the exclusion of their more delicate and precious brethren. I speak feelingly. The Pyrenean Valerian is an attractive flower when it raises its lively green foliage and rosy-lilac umbels of flowers singly or in groups in the shady parts of wild woods, but it becomes a nuisance if allowed to spread to the extent it will if undisturbed, as it has in a small wood under my house. There are several other plants of like habit which are recommended somewhat indiscriminately by enthusiasts in wild gardening, but there are others of which it is impossible to have too many. Wandering one day in the neighbourhood of "Grugifoot," a queer-shaped hill in Lintonshire, my eye was attracted by a small burn whose banks were literally jewelled throughout its visible course with an unfamiliar yellow flower. A nearer approach showed me that it was the garden Mimulus (Monkey Flower), the seed of which must have escaped from some neighbouring cottage garden, and established itself here, in the coldest part of the British Isles. I took the hint, and have naturalized it by the banks of a small stream which runs at the foot of my garden, and I strongly recommend your readers to do the same. It mingles charmingly with the blue Forget-me-Not, and is equally hardy.

SALMONICETS.

EARLY FLOWERS.

The following plants have been in flower in the garden at Drayton-Beauchamp Rectory from February 1st to March 13th:—

Allium Chamomile	Erythronium albidum	Primula vulgaris
Arabis albida	E. dens-canis	(various)
A. arenosa	Ficaria pallida	P. v. double lilac
A. blepharophylla	Forsythia viridissima	P. v. double white
A. glabra	Gagea	P. v. double yellow
A. incisa	Galanthus nivalis	P. v. double French white
A. procurrens	G. plicata	Palmaria vulgaris
A. procurrens variegata	Helleborus atrorubens	P. v. flore albo
A. stricta	H. colchicus	P. grandiflora
A. rosea	H. foetidus	S. b. alba
Anemone blanda	H. niger	S. b. lutea
A. pulsatilla	H. viridis	S. rotundifolia
A. ranunculoides	Hedera helix	S. sibirica
Alchemilla vulgaris	H. triloba alba	Saxifraga oppositifolia
Antirrhinum grecum	H. t. rubra	S. o. alba
A. purpureum	H. t. r. plena	Scleropeltaria verma
A. variegatum	H. t. cerulea	Scopolia carniolica
Babcockium vernum	H. t. c. plena	Vinca minor
B. Plantae	Hypocaccus galathoides	V. m. flore albo
Corydalis speciosa	H. pectinatum (Roman)	V. m. lutea
C. cava pallida	Hyoxyanthus orientalis	Viburnum Tinus
Calendula arvensis	Iberis gibraltarica	Viola blanda
Celsia Arcturus	I. sempervirens	V. hirta
Chrysosplenium alternifolium	Ionopsidium acule	V. tricolor
Chiranthodus Chirai, var.	Lamium maculatum	V. suavis
C. plenum, various	L. galeobdolon	V. semperflorens
C. hybrid fruticosus and	L. galeum	V. v. alba n. pl.
apinae	Mahonia Aquifolium	V. v. n. Marie Louise
(This Chiranthodus is a cross between C. alpinus and C. fruticosus.)	Medicago arborea	V. odorata
Muscari botryoides	Mertensia virginica	V. o. f. albo
M. b. flore albo	Ophiopogon planiscapus	V. o. f. lilacino
M. b. flore pallidu	O. v. pl. carneo	V. o. romana
M. pallens	O. v. pl. cervulco	V. o. ozan
M. racemosum	O. v. pl. albo	V. o. gigante
M. Strangwarsi	O. v. pl. rubro	V. f. pl. Queen
M. moschatum	Narcissus aurantius	Myosotis dissiliitoria
N. minor	Mertensia virginica	Orobis cynucus
N. minimus	Ophiopogon planiscapus	O. v. pl. carneo
N. min.	O. v. pl. sibirica	Sisyrinchium grandiflorum
N. min.	O. v. pl. carneo	Saxifraga cymbalaria
N. min.	Androsace coronopifolia	Phlox procumbens
N. min.	Narcissus ornatus	N. v. bicolor
N. min.	N. v. pl. carneo	Corydalis solidia
P. auricula	Pulmonaria sibirica	Ribes sanguineum
P. corticosides	Ribes sanguineum	R. s. flore pleno
P. denticulata	P. elatior (Jacquin)	R. s. flore pallidu
P. elatior	P. e. (Britain)	Epimedium grandiflorum
P. e. flore pleno	P. e. House in Hose	E. p. grandiflorum elegans
P. e. House in Hose	P. e. marginata	Asterus europeus
P. macrocalyx	P. e. House in Hose	Cochlearia officinalis
P. veris	P. e. marginata	Doronicum Clusii

The Rectory, Drayton-Beauchamp, Tring.

H. HARPER CREWE.

THE HARDY PALM.

WERE we to ask botanists—those manufacturers of species—to be so good as to point out the differences which exist between *Chamaerops excelsa* (Thunb.), *C. Fortunei* (Hook), *C. sinensis* (Hort.), and *C. japonica* (Hort.), they would, we imagine, be for once puzzled. Gardeners would be less so; they would solve the question in these few words: "They are all the same species;" and they would be right. Accordingly, we believe the true synonymy of this species should be tabulated as follows:—*Chamaerops excelsa* (Thunb.), *C. Fortunei* (Hook), *C. sinensis* (Hort.), *C. japonica* (Hort.), *Trachycarpus excelsa* (Wendl.). Following the rule established by botanists, we support the authority of the earliest nomenclature, and we also invite our colleagues to imitate our example and adopt the specific name *excelsa*, in honour of the celebrated traveller Thunberg, who was the first to make us acquainted with this fine species. This would be an act, not merely of gratitude, but of justice.—*Revue Horticole*.

SOLANUM ROBUSTUM.

As a flower garden foliage-plant this is a subject of considerable merit, and one of those most suitable for the climate of our southern counties. It requires a warm, sunny aspect in a position which will be at the same time airy and sheltered from strong winds. It is a Brazilian species with a vigorous much-branching stem more than three feet high, and furnished with very sharp and strong spines and densely-set, long, reddish, viscous hairs. The leaves, which are very large, are of a

Solanum robustum.

rich brown colour on the upper surface and oval-elliptical in form, with eight or nine oval-acute lobes, the upper ones nearly triangular; and the midrib and principal veins, which are of a brown colour, are closely set with spines similar to those on the stem. The flowers are white, with orange stamens, and are borne in unilateral clusters. The berries are round, of a brown colour, and the size of a small cherry.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Worms on Lawns.—In order to get rid of these take up the turf and relay it on an inch of fine coal ashes; if the grass is weakly, spread a thin coating of good fine soil on the ashes before laying the turf down. There will be no fear of the grass burning in dry weather; the wet soil, which induces the worms to make their appearance, will keep the ashes moist and cool. Thorough draining would also remedy the evil, but as the turf would sink over the drains, it would involve as much trouble as relaying. I have several times used ashes for this purpose, and always with success.—JAMES TAPLIN, South Amboy, New Jersey, United States.

***Yucca recurva* as a Town Plant.**—Holly, Box, Aucuba, and the harder and more vigorous kinds of Rhododendrons are generally considered to be the best of all evergreens for cities. We are strongly inclined to think this better than any of them. We have observed it in all stages of growth in London and its suburbs, and everywhere doing well, when well planted in good, deep, and well drained loam. The fact that it is so totally distinct from our ordinary types of garden vegetation of course enhances its value greatly. At first sight one would hardly expect this native of plains baulks always in a golden sun, to prove such a noble plant in our great fog-pested, sunless London.

Cotoneaster for Walls.—Among the plants seldom used for this purpose is the Cotoneaster microphylla, a plant second to few as an evergreen climber for walls and fences of moderate height. We saw it not long ago covering almost the entire front of a porter's rustic lodge, on which it had been trained. The shoots were trained vertically, about four inches apart, and perfectly straight, to a height of ten or twelve feet; while the side shoots having been carefully pinched, looked the neatest of cordons. This is by far the best and most convenient plan of training this plant. The Cotoneaster is generally plentiful about most gardens as a low, semi-trailing shrub, and those who think of using it as a climber may soon make a good start, by taking up as long pieces as they can find, with a bit of root to each; cut in the straggling side shoots, and plant the pieces close together against the wall, and nail up perpendicularly. In this way we have covered six feet of the wall at once.—J. S. W.

Manchurian Niel Rose as a Weeper.—I have a magnificent specimen of this budded on the Dog Rose and trained as a "weeper." It is planted in the open air, and protected from the north and east winds by matting. It has now more than twenty bloom buds, but little foliage. Can you advise me as to the best treatment? I fear none of the buds will come to anything, and the whole strength of the plant seems concentrated in them, and not in making foliage or wood. I have little or no soft water. Is hard water injurious to plants? and, if so, are there any means whereby its hardness may be tempered?—HERBERT MILLINGTON.—[Mr. George Paul, of Cheshunt, to whom your query has been sent, says:—If there are plenty of unbroken eyes left in the shoots upon which the bloom buds are, the better way would be to prune back to one, and let the plant break afresh from the dormant or unshot eyes. Hard water should be exposed twenty-four hours to the atmosphere before it is used. Have two large tubs filled on alternate days, and always use that filled the day previously.]

THE TOWN FLOWERS' PETITION.

We flowers and shrubs in cities pent,
From fields and country places rent
(Without our own or friend's consent),
In desperate condition,
Yet on no wilful outrage bent,
Do humbly here petition.

Whereas, against our silent wills,
With loss of sun and purling rills,
Cooped up in pots, on window sills,
In rickety old boxes,
The cities' breath our beauty kills,
And makes us grey as foxes.

Condemn'd in walls of brick and lime,
In narrow beds of clay and shale,
To open our buds and shed our prime,
We need some kin'd defender;
We pray, oh, let us live our time!
And we are very tender!

Oh, cheat us not of Heaven's dews!
Nor air (however stale) refuse;
God knows 'tis little we can use,
So choked are all our vital parts.
No slightest care will we abuse,
Nor fail in fond requitals.

We'll breathe you delicate perfumes,
We'll glad your eyes with choicest blooms,
But do not shut us up in rooms
Or stunting crowded places;
The sky, in clouds, a light assumes
To us far lovelier faces.

Our sooty and bedraggled fate
(Our ever-green turn chocolate),
Do you ascribe to spite or hate?
No, we are sure you love us;
Yet, half ashamed, we beg to state,
We love the sun above us.

Then treat us in your gentlest ways,
And next unto the sun's own rays,
With beauty's homage, incense-praise,
We ever will caress you,
And to the ending of our days
In grateful silence bless you.

—All the Year Round.

THE LIBRARY.

"THE MOUNTAIN."*

"The Mountain!" How suggestive the word to all who have any experience of travel in an elevated region! It is true there are mountain tracts, like an enormous region of the Rocky Mountains for example, which are as arid as a limekiln; but happily in northern and in temperate countries this is an exception. We know but little of mountains in this country. They are so few and such dwarfs that they give us no more idea of the nobler mountain chains than babies do of men. It is where a whole country is lifted up on the shoulders of a range that one really sees mountain beauty. To grasp and describe such scenes in all their breadth and significance is work for a Ruskin; for us the vegetation is the all-absorbing theme, and it is on the mountain in which the spirit of vegetation has produced the most lovely results. Hot eastern isle, with its Palms and gorgeous Orchids; Brazilian forest, famed everywhere for luxuriant beauty; gorgeous meadows of bulbs at the Cape, or fairest scenes of our gardens, are as nothing compared with the loveliness one sees on many parts of the Alps. The scenes on the flanks of many a great alp have been aptly described as affording the best pictures of Paradise which this earth contains; and the great mountain is not only a home for the lovely alpine flowers, or the thousands of herbaceous plants that blossom on its side, but nearly all the great trees of the earth are mountaineers. The giant trees of California are almost without exception mountaineers. It

is the same away in the southern hemisphere. Mr. Henry Kingsley has lately shown us some of his sketches of various kinds of trees two hundred feet high, growing on the lofty mountains of South Australia, and between these giants and the brilliant gems we call "alpines" what a vast variety of lovely plants scramble over all the vast mountain chains of this mitre of a globe of ours! This is another of the remarkable books written by M.

* The Mountain. From the French of Michelet. By the Translator of "The Bird." With 54 illustrations from designs by Percival Skelton. London and Edinburgh: T. Nelson & Sons.

The Lake of Geneva and surrounding mountains.

Michelet, and published by Messrs. Nelson, beautifully printed, and illustrated in a superb manner. The following on the mountain forests of Europe will sufficiently indicate M. Michelet's mode of dealing with his subject:—

"On the lowermost terrace of the grand amphitheatre of the mountains, bloom the lofty Chestnuts, forming a venerable vestibule to the forest itself. Patriarchs are these, and animated by a strong spirit of kinship. Less ambitious than fertile, the central tree is wide of girth, and though it does not lift its head to any towering height, it flings off, in every direction, five or six sturdy saplings, the happy progeny which compensates it for the wounds it suffers and for the losses it undergoes. Wrinkled and aged as it may be, this parent trunk still flourishes greenly, and rejoices at the sight of its children. The latter cling to it strongly; yea, so strongly that frequently they are soldered to its trunk, and parent and offspring grow strangely intermingled. The Chestnut loves a soil of granite, or of calcareous sand, whose warm radiation it can feel with far extending roots. It does not dread a lava soil, to which it takes while it is still heated, penetrating into its black entrails. On the extinct volcanoes of Auvergne it lodges in the very craters, and even in their yawning mouths, embellishing them with its verdurous youth.

"The real dense forest commences; at a higher level, with the Beech. If the shade cast by its thick foliage is too gloomy, in compensation its aspect is gay and laughing, and bids you trust yourself to its care, penetrate beneath its lofty vault, and ascend with it the mighty mountains. You find it everywhere, from the Apennines to Norway. You meet with this Fagus of Virgil, which sheltered Titurus, in the lands of the North. The vigorous life of the mountain, the healthy existence of its broad cinctures, maintains in friendship two trees of great sociality but widely different character—the Green Beech and the Black Fir. The beech laughs, the fir weeps; it matters not. They come together on the same heights. Sometimes they are found intermingled, but more generally as neighbours. They share the domain between them. The beech grows on the southern side, the fir on the northern, on the sunless slopes, plunging down even into the low damp valley, gloomy with its shroud of mist. It is the great white fir (*Abies pectinata*) I speak of. A giant, attired in two-fold livery of woe, white within and black without. The snow rests on the long sombre wings of its far-stretching and vigorous branches; and if they bend beneath

the weight, and groan in their double grief, it does but increase the solemn character of the tree. Is it an immense phantom? There are moments when one would think so. Bristling at times with icy crystals, it resembles a formidable bird expanding its wings of menace. In the countries of the South men look upon it as funeral, but in the North they love it. On the shores of the Baltic, from the sands of Prussia to the Siberian deserts, it affords a lasting refuge and an enduring consolation. Here it is the saviour and true guardian of the mountain, in whose protection the two great labourers, the fir and the beech, both unite. It is there they achieve their splendid mission, the real and proper function of the forest. You must remember that at great elevations, and in the narrow table-lands, the forest dwindles almost to nothingness; but that at our present stand-point, at the mountain base, or midway up its slopes, it is still of immense extent, and its labour prodigious. This labour is two-fold. First, it receives, arrests, and breaks up the floods from the upper peaks, which would otherwise devastate the mountain. On the other hand, it incessantly enriches its soil and repairs its losses. It accumulates its wealth of dead leaves upon its surface. It fixes its masses of floating matter. Like a powerful organ of aspiration, it arrests on their passage the fogs and the dense mists, and all that in conjunction with them circulates in the thick atmospheric medium. How pleasant it is to walk in the shade of the fir! Always clean and free from obstacle, the ground underneath them affords a noble idea of purity. What can be purer than the air, with its healthful odours? How soothing a sense of tranquillity gradually steals upon you!

"I know not how to define the lively energy which takes possession of us in these higher regions. We lose sight of the great melancholy fir; for the air becomes too cold, its long arms are too great to battle with the convulsions of the upper air. A more robust tree is needed, with short branches, which will not require to bear so heavy a mass of snow—a courageous tree, a mountaineer, gorged with resin, completely penetrated and protected by it! Such is the Picea, that hardy alpine athlete, which struggles upwards to the most inaccessible steeps, and clings to the very edge of the precipices. It dreads nothing but the mists and humidity of the lower grounds. It will face the cold, but it seeks a wholesome air. With its four rows of stoma, it greedily absorbs the sunshine. By climbing upwards, it gets rid of the strong stimulating food of the inferior levels, the exciting influences of the fermented life. It enjoys a purer and loftier stimulus—that of the atmosphere and the light, and, at times, the summons of the Föhn and the electricity of the storm. The Picea does not own the extended wings of the white fir. It sacrifices all extraneous branches, and enriches itself with foliage, which it wraps around every bough, darting and aspiring in every direction, and feeding it with nourishment and strength. All its thought is to rear itself aloft like a pillar, or like the tall mast of a vessel, which, braving to-day the mountain gale, to-morrow shall brave the ocean. These courageous trees lavish no outlay upon themselves—no luxury, no ornament. They have far different cares on the perilous declivities where they climb to the assault. The wind is icy cold, the rock is bare; but still they mount. They stretch abroad, and attach, as best they may, their meagre roots, and with difficulty attain a footing. It is by pressing closely to one another, by drawing up their serrated ranks and legions, that they support themselves, and, at the same time, support the mountain. In the crises of great inundations the mountain, without their assistance, would be lost. It bursts open—it yawns apart; and the furious waters, profiting by these clefts, and enlarging them, ruining and demolishing, pour headlong on their desperate path towards the valley, where the Piceas stand forward to arrest them.

"You might imagine that you heard the mountain exclaiming, 'My children, be firm!' But lo! from above, a monster avalanche of snow, and ice, and rock, poll mell, starts forward with a frightful shock, and comes leaping from point to point. Woo to the Piceas! It is upon them the first fury of this awful tempest falls. They shriek, they crack. One moment engulfed, they have disappeared. Good Heaven, in what condition shall we see them again? Overturned, with their roots in the air, and miserably shattered! Oh, lamentable ruin! However, with their pointed tops they have broken the force of the blow, as was recently remarked in the Pyrenees, near Barèges, where, indeed, the avalanche was something more than a mass of snow. It was a downfall of ice-blocks, which swept away everything. All the Piceas perished, but they saved the valley."

(To be continued).

Ivy.—Mr. Shirley Hibberd, who for some years past has devoted much attention to these, has in the press a volume upon the subject entitled "The Ivy: a Monograph," which, we understand, will be published shortly.

BOOKS RECEIVED.

The Fortnightly Review (Chapman & Hall, London);—*Agricultural Returns of Great Britain* (Eyre & Spottiswoode, London);—*Plants, the Earth, and Minerals*, by George Becker (W. Macintosh, Paternoster Row);—*Facts about Flowers*, by "H. W." (Hamilton & Co., and Simkin & Co., London);—*La Couture du Raisin*, by Charles Ballet (Dufour-Bouquet, Troyes);—*Italy in England: a Practical Treatise on the Cultivation of Choice Fruits, Flowers, &c.* (Houston & Sons, London);—*The Illustrated Book of Poultry*, by L. Wright (Cassell, Petter, & Galpin, London);—*The Fairfield Orchids* (Bradbury, Evans, & Co., London).

GARDEN DESTROYERS.

BIRDS IN GARDENS.

I HAVE read the sixth chapter of Mr. Reynolds Hole's tale, "The Six of Spades," but notwithstanding Miss Susan's special pleading for the birds, I still contend that, where woods and shrubberies abound, some must be killed if any fruits are to be eaten. Bullfinches, for instance, sing divinely, but in many gardens they clear trees and bushes of buds as the sun melts snow. They eat many, and strew the ground broadcast with hundreds more, as if in sheer wantonness. The gardener, who is held responsible for the dessert, cannot afford to accept their full complement of song as a recompence for a poor dessert. It is easy to write, bar out the birds with nets, but almost impossible to do it. I have counted five hundred birds in a garden on a summer morning. Let a hard drought send these perchore to live on fruit, and have it they will by hook or by crook. There is no help for it. They rush headlong at the nets, using their heads as battering rams, and their open mouths as breach-cutters; and in they go. All of us are familiar with their doings inside. They not only eat, they feast and destroy. Unless nets can indeed be made invulnerable, which they seldom are, it is better to dispense with them altogether. Even the presence of nets seems to excite their appetites, and in very spite, if you save your strawberries, the birds will often riddle your green apples, pears, and peaches. No; where birds are in excess, we cannot save our fruit unless we convert our gardens into huge iron cages by covering the fruit with wire netting from wall to wall. Either this, or pop off a few of them with trap or gun, or destroy their eggs. I know this is a sore point in many establishments, and hence I have adverted to it. My sentiment is wholly with Mr. Hole—or rather his admirable creation, Miss Susan; but my sense is with Joseph Grundy; and yet I love the music of the groves.

But the orchestra may be too large for our means. It needs an enormous garden and an exorbitant outlay for netting to keep up a choir of five hundred songsters. And is there no cruelty in barring the birds out from their food with nets? I should like to ask Miss Susan this question: Which is worst for the birds—a sudden passago from song to silence at the end of Joseph Grundy's gun; or the lingering wail of slow and sure starvation within sight and smell of plenty just outside their fruit protectors? Were I a bird, I know which death I should choose. I suppose no one will contend that there is any more harm in killing birds than in destroying an ant or an aphid? In the fostering and perfecting of vegetable life and its produce, we have to deal destruction to many forms of animal life; and when birds threaten to mar or eat up the works of our hands, we are compelled to restrain their mischief and reduce their numbers. I never, however, met a true gardener who had much pleasure in this work, and the birds are tolerably safe in their hands. But for the inordinate care in the preservation of game, and consequent destruction of hawks and all other birds of prey, we should probably never had to interfere to regulate and reduce the number of fruit and seed eating birds, and so rectify the balance of feathered life as to ensure a crop of fruit.

D. T. FISH.

BULLFINCHES.

MR. INGRAM's remarks on bullfinches (see p. 357) exactly accord with my experience in regard to those little depredators, which attack plum and cherry trees just when their buds are expanding. Bullfinches are, however, never plentiful in this locality, some years being quite free from them, and when they do appear, they are only in small families or pairs; but they can do much mischief in a short time amongst buds. A small cultivator in this neighbourhood, who has an orchard of young plum trees, told me that one day, when he was away from home, a little colony of bullfinches nearly destroyed all the blossom-buds on his trees; and, of course, there was an end of the crop for that year. He has since placed a stuffed cat on a tree in the centre of his orchard when the trees are coming into bud; and this thus saved them over since from injury.

The plague of small birds in gardens when they are numerous is very disheartening; for netting all the fruit that are subject to

their depredations is expensive, much more so than the gun tax. Many kinds of small birds, such as the finches and others, earn their salt by destroying insects and the seeds of noxious weeds; but others, as sparrows, blackbirds, and thrushes, require keeping within bounds, when too numerous. Every year we are told by small-bird protectors that if we destroy our small birds too much, our crops will be eaten up by insects, as they are in France. Our British small birds, however, seem to be different in their habits, especially sparrows; for they care very little about insects if they can get anything else in the shape of grain, buds of trees, and young peas to eat.

WILLIAM TILLERY.

WAR WITH INSECTS ON PEACH TREES.

ALL the time I can spare is, at present, spent at the peach wall. I do not believe in being too early at dislodging if insects are plentiful. One can in a few minutes take off buds—useless buds—which if left a day or two longer, would have sheltered thousands of aphides. The tree is not checked to the extent imagined by some; not so much, in fact, as when the leaves get more developed. Shoots which are close to the wall or the old wood, and consequently sheltered, are those chosen by the insects. Most of these shoots are not wanted; why then leave them for the increase of insects? In going over the trees every day, many of the full-grown winged aphides fall victims to squeezes of the finger and thumb. I have, on a fine day, when numbers of these have been darting in and out, taken a fresh painted board, just the length of the width of the wall, and carried it along as close as possible to the trees. The shade of it causes these winged gentlemen to dart out, and they are caught in the paint. Thousands of little snails, not much bigger than a pin's head, yet having voracious appetites, are also caught. They begin to peel the young fruit as soon as the bloom is detached. If these are not killed now, the leaves will soon cover them, and they will escape the eye and continue to disfigure the fruit all the season. The labour of close and frequent inspection of our peach trees at this time is, therefore, not without its reward.—HENRY MILLS, Eves.

THE WEATHER, BUDS, AND BIRDS.

Thus far the weather, with a trifling exception, has been wonderfully fine; yet, singularly enough, as Mr. Ingram points out (p. 357), the buds are not forward. The sun has been, with some few exceptions, conspicuous by his absence. Hence the buds have rested safely inside their thin shells. There is also another reason: the enormous evaporation from wet surfaces has kept the buds cooler than could have been expected; and thus, though the air, upon the whole, has been mild, the buds have grown but little. But the buds of apricots especially, and peaches, though not in the same degree, look thinner than usual, and the birds, singularly enough, seem more ravenous. We generally suppose that birds' food is more plentiful in mild springs than in cold ones, and, consequently, that the buds suffer less from the attacks of birds. But mild winters and springs cut both ways in regard to the ravages of birds. Doubtless, there may be more food, but there are likewise more birds by far to eat it. Severe winters starve bullfinches, chaffinches, and other bud and seed eating birds; but such a one as we have just had kills none, and hence their terrible raids at this season. A short time ago they set upon plum trees, and peaches, and nectarines, on glass walls. Singularly enough, those on both the north and south side of the glass were more forward than any on brick walls. This singled them out for attack, and in a few hours they were well-nigh cleared. These eaten, they attacked the brick walls, and sprinkled the ground with showers of buds, as well as the blossoms of Ribes in the pleasure-grounds.

We have but two remedies, or expedients rather: Pickle the buds with soot, and catch and kill the birds. We do both to a considerable extent, and the battle rages between some thousands of birds on the one side, and angry gardeners, robbed of their fruit in all stages, from the bud to the table, on the other. To those who, like us, are surrounded with woods, and who would like a full basket of fruit in the autumn, I would say, up and at the birds, and dress the buds at once.

D.

HEMP v. CATERPILLARS.

M. AD. SUCR, in a letter to the *Revue Horticole*, recommends the use of hemp for the purpose of destroying caterpillars. He says:—"Many years ago I saw an individual sowing, broadcast, a coarse grey powder on beds of cabbages, which were almost devoured by legions of caterpillars. On inquiry, I found that this was nothing else than the refuse of beaten hemp, and consisted of the fragments of the dried and broken leaves, and particularly of the

crushed seed vessels. In half-an-hour all the caterpillars had fallen down dead, as if suffocated." He then goes on to suggest the sowing of rows of hemp in beds of cabbages, cauliflowers, &c., stating his impression that the odour of the hemp plants would exercise a sufficiently repulsive influence to protect the vegetables from the attacks of the caterpillars, and concludes his letter, by expressing his opinion that watering cabbages, &c., with water in which hemp had been steeped would be attended with equally beneficial results. The subject is deserving of notice, and seems worthy of experiment.

W. M.

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from page 362.)

ON WATERING AND SPRINKLING.

THE questions most frequently asked by the amateur, when commencing to cultivate plants in pots, are these—"How often should these plants be watered?—Every day, or every two or three days?

These are questions which can only be answered with some approach to truth when the particular circumstances of culture, position, &c., are fully known, and even then many other influences may have to be taken into account. The necessity for watering a plant depends very much on the quantity of moisture which is evaporated from the plant itself, and from the soil in which it grows. This varies according to the kind of soil, the size and shape of the vessel in which the plant grows, the special organisation of the plant, its state of health and growth, its position, the season of the year, &c. Taking all these circumstances into consideration, we shall discuss at length the subject of watering, as this is the part of room-culture on which the health of the plants chiefly depends.

River water, free from lime, is the best; where this cannot be had, rain water should be used; or the lime-impregnated river water, or spring water may be placed in an open vessel for some time before it is used, so as to be brought into contact with the air, and some potash may be thrown into it from time to time. One point about which a mistake is often made is the temperature of the water. Usually people employ that which is nearest to hand; but it is a matter of experience that it is injurious to plants to water them with any water the temperature of which is below that of the room in which the plants are cultivated. It is a fact that when cold water is used, the temperature of the earth about the roots is lowered, and this is more hurtful when the plant is in full vegetation. In open-air culture, or in nature, the soil possesses a somewhat higher and more equable temperature than the air, being much less exposed to changes. Hence it is evident that a higher degree of temperature in the soil than that of the surrounding air, is one of the chief conditions for forcing an early growth. It follows from this that plants should never receive water the temperature of which is below that of the room, and if it is somewhat above it it will do no harm. In fact, where the object is to produce an early bloom and a new growth, tepid water should be used several degrees above the temperature of the room.

The quantity of water which plants require varies considerably, according to their nature, as water plants, bog plants, and land plants. Water plants live entirely in the water, rooting at the bottom of standing or flowing water, or floating free on the surface. Bog plants may be divided into those which grow on the margins of water and which are at times submerged, such as Rushes, Calla, Sagittaria, Butomus, &c.; and, next, the bog or moor plants proper, which grow on the turf overlying watery places, and whose crowns are usually dry, while their roots descend into the underlying water (to this class belong Drosera, Pinguicula, &c.); and, lastly, there are plants which grow in ground that is kept constantly moist, as *Stellaria uliginosa*, &c. The third, and by far the most numerous group, are the land plants growing in positions higher than any water, and which depend for their supply on the rains and the nightly dews.

While for the first two groups (the water and bog plants), either a body of water or a low and wet position is necessary, this would be hurtful to the land plants, which require a free

circulation of the air, and would perish in sour, stagnant soil. When land plants are grown in pots or other vessels, whereby their roots are prevented from drawing the natural moisture from the soil, they will, of course, require an artificial supply, which must be adapted to their wants. As the pots in rooms must be placed in saucers for the sake of cleanliness, if they are watered too often, the water will stagnate in the soil, and render it sour, to the injury of the young roots; if, on the other hand, too little water is given, the roots near the surface dry up and wither, and in both cases the plants become weak and sickly.

The unskilful amateur seeks to extricate himself from this dilemma by watering frequently, but in such small quantity that the entire ball is not penetrated, and no water flows through into the saucer. With this kind of watering the soil cannot indeed become sour, but that part of it which is not reached by the water will soon become so dry and hard that no quantity of water will penetrate it, and the consequences to the plants are equally disastrous.—*From the German of Dr. Regel.*

(To be continued.)

FLOWER BASKET FOR VESTIBULES.

INSTEAD of maintaining the decorations of the vestibules of large country houses, and even those of the town, in the cold lifeless style of fitting up, much beauty, gracefulness, and charm might be added by the use of a well-furnished plant-stand in the form of a basket, of which the accompanying is a sketch. It is made of cut wood, gathered together in the centre with a light brace of iron, and is furnished in the inside with a double zinc basin, of which the first part is perforated so as to allow superfluous water to pass off; an iron stem occupies the centre, and two branches to support

Flower Basket for Vestibule.

three vases in artistic earthenware, or, better still, in iron wire tastefully trellised, holding moss in which the plants are placed. Underneath are planted Dracaenas, Caladiums, Begonias, Ferns, Pelargoniums, young Palms, Fuchsias, with a border of Lycopods. A Cissus or a Tropaeolum Lobbianum climbs up the iron stem. The topmost vase contains a Palm or a Yucca, some light Pteris or Nephrolepis, some Commelina zebrina in falling festoons, and the lateral baskets are similarly decorated. The effect of this basket is very pretty and requires but little attention.—*Ed. André, in "L'Illustration Horticole."*

Flowers and Perfumery.—During the flower season over 10,000 persons are employed in the South of France to extract the aroma from various odoriferous materials. Of flowers, the quantities consumed are said to be—orange, 2,000,000 lbs.; rose, 600,000 lbs.; jasmine, 150,000 lbs.; violets, 60,000 lbs.; cassia, 80,000 lbs.; tuberoses, 40,000 lbs. From this great bulk of material are turned out yearly 200,000 lbs. of rose water, and 1,200,000 lbs. of orange-flower water.

THE PROPAGATOR.

GRAFTING THE WALNUT.

As the Walnut is very difficult to graft, we have tried various methods, and have succeeded by means of the same treatment

as that to which the Oak and the Vine show themselves amenable—a graft in the cleft of a fork. It should be done in the spring, just as the sap is beginning to flow, and the buds to swell. The grafts are branches of the previous year, kept alive in a dark place among gravelly sand, which does not become so dry as common earth. The union of the two kinds whose course of growth is unequal should be avoided, the graft being, in every case, of a kind coeval or less advanced in its nature than the stock. It should be from three to six inches in length, and cut at the end into a triangular shape—as in the case of a common graft—and placed in a cleft made by splitting up the stock as far as the centre of the knot formed at the forking of two branches. These branches should be shortened to about ten inches, and the shoots which arise from them pinched as the buds of the graft progress, taking care that the earlier leaves are left to draw up the

Grafting the Walnut.
sap, which they do without starving the graft.—*C. Ballet, in "Bulletin du Cercle Horticole."*

NOTES AND QUESTIONS ON PROPAGATING.

Propagating Aucubas.—I want a considerable number of small plants of Aucuba for use next winter. Can you tell me the best and quickest way of propagating them?—J. B. G.—[The ordinary way is to have stools of Aucuba layered, and to take off the young plants every year; but for quantities, when the wood is half ripe, or perhaps a little more, that is when the leaves are not too tender, cut the branch up into pieces about four or five inches long with a leaf on the top; put them into a cold frame in September, and by this time they will be all rooted; plant them out thickly in a north aspect in May, having first incorporated with the soil plenty of rotten manure. Nurserymen plant them between the rows of tall plants, such as limes, &c.]

Dracemas.—These handsome plants are becoming so much and so deservedly used in the subtropical garden, and in the decoration of the greenhouse and stove, and even of the dwelling-house, that a few words on their propagation can scarcely fail to be useful. At present they are rather scarce and dear, but they are so readily increased that we look forward to a day when they will be as common as bedding plants. At first sight a Dracema does not look a likely subject to increase abundantly from one stem; but if anybody will place a piece of the stem of an old plant on the surface of a tan bed in a stove, he will find that soon from almost every one of its many joints an eye will break forth. The most forward of these may be removed from the stem from time to time, and if inserted in heat will soon strike, the stem being put back again and slightly covered with the tan or cocoa-nut fibre. It will go on furnishing cuttings for a long time. This refers to all the Dracemas, the beautiful crimson-leaved as well as the green kinds.

Grafting Variegated Pelargoniums.—These are so slow of growth that any means which hasten their development are worthy of being generally known. If plants of the strong-growing varieties, such as Punch, are placed in a brisk heat in a frame or pit, or near the glass in a genuinely warm house, during the present month, they will soon begin to make a strong growth; and when this is so, if they are cut back rather short, and properly grafted with the finer kinds of tricoloured Pelargoniums, these will soon unite with them, and afterwards make a stronger growth than if left on their own roots. In fact, the little grafts taken off will by the end of the season be much larger than their parents. The grafted plants will be ready to put out with the other bedding plants, or may be more quickly grown into specimens for conservatory decoration, for which many of them, such as Lady Cullum and Italia Unita, are well suited.

A TROPICAL GARDEN.

We are beginning to take considerable pride in the effects we manage to produce in our semi-tropical gardens as we call them, produced by means of artificially planting out such shrubs or trees as will stand the English climate pretty well during three or four of our treacherous summer months. The general effect thus created is often very pleasing; yet in most of the plants so treated there is nearly always a too perceptible kind of languor about them, that betrays their want of a balmier and more genial atmosphere—an absence of that gush and profuseness, and lavish vigour of growth, which would characterize a similar scene under a real tropical sun. It is true that our green turf, which enjoys the coolness and moisture of the northern climate, furnishes a refinement of foreground which the plants would not be surrounded with in their native clime; but the combination, though pleasing, has yet an artificialness about it that fails to realize to our satisfaction the ardently-sought aspect of true tropical scenery. Let us turn to the effects of really tropical vegetation, even when reduced to the trim neatness of garden purposes, as represented in the present engraving of a garden at Réunion.

Here we at once find ourselves in the full blaze of tropical luxuriance; we are surrounded by great masses of prickly pear and other cacti; giant ferns, slender-stemmed towering palms, and many forms of foliage, the rank luxuriance of which we feel must be the result of intertropical influences. We are compelled to strain the imagination beyond the usual limits of its power when picturing to itself the utmost beauties that can be reached by the very best management of the means at our command in European gardens; for we have to conjure up the presence of such plants as Strelitzias growing rankly in the open air, and great clinging parasites streaming all over with long racemes of gorgeous flowers, which are hanging abundantly, on all sides, and to the branches of Magnolias in full bloom, and as big as oaks. All this wild profusion of rank vegetable life receives

a chastening and piquant refinement from the European architecture with which it is associated in the annexed engraving, the pure, classical lines of which form a sharp and incisive contrast to the irregular and fantastic profusion of the noble leaf-forms with which it is associated. Gothic architecture, with its elaborate ornamentation, its pointed arches, and its intricate tracery, would be like a repetition of the scene itself, in its tangled and unchecked license of wild-gushing growth, and intricate intersections of lines and forms. It would seem as though a portion of the scene had become petrified, and then

pared down a little to suit human convenience. There would be no well defined line of distinction between nature and art. The European Gothic, in fact, is not suited to tropical scenery, which, on the contrary, harmonises and yet contrasts so well with the simpler Palladian forms of architecture. But while asserting that forms of European Gothic do not contrast successfully with the luxuriance of tropical vegetation, it must be admitted that the characteristics of Hindoo architecture, though allied to the Gothic, and especially to its pointed arches, are exceedingly well suited to contrast successfully with the vegetation of India, even to the rival arcades and leaf-fretted roofs of the vegetable temples formed by the Banyan; and the reason is not far to seek. The pointed arch is, in fact, almost the only link of affinity between Hindoo and Gothic architecture. In the Hindoo style the main lines are horizontal, even to the upper line of all; the whole mass being, in the

A Garden in the Tropics.

main, square, and only varied by a central dome, or dwarf minaret at the angles. It has nothing of the acuminating characteristics of the Gothic, which always seems struggling into a steeple, just as the great bulk of all vegetable forms taper upwards, and therefore offers no reposeful contrast to the surrounding natural features. The native architecture has another advantage over the Gothic as a contrast. Its walls are not profusely perforated with windows; and their smooth expanses (though often delicately chequered with damask-like carving in low relief) form agreeably large, even, and

symmetrical spaces for the eye to rest upon after it is sated with the tangled variety and profusion of over-luxuriant vegetation. It is thus sought to show that in architecture the peculiarities of European Gothic cannot be successfully introduced among the scenery of the tropics, but that the pseudo-classic of the Palladian school, or the various forms of the native Indian styles, are much more suitable as a contrast to the general characteristics of tropical scenery, either in Asia or America.

NOEL HUMPHREYS.

GARDENING FOR APRIL.

THE INDOOR GARDEN.

BY T. BAINES, SOUTHGATE.

Conservatory.—At no time of the year should conservatories be better furnished with flowering plants than at present; nor is there a time when they should be more interesting, on account of the numbers and diversity of plants that can be had in bloom during this month. In addition to the last batch of Hyacinths, Tulips, Narcissus, and other bulbs, there will be forced Hydrangeas, Roscs, Deutzias, double flowering Plums, Spirreas, Lilacs, Epacries, Cytisus, Azalcas, Cyclamens, Cinerarias, and Primulas. These afford so much variety as to admit of the most effective grouping, if tastefully arranged along with such foliage plants as are indispensable, such as Agaves, Yuccas, Dasylirions, Cordylines, Rhipsalas, and Tree Ferns. Without these, whatever numbers and variety of blooming plants may be at command, the general effect will be unsatisfactory. Never crowd, even if more plants are at hand than are required, as it has a most injurious effect. The object should be to grow every plant, even the commonest, so that it will bear looking at individually. Attend well to Fuchsias, Geraniums, and Calceolarias, as these will be required to play a conspicuous part when early spring plants are over. Keep Fuchsias well stopped in, and encouraged with manure water as soon as their pots are filled with roots. Be careful not to use it too strong, however, as when that is the case it does more harm than good. In tying Geraniums, use just sufficient sticks to support them and no more; as soon as their flowers are formed, give them weak manure water once or twice a week. Yet be careful never to give Geraniums too much water at any time, as they cannot bear nearly so much as many things. When Achimenes have made six inches of growth, pinch out their points, to induce them to break and grow stocky, and tie them out sufficiently open to allow the light to act on their bottom leaves, otherwise these will turn yellow and drop off. It is time now to make provision for next autumn and winter's display, by making a sowing of Primula and Cineraria seed; also by striking a batch of Euphorbia jacquiniifolia, Hydrangeas, and Poinsettias. Some experience difficulty in striking this Euphorbia; if the young shoots are taken off with a heel when from four to six inches long, and inserted in silver sand, in a moderate heat, and covered with a bell glass, very few will fail; but if the cuttings are made from a joint in the ordinary way, the greater number will not succeed. Give attention to such plants as Deutzias, Spirreas, and similar things that have been forced; for if neglected now they will not flower satisfactorily next winter. It is the best practice to cut all the old wood out of the Deutzias, depending on young shoots from the base of the plant for next year's bloom.

Stove.—Increase the temperature here, now that the days are getting longer, as the plants will benefit thereby; 70° by day in dull weather, with a rise of 10° when sunny, 65° to 70° at night, will be found about the right temperature. Allamandas, Clerodendrons, Stephanotis, and other free-growing plants that have not been repotted, will require the assistance of manure water as soon as active growth commences. Inure all the occupants to as much sun as they will bear without scorching. There are few plants more worthy of a place even in the most select collections than Pitcher Plants. Many imagine they are difficult to grow, yet such is not the case. Thoroughly open porous material, with a liberal supply of water at the roots *every day*, and plenty of light without direct sun, are what they require. They make few roots compared with most plants, and those they do make are very brittle, and in appearance seem to have little life in them, yet they require the greatest care in repotting, so as not to injure them, otherwise it takes them a long time to recover. This is an uncaring guide as applied to plants in general, those that make few roots are most impatient of having them injured, even ever so little; on the other hand those that root freely soon recover any injury they receive in this way. Attend regularly to the training of climbers, either such as are grown permanently on the roof, or on trellises; if allowed to run too long they are certain to be injured, more especially such things

as Dipladenias and Stephanotis. In lofty stoves, nothing has a better effect than a few plants grown in hanging baskets. For these nothing is more suitable than Hoya bella and Paxtoni, with the different varieties of *Æschynanthus*, *Impatiens*, *Jerdonia*, and similar dwarf-growing plants. Use strong galvanized wire baskets, lined with living sphagnum, inside which place wide shallow pots to hold the plants, using for soil good fibrous peat, with a moderate admixture of sand. The increase of temperature will cause a corresponding increase in regard to the different insects that infest the stove, and which multiply at this season amazingly. These must receive no quarter; choose dull weather, or early in the mornings before the temperature of the stove gets too hot, for attacking them; it is nothing short of cruelty to keep men at this work during the heat of the day, as we frequently see done.

Fern House.—The plants here ought by this time to be growing apace. Keep the atmosphere sufficiently humid for them, but not too close, otherwise the plants get so tender as to be useless, and cannot bear the necessary fumigation to keep down insects. Fumigate often moderately, in place of seldom severely. Do not syringe overhead, as it has a tendency to induce weak growth. Water liberally, as any omission in this respect during the season of active growth is detrimental to the well-being of the plants. The disuse of the syringe does not of course apply to the Flimy ferns, as these delight in water applied overhead, with an atmosphere approaching saturation, and dense shade. Ferns collectively are shade-loving plants; yet there is a great difference amongst them as to their requirements in this respect, which the observant cultivator will note, and act on accordingly, by placing those that require the most shade somewhat under such as will bear more light; by such means the necessity of using too thick shading material is avoided.

Orchids.—Aerides, Saccolabiums, Cattleyas, Laelias, Dendrobiums, with many others, will now be throwing up flower spikes apace, and some vigilance will be necessary to guard against the attacks of slugs and beetles, which are extremely fond of the tender young stems. Many use cotton wool as a means of protection, but it is unsightly, as well as uncertain, as a preventive. It is better to destroy these marauders than attempt to fence them out. There are many traps to entice them to destruction, such as treacle and water, olive oil, placed in shallow-glazed pots. Numbers may be destroyed in this way. Yet I have found nothing equal to Rot & Ringeson's beetle poison. It must, however, be used with care, as I believe domestic animals will take it. Much has been said of late years about the temperature in which Orchids from the different quarters of the globe succeed best. Some argue that all are grown too hot, others that many of the section known as Mexican plants require very little artificial heat, even during their season of growth. A medium course betwixt these extremes will be found the most satisfactory; always bearing in mind that the more light the plants receive, the more heat and moisture they will stand without injury. After long and careful observation I have come to the conclusion that the majority of growers keep their plants too far from the glass, and use too thick material for shading.

Hard-wooded Plants.—Plants that have been potted recently will require close attention in respect to water. It is much more difficult to determine the condition of the soil as to its requirements in this respect with plants that have been recently potted, than with such as are established. All the stock should be gone over every day, and it is quite as necessary to use water that is something near the temperature of the house the plants are grown in as it is in the case of stove plants. Every plant house ought to be provided with a tank sufficiently large to hold a supply of water for one day at least. This is all the more necessary where spring water is used. The larger-sized plants that are required for blooming later on ought, if possible, to be separated from the smaller stock, to give an opportunity of keeping the latter closer with a little moisture in the atmosphere, easily obtained by syringing in the afternoon in bright weather the paths, stages, and outsides of the pots; shutting up the house an hour or two before the sun is off the glass; this must be accompanied, except in the case of newly-potted plants, with all the light available, and more air, otherwise weak attenuated growth will be the result. It is not good practice to syringe overhead, even during the season of active growth, any varieties of plants that are subject to mildew, for it has a tendency to increase the evil. Such plants as are not subject to its attacks, or that are liable to the ravages of red spider, ought to have the syringe drawn over them lightly, every evening after a sunny day, during their growing season. This will apply to Pimeleas, Chorozemas, Eriostemons, Gompholobiums, Acrophyllium venosum, Polygalas, &c. It frequently happens that a vigorous plant will throw up one or more strong shoots that have a tendency to impoverish the rest of the plant; these should be stopped in time by pinching their points out, or bending down so

as to force the sap into the weaker branches; if such shoots are allowed to run unchecked, it becomes a waste of strength, for they ultimately have to be cut back, after having robbed the weaker branches. Heaths are air-loving plants, but avoid admitting it directly upon the plants during the time of cutting winds, or very great mischief will be done to the foliage.

THE FLOWER GARDEN.

BY GEORGE WESTLAND, WITNEY COURT.

THERE are several kinds of evergreens that may now be transplanted when the sap is in motion with the greatest certainty, and amongst them I would particularly mention the Cedar of Lebanon, the planting of which during winter is attended with great danger, whereas, if planted now, the chances of failure are reduced to a minimum. Careful removal is necessary, however, and it should be done speedily, so as to expose the roots to the drying influence of the weather as little as possible. When the tree is in position, cover the roots with the finer portions of the soil, and tread it solidly down, giving a thorough soaking of water, which must be allowed to subside previously to filling up the pit. Mingle the ground above the roots, and little after attention will be necessary. Hollies may also be transplanted at any time during the spring months, a point worth knowing, for the best gold and silver kinds are unsurpassed by any other subjects for summer embellishment. The same remarks are applicable to Rhododendrons and many other evergreen shrubs. Recently planted trees and shrubs must have timely attention, in order to prevent their suffering from want of water, and from wind waving. In the case of large trees, indeed, staking is an important point.

Replant Cerastium and other hardy edging plants. Violets, as they cease flowering, should be lifted, parted, and replanted in ground that is in good condition. Fresh turfy loam and dung, forked into the soil where they are to grow, will be found to suit them perfectly. They delight in a situation shaded from direct sunshine, such as the north side of a wall or in the shade of trees; but avoid "drawing" them by planting them under the spread of the branches. The best varieties for garden display are the Czar, the finest of all single Russian kinds, and the white sort called compacta. Pansies and Violas may now be planted out into beds that are well enriched with manure, and to which fresh soil has been added; bearing in mind that perfect success is only attained by promoting continuity of growth. Sow seeds of hardy annuals, biennials, and perennials, and plant out Hollyhocks. In the case of *Enothera macrocarpa*, part the roots. This showy sort may be propagated in heat by means of the young shoots. Among Oxalis, which should now be divided, corniculata rubra is a very pretty variety for carpet-bedding. The striped grass, *Dactylis glomerata variegata*, should now be propagated by parting the roots. This elegant grass, which is very effective, is not nearly so extensively grown as it deserves to be. Of the Pyrethrum well known as Golden Feather, a sowing should be made at once, upon a warm sheltered border. It will come in well for pannels, where the plants cannot well be too small when planted out.

Unoccupied beds should be treated in accordance to the crop they are to carry. In the case of Geraniums, a dressing of fresh soil will be more conducive to effect than one of rich manure, as over-luxuriant production of foliage proportionately diminishes the amount of flower; while, on the other hand, if an exuberance of leafage is desired, an abundant supply of nourishment must be given. Deep cultivation is important, for except that is secured, no after management will compensate for its loss. Leaf mould and thoroughly decomposed manure should only be used, avoiding rank dung.

General ground work must be proceeded with, and arrears of every description pushed forward. Cut box edgings, and if any remain to be relaid, they must now be seen to. Mowing, rolling, and clipping the edgings of walks will now demand attention. Weeds must be kept under, and perfect neatness and order must be everywhere maintained.

Pits and Frames.—To these particular attention must now be directed, in order to secure as soon as possible the requisite number of plants for bedding out. The harder kinds, that are well established, if the weather is mild, may now be placed under temporary protection to make room for more tender occupants. Turf pits or skeleton frames of wood suit them perfectly, breaking to a great extent cold cutting winds. Plunge the pots in spent tan, leaf-soil, or other light material that may be at hand; this will not only preserve the roots, but save a vast amount of labour in watering. Gradually insure the plants to the atmosphere, and have covering at hand to protect them from frost and to ward off any sudden changes of temperature. Pot off cuttings, and plant out seedlings when fit for handling into frames or boxes. Several of the fibrous root plants may be planted out into frames with advantage, as they lift

safely with balls, and save time in watering. Canna roots should now be divided. There is no necessity for starting them in heat, as they will acquire a sufficient size and plant out better if started in cold frames in a light soil. By this means a more rigid growth is secured. Proceed with the propagation of tender plants that are required in quantities. Sow Asters, Stocks, Zinnias, and other half-hardy and hardy annuals.

THE ROSE GARDEN.

BY GEORGE PAUL.

THOSE who pruned their Roses early in March will, where the plants were thoroughly cut back, find them much in the same condition now as then. Owing to the late inclement weather, while pruned Roses seem hardly to have moved, unpruned plants have grown considerably, in the earlier warm time shooting fully out. These shoots have since been doubtless cut off to the exhaustion of the plants, so that early March pruning has this year answered best. The past frost seems to have injured what few of last year's buds had begun to vegetate. It is difficult to advise, but when much injured (the blackness of the shoot deciding this), it would be well to pinch the injured shoot right back, and, if in health, the plant will push out from the minor eyes which are often found on each side of the leading eye. With the soil in its present condition nothing further can be done; when drier, break down the dug ground with a strong hoe, to form a good tilth. Keep the soil loose throughout the spring and summer with deep hoeing. Climbing Roses on south walls, where forward enough, are worth shading; if a warm, genial time succeeds this, favourable for early flowers, they may produce a supply, say of Glorie de Dijon and Maréchal Niel, blooms very welcome in May and early June. Any pruning left uncompleted should be now done; the eight or nine weeks which bring us into June are but sufficient to allow for a slow, steady growth. If any beds of Roses on their own roots are to be planted in May, it would be well to ridge up the ground (digging in the manure) to get a loose tilth, in which to plant; but out of doors this is a month of rest—to wait is perhaps the grower's most difficult task. Roses in pots started in January will now be fit for tying; they should have been framed when pruned, and the shoots being now two to six inches long, each requires a stick to lead it in a right direction; this will thin out the shoots, admitting air, and, by bending down the leading shoots a little, give a better chance to the secondary ones, and so regulate the growth. In tying, all plants require some slight facing; the shoots, if any without bloom, should be tied back, to thicken the plant behind. A temperature of 55° to 60° in the day; 45° to 50° in the night, as much air as possible, a thorough look out for mildew, and on its detection dusting the spot and sulphurising the pipes, a careful search for maggots, which eat out the buds, are all minutiae which, attended to, insure success in the growth of pot Roses. As a stimulant cow manure diluted with water is safe and effective.

THE FRUIT GARDEN.

BY WILLIAM TILLERY, WELBECK.

Outdoor Fruits.—During these last few days winter has set in with some rigour. At this date, March 23rd, the ground is covered with three inches of snow, and 6° of frost were registered here in the morning. I am afraid that gooseberries and currants, now in full leaf, and some showing their flowers, will be injured. Some of the pears, too, on quince stocks are in flower, and will likewise suffer; but pear blossoms are often injured by severe spring frosts when the bud is expanding. Peaches and Nectarines on walls will now want protection of some kind; for the snow and heavy hail showers that have been experienced during these last few days are worse for the blossoms than dry frosts, that often occur in spring. As soon as the trees are forward enough, disbudding will require attention, removing only a few of the strongest shoots at a time. Bullfinches will now be destructive to plum-tree buds. The best plan to get rid of these little predators is, harsh as it may appear, to shoot them at once. Newly-planted fruit trees will be much benefited by having their roots mulched, should a dry, warm time set in. About the end of the month cut down the shoots of the double-bearing raspberry to within a few inches of the ground. Weed, and lightly fork strawberry beds, if not already done; and if some litter is now placed round the plants, it will keep the fruit clean, and be a protection to the roots in dry weather.

Orchard-House Fruit Trees.—Peaches, Nectarines, Plums, and cherries will now be in full bloom, and plenty of air must be given them on all favourable occasions. See that the soil in the pots is kept moist, but not soddened, for the trees often drop their fruit when young under any excess of moisture or dryness. It is a good

plan to retard a few dozens of these kinds of fruit trees in pots, as they will flower later, and furnish a succession of fruit.

Vineries.—As soon as the grapes in the early houses begin to show colour a drier atmosphere may be maintained, and air given liberally. Water freely the inside borders of the succession houses, and see that the protecting materials on outside borders still maintain their efficiency. Owing to the winter being mild and open, the buds of the vines in the latest houses will be swelling; and in the beginning of the month fire heat, where available, should be applied, so as to get the grapes ripe in September; they will then keep far better than when ripened in October or November. This is one of the great advantages belonging to the plan of bottling late grapes; for the vines can then be properly dressed, and forced earlier. This year I cut the last of our Muscat grapes on the 20th of March, the berries being quite plump, and maintaining, in a great degree, their perfumed flavour. The best coloured and ripened bunches were those that kept the longest and best in the bottles, and this will be found to hold good with other grapes as well as Muscats. I never kept Muscats in good condition much longer than the end of January when hanging on the vines; therefore, I am bound to prefer the bottling system. I find that the best preventive of vine mildew in late vineries is to use some fire heat in dull, moist weather in the daytime, and to give air freely at the same time.

Peach Houses.—The earliest house of Peaches and Nectarines will now be nearly past the stoning process, when a rapid change takes place in the swelling of the fruit; but, before this takes place, it must be thinned if too thickly set, as no more will drop off. If the trees are in good health, the fruit on them may be regulated from six to eight inches apart at this last thinning. When it begins to colour, air may be given freely, and the temperature may rise to 75° or 80° by sun heat. Succession houses will want syringing daily, and attention must be paid to watering the inside border; for, although the surface may look moist underneath, they may be as dry as dust. Tying down the shoots as they progress, and thinning them gradually where not wanted, keeping aphides and red spider in check, will be routine work now for some time in the late houses.

Figs.—Keep these well watered and syringed daily, as red spider is a great pest to them. When the fruit begins to ripen, watering must be gradually discontinued. Stop all shoots when six or eight inches long, in order to encourage a second crop.

Cherry House.—The earliest forced Cherries will now bear a higher temperature; but plenty of air must be given in the daytime, to colour, and give flavour to the fruit. The supply of water at the roots must likewise be lessened for that purpose.

Cucumbers and Melons.—Plenty of heat, together with light, air, and moisture, will now be required for Cucumber and Melon plants, and the shoots must be regulated frequently, by stopping and pruning them, so as not to get too crowded. A steady bottom heat must be maintained to Melons till they flower, and after plenty of fruit is set, liberal supplies of tepid water may be given to the roots. Sow good batches of seeds of both Cucumbers and Melons for a late supply of plants, and some of the ridge variety of Cucumber for planting out in the open air.

Strawberries.—Where plenty of room can be had in frames or in low pits, the remaining batches of Strawberries in pots may now be put in them to flower, and then be taken into the forcing houses as required for succession. By keeping a few dozens of pots of British Queen, Dr. Hogg, and Lucas, in low pits, to furnish the last supply of forced fruit, I have often had larger and finer coloured fruit in the end of June than any grown in the open air during the strawberry season. This was done, by thinning the fruit to two or three on a stem, and using weak liquid manure to water them with. President at the present time with me is very fine, and the fruit stands carriage well, a point of importance to such as have to send it to a distance. Sir J. Paxton, Empress Eugenie, and Eclipse, will follow in succession; and British Queen, Dr. Hogg, Lucas, and Dr. Radcliffe, in May and June.

THE PINERY.

BY JAMES BARNES.

INCREASE heat, humidity, and liquid manure as the light increases and the days lengthen. Carefully tie up to neat stakes all swelling fruits, in order that their crowns may be upright and in natural shape. Shift on strong succession plants, and fill up all vacancies with well-established plants ready to start into fruit. As fast as the fruit is cut, the only way to follow up well at all seasons is to keep in hand a good and certain succession of fruit every day in the year. Continue always to take off suckers, and to pot them as previously directed, in order to have a good succession to select from, for without a methodical and systematic mode of procedure throughout the year, but uncertain success will attend the cultivation of this the king of fruits.

THE KITCHEN GARDEN.

BY JAMES BARNES.

A GOLDEN rule to be kept in mind in reference to the kitchen garden is, to sow little, often, and thin. Thin out and otherwise attend to all growing crops. Trench every bit of ground as soon as it becomes vacant, casting it up rough and in ridges with a strong steel fork. Where necessary, give it a good dressing with manure or other compost, thoroughly incorporating it with the soil, as the trenching progresses. Care must, however, be taken not to bring up too large a quantity of the subsoil to the surface; but it is of great importance to loosen it well every time at the bottom of the trenches. This allows water to run through it freely, and renders it pervious to air, which is so essential to the maintenance of a healthy tilth. During mild showery weather slugs are sure to be troublesome, devouring, as they do, young vegetables, especially those in seed-beds. To prevent their ravages, sprinkle with fresh air-slacked lime. At this season saw-flies deposit their eggs on the young leaves of gooseberries and currants, and by and bye the caterpillars from these prove destructive to the crop. These may be effectually got rid of by immediately applying a thick dusting of air-slacked lime, dry soot, and dry wood ashes, on a mild morning when the bushes are moist with dew, or after rain, or failing the occurrence of moisture naturally, they may be damped with the garden engine or syringe. In this way not only insects' eggs, but also moss and lichen may be got rid of, and a healthy, robust, dark-green appearance given to the bushes and clean stems. Previous to the last ten days or a fortnight, the weather has been favourable for cropping and seed sowing, and now that "bright days have come again" these operations may be proceeded with. Should gaps appear amongst vegetable crops, they should be filled up from parts that are thickest, carefully preserving the roots and lifting with good balls, with a trowel in each hand. Every kind of crop may be successfully transplanted when in a young state by using hand trowels; even tap-rooted plants, such as carrots, parsnips, beets, parsley, &c., will withstand moving in this way whilst young, whilst pulling or taking up young plants, and dibbling them in with naked roots, will be found to be attended with little success. As soon as young crops appear above ground, run a light hand scarifier or an open-toothed rake across the drills to loosen and break the surface; and as soon as the rows can be distinguished run a narrow Dutch hoe between them, so as to keep down weeds, and maintain an open healthy surface. Crops of all kinds should be thinned as soon as they can be handled, so as to prevent overcrowding.

Globe Artichokes.—From the crowns of these remove all weak suckers; strongly grown ones, intended for new plantations, may also be carefully taken off with a root or piece of the crown and planted in lines, two or three plants a few inches apart being put in together, so as to enable them to have a seakale pot put over them for a while until they have become a little established or sheltered with boughs.

Asparagus.—Those who practice the blanching system should finish the covering of their beds. Plants grown on the level ground plan in single rows, the alleys between which were manured and forked in the autumn, and stirred up with a strong hand scarifier during the dry weather in March, should be kept frequently surface-hoed and freed from weeds. The time has now arrived, if the ground has been brought into proper condition by means of previous deep trenching, heavy manuring, and additions of good surface soil, decomposed vegetable matter, seaweed, &c., for new plantations to be made. For these choose the strongest plants that can be got from the seed-bed when they have made a few inches of growth, and having the ground levelled and in readiness to receive them, mark it off into distances of two feet apart. This may be considered by some to be too close; but my plan is to lift when two years old every alternate row for forcing, thus leaving the permanent lines four feet apart. In planting, stretch the line, and draw deep drills on each side of it, thus leaving a ridge just under the line. Across this ridge place the roots systematically astride, and cover them over from both sides. This is a more natural mode of planting than taking out a notch on one side of the line only, and laying in the roots fan-shaped, as it prevents any undue huddling together of the fibres. Asparagus seed may also now be sown thinly in drills, and, as soon as up, thinned by hoe or hand; using the hoe frequently among the young plants, to stir the surface and keep it open.

Of Broccoli, Brussels Sprouts, Borecole, Savoys, &c., make other sowings, to succeed those made last month, the produce of which, if big enough, should be pricked out a few inches apart.

Coleworts.—Make small sowings of these once a fortnight, in order to keep up succession. Little Pixie, Matchless, and dwarf York are best for this purpose and the London green coleworts.

Cauliflowers.—Earth up those, and cover the surface about the roots with a mulching of short dung or litter; leave, also, a basin round

those that have had over them hand lights, in order to supply them with soakings of manure water. Prick off spring-sown plants, and when fit plant them out in succession in cool shady places. Sow Veitch's Giant in succession for late summer and autumn use; these should be planted in partially shaded places, such as between rows of tall Peas.

Carrots, sow these once a fortnight till the middle of July, in order to have nice young roots throughout the season.

Celery, of this sow a main crop on a slight hotbed, and prick off the plants as soon as they are fit to handle, into a well-pulverised, rich soil, such as a compost of equal parts decayed mulchings, leaf-mould, and half-decayed turfy loam, chopping the whole rather finely, and mixing all well together. Towards the end of the month the plants, which by that time will have become strong, may be pricked out on an open border, using the same compost, or a layer of it laid down to the depth of six or eight inches, on a hard bottom. The latter prevents the roots from penetrating too deeply; they, therefore, can be lifted the more easily, with good balls for transplanting permanently. Protect if necessary, and supply water plentifully.

Chervil, sow this in small quantities once every two or three weeks throughout the summer, on cold north aspects.

Lettuces, sow these in drills; thin, and, if necessary and the weather not too hot, transplant the thinnings.

Onions, thin those in beds or lines, and fill up any vacancies by timely transplanting: hoe and surface stir frequently, in order to maintain a healthy and vigorous growth.

Peas, of these sow tall kinds in succession, and run a wide-toothed rake across the drills of those just coming up; draw little ridges of soil about six or eight inches from the sides of the lines, in order to admit of a mulching of litter being administered, and to retain soakings of water that may be given in dry weather.

Spinach, sow the round kind in succession in cool situations throughout the summer; plant out New Zealand Spinach, and encourage the strong winter kinds by frequent stirrings.

Turnips, sow these in succession in drills in cold moist soil for the next two months.

Tomatoes, harden these off, and prepare for planting them out by the end of the month. Preserve a few plants in small pots, and expose them all summer, in order to obtain from them some short, stubby cuttings, for early fruiting next season. The older Tomatoes are the shorter, jointed and more fruitful they become. This treatment is also applicable to the Cape Gooseberry.

Sweet Basil and Marjoram, sow these in succession; prick off those already up, and grow them on in gentle heat.

Angelica, sow this, for next year's crop, in rows two feet apart. The first lot of stalks should now be ready, and should be looked too before they become too hard and strong.

Herb-ground.—This we too often find in a comparatively dilapidated condition. It should, however, now be neatly trimmed, and any blanks that exist in it should be made up. Borage and Burnet sow, and transplant last year's plants of Fennel. Lift the roots of Horehound, and divide and transplant them. Lift young plants of Hyssop, Lavender, Rue, Savory, &c., and replant them in beds, and put in another lot of cuttings. Sow seed of the common Thyme, and plant out that previously sown. Layer and plant out singly Lemon Thyme and Sage. Make new plantations of Tarragon; removing with a knife the young shoots a little under ground, and preserving to each some rootlets; plant it in rows a foot apart. Mint of various kinds treat as Tarragon, and top-dress the beds an inch or two in depth with rich earth or leaf-mould. Camomile, divide the roots, and transplant in rather moist and shady places. Make new plantations of Tansy, Pennyroyal, Balm, &c.

Mushrooms.—Obtain good manure, fresh from the stables, and incorporate it thoroughly with sound adhesive loam, in sufficient quantity to prevent its heating violently, and thus becoming over dry. It is by imprudent over-heating that so many growers fail in producing mushrooms of firm and useful substance, good flavour, and lasting, as regards crop. The most successful place for growing mushrooms during these next six months is in cold cellars, and other places with north and shady aspects. In such situations they are not so apt to become infested with maggots, as they otherwise would be if occupying a sunnier position; but precautions against these marauders are always necessary. To the surface of the beds now in bearing, and those just showing, if dry and crusty, give a little tepid manure water, manufactured only from the dung of cattle, sheep, or deer. It is seldom mushrooms are required to be grown artificially in the late summer months, when they can be procured from the fields; the last bed or beds should, therefore, now be made, to keep up the supply till then. The great desideratum in a mushroom house is cleanliness, by means of whitewashing the walls, and fumigating with sulphur when no mushrooms are in the move at such time.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

(APRIL 3.)

AMONG the many attractive features of this exhibition none were more conspicuous than a magnificent stageful of Cyclamens, contributed by Mr. Goddard, gardener to Mr. Little, of Twickenham, by Messrs. E. G. Henderson, and by Mr. Clarke of Twickenham. We do not remember to have seen on any previous occasion such noble plants of Cyclamens as those shown by Mr. Little's gardener, the plants bearing hundreds of blooms, standing firmly without support of any kind, and springing from a half spherical carpet of rich foliage fifteen inches through. We had seen so many lovely patches of Cyclamen at the various winter and spring shows this year already, that we imagined the season for such things was almost over. But, notwithstanding they began to bloom in September, and may be had in the condition till the middle of next month. This establishes their claim to be considered what we have often pronounced them to be, the most valuable of winter and spring-flowering plants, dehiscing even Cinerarias and Primulas, which were well-established in our greenhouses long before the Cyclamen. Some years ago one saw half-a-dozen Cyclamen blooms perchance among the gay show of ordinary greenhouse plants. Now the tables are turned, and well-grown Cyclamens are the gayest of the gay. In the various collections shown, the variety of form, as well as of colour, was most interesting. This will, doubtless, soon lead to the existence of lists of named varieties, such as happens with "florist's flowers;" but the Cyclamen is in itself such a lovely flower, that those who raise a good batch of seed will really be as rich in beauty as the most fastidious seekers after perfection could desire to be.

Orcids were furnished in great variety and beauty. A plant of Masdevallia Lindenii, bearing nine brilliant purplish magenta-coloured flowers, was one of the most lovely of cool-house Orchids. This came from Mr. Linden, of Brussels, to whom a cultural commendation was awarded. Masdevallia Veitchii, from Messrs. Veitch, and M. ignea, from Mr. Bull; likewise upheld with credit the surprising variety and beauty possessed by the different species of this fine genus.

The first prize Odontoglossums, a class of Orchids excelled by none in point of delicate beauty, contained O. Phalaenopsis, O. Alexandrae, O. triumphans, O. hystrix, Hallii, and Pescatorei. These came from Mr. Ward, gardener to T. G. Wilkins, Esq., Leyton. Mr. Bull won the second prize, and Mr. Linden the third.

Conspicuous among other Orchids were Phalaenopsis grandiflora, growing admirably on bare wood, from Messrs. Veitch, and a grand plant of P. Schilleriana, from Mr. Williams. Among others, we noticed the exquisite little Cypridium nivale, with charming whitish flowers, and Oncidium sarcodes, a distinct and beautiful species.

From Messrs. Veitch came a pretty Oncidium called O. Cresus, a kind dwarf in habit, and bearing flowers of a yellowish colour, spotted with dark brown. To this a first-class certificate was awarded. Another rare Oncidium, in the way of O. ampliatum, came from the Society's gardens.

An example of Odontoglossum cristatum, literally loaded with flowers, was exhibited by Mr. Ward; and Messrs. Veitch contributed a magnificently-flowered plant of O. Andersonianum, a kind believed to be a natural hybrid between O. Alexandra and O. gloriosum. Natural hybridism in this direction, it may be remarked, does not appear to be a rare thing among Orchids; for Mr. Richards, gardener at Gunnersbury Park, also showed an imported plant in every way like O. Andersonianum, except that it was inferior to Messrs. Veitch's plant in point of beauty.

Trichoglossia suavis, from Mr. Williams, was shown large and well-flowered; and a fine variety of the same, with a reddish throat, was contributed by Messrs. Veitch. A plant of Ada aurantiaca, a compact and desirable cool-house Orchid, was furnished by Messrs. Rollinson.

To Dendrobium pulchellum, a charming basket plant, an extra prize was awarded.

Those beautiful and interesting hardy Orchids, which for several years past have delighted lovers of hardy plants at our flower shows, were again shown in excellent condition by Mr. Needle, gardener to His Royal Highness the Comte de Paris, York House, Twickenham. Thenceforward, nobody need doubt that these plants may be grown with ease in pots. Amongst them, we noticed Ophrys fusca, O. bombylifera, O. lutea, O. manosa, O. speculum, O. tenthredinifera, O. aranifera var., O. ferrim equum, O. apiculata, and O. Bertoiana; also Orchis maculata, O. longirostris, O. papilionacea, and O. quadripunctata.

Grand collections of Roses, consisting of both plants in pots and cut flowers, were exhibited by Messrs. Veitch and Mr. Wm. Paul. To Anthurium Scherzerianum, one plant from Messrs. Veitch, and another from Mr. Wills, extra prizes were awarded. Amaryllises came from Mr. Baxter, gardener to C. Keiser, Esq., Broxbourne, who also showed a collection of seedlings, all promising sorts. A fine collection of Amaryllids was also staged by Messrs. Veitch.

Perhaps the most attractive feature of the show was a gorgeously-bloomed collection of Clematis in pots, from Mr. Noble, of Bagshot. These charming flowers, possessing, as they do, great variety and delicacy of colour, form lovely objects in greenhouses and conservatories in spring and early summer, while for outdoor decoration later in the year they are equally well adapted.

Among Rhododendrons was Countess of Haddington, with great trumpet-shaped white flowers, tinged with pink, also a few other fine Azaleas comprised a pure white kind, with flowers bold and symmetrical, named Beauty of Surrey. This came from Messrs. F. & A.

Smith, of Dulwich, and received a first-class certificate. The charming *Tillandsia Lindeni* was again exhibited by Mr. Williams; also another variety by Mr. Linden, called *Lindenii*, a kind with deep rosy bracts, shorter and broader than in the ordinary *T. Lindeni*.

Echiliorum corallinum, with singular wax-like flowers, was also furnished by Mr. Linden. Several fine Palms, some singular-looking Arads, and many other plants of interest, were shown by Mr. Bull, who received a first-class certificate for *Zalacca edulis*, a graceful-looking and promising Palm. A plant of *Areca Baueri*, that received an extra prize, came from Messrs. Rolllisson.

Amongst hardy plants we remarked the pretty and distinct looking *Iris ibérica*, which is amongst the most curious and beautiful of its class, also the lovely little white *Primula nivalis*, a plant shown by several exhibitors, and a few plants of *P. japonica* just coming into flower.

Collections of Daffodils were shown by Messrs. Barr & Sugden, of Covent Garden, Mr. Masters, of Canterbury, Mr. Rawson, Bromley Common, and Mr. Leeds, of Manchester. In the last collection we noticed several hybrids of distinct character.

Of fruit there was little, but vegetables, especially salading, were well represented. Of Peas, two seedlings were exhibited by M. A. de Biseau, d'Hauteville, Binche, Belgium; one of these, named *Bruno de Biseau*, was of remarkably fine flavour, and was awarded a first-class certificate; the other was too far gone to judge of its merits. A fruit and some foliage of the Chocolate tree, that created no small amount of interest, were sent by Dr. Moore, from the Royal Botanic Gardens, Glasnevin. Cucumbers were very fine, two of them measuring two feet three inches each in length; black spined sorts consisted of Oates' Black Spined and Blue Gown; of white spined kinds, there were Pizzey's Favourite, and Winter Supply; of smooth kinds there were Tender and True, and Telegraph.

Of salad vegetables the following came from Mr. Record, gardener to the Marquis of Salisbury, and Mr. J. Heyper, gardener to C. O. Loddar, Esq., Acton, to both of whom equal first prizes were awarded:—Cucumber—Telegraph; Lettuces—All the Year Round, Grand Admiral, Neapolitan; Endive—Moss curled, Batavia, Green curled; Celery—Veitch's Silver White, William's matched; Red; Beet—Nutting's, Pine-apple, Carter's Perfection; Cress—American, Water, Australian or Golden, Curled; Mustard—Winter, White; Radish—Wood's Early Frame, French Breakfast, Red and White Turnip; Corn salad; Chicory; Tarragon; Onions—Tripoli; Sorrel—French; Chervil—curled; and Parsley—Myatt's Curled.

The small salad materials were clean-looking and well grown, but it need not be added that there is no difficulty in the production of such. The essential elements of a good salad, i.e., Lettuce, Endive, &c., were simply wretched; the Radishes, except in one case, were all too old; of course we should not expect good Lettuces in the open ground at this time of year; but, considering the appliances now in our gardens, we were surprised that better Lettuces were not shown.

A few good heads of Broccoli were exhibited; some heads of Matchless, large and close, were sent by Mr. G. Cooling, of Bath; there were also some heads of Excelior, large, and not unlike the former, but perhaps more closely covered by the leaves, from Messrs. T. Watt & Sons, Northampton. A rather curious kind called Leamington, from Mr. Perkins, was shown, and, judging from one we saw cut open, it appeared to be an improvement on the others; the flower was very white, compact, clean, and closely covered over by several layers of leaves, just as if the flower was produced in the middle of a close-hearted cabbage. This self-protection was represented at the meeting as being as likely to induce rot as protection; but this we hardly imagine will be the case. A plant of finely variegated sprouting Broccoli was sent by Mr. Dancer, of Chiswick. Large specimens of an improved Broad-leaved Dandelion, partly blanched, and producing a great quantity of vigorous-looking leaves, were furnished by Messrs. Stuart & Mein of Kelso.

Mr. Kemp, of Albury Park, sent an example of his grape-preserving rail and stand; and we also noticed another ingenious, yet simple, contrivance for preserving grapes in a similar way after being ent. It consisted of two thin tubes united at the base, in the form of the letter V, filled with water, and suspended by means of a piece of wire attached to the top of each tube, and united above them, so as to be hung over a rail or wire as the case might be. Each tube holds a bunch of grapes, just as if they were in a bottle, and it will be seen that any amount of bunches can thus easily be preserved.

ANOTHER VAST NATIONAL PARK.

WE have recently illustrated and described the noble national park known as the Yosemite Valley, and we observe with great pleasure that it is now sought to preserve another and much larger scene for the Americans, or rather for humanity, for all time. This tract of land is called the Yellowstone Park. The following from the reports to Congress shows that the scheme is likely to succeed:—

"The bill now before Congress has for its object the withdrawal from settlement, occupancy, or sale, under the laws of the United States, a tract of land fifty-five by sixty-five miles, about the sources of the Yellowstone and Missouri Rivers; and to dedicate and set it apart as a great national park or pleasure-ground for the benefit and enjoyment of the people. The entire area within the limits of the proposed reservation is over 6,000 feet in altitude, and the Yellow-

stone Lake, which occupies an area 15 miles by 22 miles, or 330 square miles, is 7,427 feet. The ranges of mountains that hem the valleys in on every side rise to the height of 10,000 feet and 12,000 feet, and are covered with snow all the year. During the months of June, July, and August, the climate is pure and most invigorating, with scarcely any rain or storms of any kind; but the thermometer frequently sinks as low as 26°. There is frost every month of the year. This whole region is in comparatively modern geological times the scene of the most wonderful volcanic activity of any portion of our country. The hot springs and the geysers represent the last stages—the vents or escape-pipes—of these remarkable volcanic manifestations of the internal forces. All these springs are adorned with decorations more beautiful than human art ever conceived, and which have required thousands of years for the cunning hand of nature to form."

"In a few years this region will be a place of resort for all classes of people from all portions of the world. The geysers of Iceland, which have been objects of interest for the scientific men and travellers of the entire world, sink into insignificance in comparison with the hot springs of the Yellowstone and Fire-Hole Basins. As a place of resort for invalids it will not be excelled by any portion of the world."

We trust that the bill referred to may speedily become law.

COVENT GARDEN MARKET.—April 5th.

Flowers.—Besides cut flowers in great variety, amongst which were many charming sprays of Orchids, Stephanotis, White Lilac, Guelder and other Roses, we noticed the following in pots, viz.:—Callas, beautifully bloomed; Hyacinths, Tulips, and Narcissi, still fine, especially the Hyacinths; Solomon's Seal, a plant whose beauty is enhanced by being forced; Lily of the Valley; some nice Amaryllids, Gardenias, Mignonette, Cinerarias, and double and double Zonal Pelargoniums, Spring Heaths, Azaleas, Camellias, Rhododendrons, Acacias, Cytisus, Spires, Tropeolus, Carnations, Fuchsias, Deutzias, double-flowering Stocks, Cyclamen, Chinese Primulas. In addition to these were several plants of Dracaena, both with green and coloured leaves, Begonias, Palms, Ferns in the form of the Maiden-hair, and some of the more graceful kinds of Pteris; also various kinds of Club Mosses, such as *S. apoda*, *Krausiana*, and *Mortensia*; plain and variegated kinds of Box, Aucuba, Thujas, &c. There were likewise a good variety of flowers from the open air, such as Double Red Daisies, Forget-me-Nots, Pansies, Primroses, Anemones, Daffodils, Hepaticas, Eranthis, Violets, Wallflowers, and others.

ANSWERS TO CORRESPONDENTS.*

SEVERAL correspondents having sent letters without any address, and one or two even without any name, initial, or other signature, we beg to say that we can take no notice of any communication without the full name and address of the writer, though not necessarily for publication.

B. A. (Only a form of the Common Primrose)—A. L. (Galvanized wire never hurts fruit trees. The best covered walls we have seen for a long time are those under Mr. Stevenson's charge at Cobham Park, and they are all galvanized.)—HARVEY (*Trillium grandiflorum* will thrive in any shady position)—S. L. V. (*The blue Apennine Anemone*)—Sir T. B. (Through Vilimor, Andrioux, & Co., Quai de la Magistrerie, Paris)—W. (We never heard of a similar case, and shall print your interesting note.)—JAMES ELLIS (Next week.)

EXHIBITION NEXT WEEK: Royal Botanic Society (second spring show), Wednesday, April 10th.

* All questions likely to interest our readers generally are answered in the several various departments.

GARDEN

"This is an art
Which does mend nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

THE SIX OF SPADES.

CHAPTER IX.

With that anxiety which we ever feel that they whom we like should like each the other, I have essayed to describe carefully and faithfully the members of our little congress; and though I am well aware how easy it is to sketch from nature without being natural, I hope that I have conveyed to genial minds, by which I mean minds horticultural, some accurate presentments, as well as some favourable impressions, with regard to my floral friends. Writing with truth and earnestly, I permit myself to enjoy the pleasant confidence that I may have imparted to my readers some of the brotherly regard and affection which occupies my own heart for the hoar head of good Mr. Oldacre; for the bright intelligent face of the bearded Chiswick (you should see him in the uniform of our Volunteers, as straight and as handsome as a standard rose-tree); for the shrewd, thoughtful countenance of Mr. Evans, musing upon soils, and "stopping," and training, with a view to future exhibitions; for the shining jolliness of Grundy; and for the kindly goodness of our worthy Curate. And, having this trust as my encouragement, together with some welcome words of approbation which have reached me from friendly critics, I go on joyously to chronicle our proceedings, and follow up my introduction with a cordial invite that you, my reader, will join us, in imagination and sympathy, as we sit in synod, and will listen leniently to our discursive colleagues.

Be with us, therefore, in those "long nights of winter, when the cold north winds blow;" chair thyself comfortably by our hebdomadal board within the pleasant influence of our glowing fire; charge thy calumet with the soothing weed, and thy crystal with golden wine from "the bright and laughing barley;" while thronged on the tiny clouds above us, that sweet little fairy, Queen Fancy, smiles upon our cheerful convocation; and as she waves her magic wand,—

"Again the garden glows,
And fills the liberal air;"

again our beds and borders (hard-frozen in reality without and hidden by the snow) brighter in their summer sheen; again every greenhouse stage bears its precious freight of loveliness; again we see our exhibition vans drawn up at the garden gate, and borne delicately, as though we carried some sleeping beauty whom we feared to wake, the specimen plants so long, so fondly tended, come forth to witch the world; again we await in anxious suspense, during two hours which seem a fortnight, the departure of the censors, and the opening of the doors; again we draw nigh to our favourites, pretending indifference, and trying to saunter, but painfully eager in our fluttering hearts to know what award has been made to us; again those hearts rise, light and bright as a soap-bubble in the sunshine, as we read the welcome words "first prize," or sink, heavy as an underboiled barm-dumpling, to find that we are not placed; again we hear, victorious, that happy "All right, sir," from our gardener, and, like a schoolboy just informed of a hamper, can scarce forbear to cheer; again, defeated, we entertain for a moment an absurd conviction that the judges are either in league against us or in a state of hopeless intoxication, soon recovering our better mind, and finally feeling all the more likely to bear fruit hereafter, like beaten walnut-trees, or any other tree in fact, since each—

"Sucks kindlier nature from a soil enriched
By its own fallen leaves; and man is made
In heart and spirit from deciduous hopes
And things that seem to perish."

Such are our reflections and remembrances, and very soon, after a few preliminary remarks upon the weather, the news of the great world in general and our little world in particular, we come—

"Like doves about a dovecot, wheeling round
Our central wish, until we settle there,"

to open our hearts concerning them. And it is amusing to note the change that has come over us, now that our tourney is over, and the heavy harness of warfare doffed for the trunk-hose of peace. Can we be the same knights, who, whilome reserved, and cold, and dignified, moved through the serried lists? Can I be that captious florist, who, when dear Mr. Oldacre gave me his "candid opinion," which I pressingly solicited, about my bedding out (only I did not really want him to be candid, except in the sweetmeat sense), and told me that I "had sadly too much Perilla, and that the effect of my design was *hearsey*—"can I be the man in whose disappointed breast a malignant voice was permitted to whisper something about a "superannuated jackass?" Alas, I know myself to be so; and I make feeble amends by a tardy thanksgiving to my mentor, and by an acknowledgment to myself that I deserve flagellation from a robust lateral of Araucaria imbricata. And here is Mr. Evans, in a like spirit of meek magnanimity, acknowledging that his Dahlias were not large enough, whereas when the judges gave them second honours, he designated those functionaries as "three old scarecrows," and expressed a strong belief that they were only competent to grow groundsel for sick canaries. Even Mr. Chiswick is acknowledging a failure with regard to some choice Auriculas, and making to his neighbour the Curate a sort of auricular confession; while wise Mr. Oldacre laughs at us all, well knowing that, when spring and summer come, we shall be just as sensitive, jealous, and contentious as before. "But it's all right" he says, "for you're as honest and earnest in peace as in war, and whether the hand is open for amity or closed for sparring, the heart goes with it. May the best man win!"

Ordinarily, we have no stated subjects for discussion, and we pass from one topic to another, as the occasion prompts. We touch promiscuously upon boilers, flues, and stoves; heating, shading, and ventilating; washing, sulphurating, and fumigating; disbudding, stopping, and pruning; tying, training, and packing; manures, solid and fluid; soils, sands, and peat; tallies, lignous, metallic, vitreous; traps for carwigs, birds, and mice; tiffany, nets, and bunting; knives, saws, and scissors (nothing said about tweezers);—these, with five hundred other matters—for our conversation takes an unlimited range, from a caterpillar to the Crystal Palace—pass rapidly before us, as we sit in conclave, "dreaming the happy hours away."

But for six nights in the year, at Christmastide, we have special subjects for the evening's consideration. Each member of "The Six of Spades" is called upon either to deliver a lecture, tell a story, or sing a song, in his turn. Here is our last programme, and a faithful chronicle of its realization shall be given hereafter in *THE GARDEN* :—

"THE SIX OF SPADES."—SPECIAL MEETINGS.

Date.	Member.	Subject.
1st Evening . . .	THE PRESIDENT . . .	Rosa Bonheur.
2nd Evening . . .	MR. OLDACRE . . .	The Lady Alice.
3rd Evening . . .	MR. CHISWICK . . .	On Bedding Out.
4th Evening . . .	MR. EVANS . . .	Show and Showing.
5th Evening . . .	MR. GRUNDY . . .	Mr. Grundy's Song.
6th Evening . . .	THE CURATE . . .	The Happiness of a Garden.

S. R. H.

(To be continued.)

Change of Habit in a Plant.—*Loranthus macranthus* is one of the most interesting parasites belonging to the New Zealand flora, and is nearly allied to our mistletoe. Originally parasitic on native trees belonging to the orders Violaceæ and Rutaceæ, it appears now to have nearly deserted these in favour of trees introduced since the colonization of the islands by Europeans, especially the hawthorn, plum, peach, and laburnum. The latter tree was only introduced in 1859, and appears now to be one of its most favourite resorts, where it is abundantly visited by the (also introduced) European honey-bee.

NOTES OF THE WEEK.

— It is announced that California has hired a State Tree-Planter at a cost of 15,000 dollars a year and expenses.

— ACCORDING to Mr. Scott, there are now forty thousand hands employed irregularly in the London market gardens. These are engaged in the cultivation of eighteen thousand acres.

— MINTON's famous majolica fountain in the Horticultural Gardens, a relic of the Great Exhibition of 1862, is now in course of dislocation, with a view to its removal to the new museum at Bethnal Green.

— THE severity of the past winter in America may be gathered from the fact that this year, for the first time within the memory of man, Lake Michigan has been frozen over as far as the eye can reach, the ice being from four to eight inches in thickness.

— WE hear from Mont-de-Marsan, that the immense plain situated between Moreceux and Solferino, in the Landes, and which is covered with young Fir trees, is the scene of an extensive fire, which lights up the sky for a distance of many miles.

— In California, a new use has been found for the tules or reed-like vegetation which grows on the swamp lands. It is said to yield from fifty to sixty per cent. of paper pulp, equal to that obtained from cotton.

— PRINCE ARTHUR will visit Liverpool on the 20th of May. On his arrival an address will be presented to him at the Town Hall; a procession will then be formed, and proceed to the New Sefton Park, which the Prince will formally open.

— THE Metropolitan Board of Works is employing labourers in filling up the holes on Hampstead Heath, and has instructed its landscape gardener to employ the necessary labour, and obtain seeds for sowing furze, grass, &c., on such spots as may be considered desirable.

— FROM a recently-published return, we learn that there are in France the enormous number of six millions, thirty-seven thousand, seven hundred, and forty acres devoted to the culture of the grape vine. This, we believe, is more ground than all other nations put together devote to wine making.

— MR. H. P. PATTERSON, San José, California, writes to us respecting a beet grown by Mr. Z. M. Brown, near San José, which weighs 175 pounds, measuring six feet long (tops and roots) and three feet in circumference. It grew within twelve months from seeds, with irrigation, but without manure.

— THE Havre papers announce that that town is about to be transformed. A large boulevard, which will be called "Boulevard Maritime," is to reach the whole length of the shore, from the jetty to the cliffs of Ingouville. A wall to support it will be built on the side of the sea. It promises to be one of the most beautiful promenades known.

— AMONGST work in hand in Rome now is the decoration of the public gardens on the Pincian Hill. This favourite promenade is to be supplied with water from the restored Marcius Aqueduct; the walks and plantations are to be renovated; and new busts of celebrated men added to those set up there by the Government of 1849.

— THE Royal Parks and Gardens Bill has resulted in a compromise. Under the new "rules" meetings are to be permitted in Hyde Park, Battersea Park, Victoria Park, and Regent's Park; and any topic whatever may be freely discussed, subject only to the very reasonable restriction that two discordant meetings may not be held at the same time and upon the same spot.

— WE learn that the Cape has recently been enriched by a large introduction of florists' flowers and bulbs; also that seven large cases of seeds, bulbs, and trees, principally of an economic nature, were received by the early January mail steamer, for disposal by the superintendent of the Botanic Garden. In this importation there was a large number of varieties, new to the Cape, of apples, pears, plums, and cherries, seven new varieties of strawberries and Golden Champion grape vine. Upwards of one hundred new dahlias have also been received.

— A MEETING was held this week in the Birmingham Town Hall, "to petition Parliament against a proposal to construct any line of railway through Sutton Park." On Thursday last, in the House of Commons, Mr. George Dixon, one of the M.P.'s for Birmingham, moved that the consideration of the Wolverhampton, Walsall, and Midland Junction Railway Bill be postponed for six months. The Bill proposes to make a line of railway through the prettiest and

most frequented portion of Sutton Coldfield Park, near Birmingham, which may be described as the Epping Forest of that district. There appears to be no reason, beyond that of additional cost, why the projected line could not be made outside the park.

— THE schedule of the Royal Horticultural Society's great summer exhibition at Birmingham is now ready for distribution. The special prize fund, we observe, has reached £945, a sum still short of the amount required by the local committee. Further donations are therefore urgently solicited. The regulations respecting the exhibition of horticultural buildings, implements, &c., are also now being issued to the public along with the schedule.

— AT the Horticultural Congress at Birmingham, two meetings, we understand, will be held at Aston Park, viz.: on Wednesday and Thursday during the show week, for the discussion of subjects bearing upon horticulture. Each meeting will be opened with a short address. That on the first day by Professor Thistleton Dyer, "On Recent Progress in the Scientific Principles of Horticulture." That on the second by T. Moore, Esq., F.L.S., "On the Recent Progress of Practical Horticulture." The same division of subjects will be followed, as far as possible, in the papers arranged to be read each day. The reading of each paper will be limited to a quarter of an hour, and speeches in discussion to ten minutes. In order to arrange the business of the meetings, it is requested that the papers (or abstracts of them) intended to be read, may be sent to Professor Dyer, Royal Horticultural Society, South Kensington, not later than June 1st. The chair will be taken punctually, each day, at four o'clock p.m.

— A FRENCH horticultural swindler is now practising in New York. The specimens of pears in the front window of his shop were found either to have been raised in a hothouse or made of wax. Large numbers of peach trees were described as producing a peach twenty inches in circumference without stone; but on close examination the trees were found to be dead. A coloured plate of gooseberries of various colours all growing upon the same bush, was shown, the bushes selling for two dollars each. Then there were trees four feet high, which were said to produce strawberries exactly resembling "those" raised on vines. This the proprietor regarded complacently as a great convenience, as it facilitated the gathering of the fruit. For these trees in embryo he charges ten dollars each. If the stories of this Frenchman are to be believed, the ladies are certainly greatly indebted to him, for he says he has obtained that long-sought-for and much-desired flower, the blue moss rose, the "bulbs" for the propagation of which he offers for the modest price of five dollars each.

— THE question of preserving for public use Plumstead Common and Bostal Heath, situate at the south-eastern extremity of the metropolis, having been referred by the district board to the Metropolitan Board of Works, inquiries have been set on foot to ascertain upon what terms the trustees of Queen's College, Oxford, who assume to act as lords of the manor, are disposed to sell their rights over the common. The sum named by the College is £18,000; but the superintending architect of the Board having stated that the rights in question are not worth more than £4,000 or £5,000, as the College is prohibited by a recent judgment from building upon or enclosing a foot of the soil, the Board has refused to entertain that offer. The Parks and Open Spaces Committee has, however, reported upon the expediency of preserving these picturesque places for the benefit of the public, and the Board is under the Act of 1866, a memorial having been presented on the subject to the Enclosure Commissioners.

— FRANCE has the largest number of landed proprietors in the world, the most minute subdivision of land, and at the same time the best existing system of registration. The geodesical chart, or *Cadastre*, as it is called in France, and its accompanying register, shows not only the piece of land belonging to each person, but each kind of land separately, and one holder may of course have parcels of arable, meadow, vine, ozier ground, &c., on each of which he pays a different rate of land tax. In addition to this, every change in proprietorship, and every alteration of boundary between different parcels of land, and every conversion of piece of land, has to be entered in a supplementary register, with references to the original and to the chart. This register contains not only the name, address, &c., of the proprietor of each parcel of land, but the exact measurement—no error larger than two metres in a thousand being permitted—of each of its sides, with its mode of cultivation or application. It is estimated that the cost of a new chart and register would be about nine millions sterling; the original *Cadastre* took nearly forty years to complete, and the smallest time that would suffice for the work, with the number of surveyors at present available, is said to be between twenty and thirty years.—Architect.

THE FLOWER GARDEN.

BEDDING SUCCULENTS.

AFTER the rage for colour only in our flower gardens began, in some measure, to subside, something more permanent and quiet in the way of decorative plants was required for. Many found, from experience, that a heavy shower washed

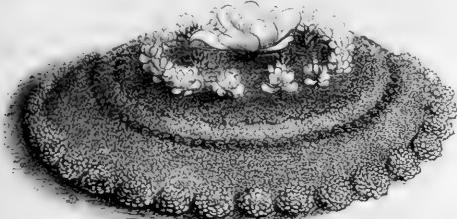

Fig. 1.

away the beauty of their Calceolarias, Pelargoniums, and Verbenas, and that drought often put an end to Lobelias. What, therefore, shall we have next? Our old friends, the Succulents, are not afraid of either sun or rain, and they are easily wintered. Let us have them: but we want variety in the way of growth and colour. A few notes, therefore, concerning such as are best adapted for bedding purposes may be useful.

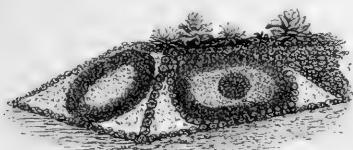

Fig. 2.

For centres of raised beds or for vases, *Agave Verschaffeltii*, *Seemannii*, *americana variegata*, and *mediopicta*, answer perfectly; also *Aloe arborescens*, *fruticosa*, and *succotrina*. For centres of circles, or to diversify a bank, *Gasteria verrucosa*, *Bowieana*, and *candicans*, are all that can be desired. Among tall sorts none are better than *Echeveria metallica*, *metallica glauca*, *gibbiflora*; and among dwarf kinds, *atropurpurea*, *secunda glauca*, *californica*, and *agavoidea*.

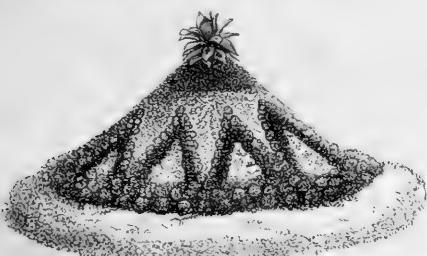

Fig. 3.

As to others, the following are useful as bedding plants, viz.—*Pachyphytum bracteosum*, *roseum*, and others. Tall *Sempervivums* may consist of *arboreum*, *atropurpureum variegatum*, *holochrysum*, and *balsamiferum*. Large yet compact sorts may comprise *canariense*, *urbicum*, *cuneatum*, and *velutinum*. Small kinds, as *Haworthia tabulaeformis* and *aureum*

(*bollii*); and dwarf hardy *Sempervivums* as, *californicum*, *hirtum chrysanthum*, *tectorum*, *soboliferum*, and *montanum*, are always useful.

Among Mesembryanthemums, compact for margins, take *M. fissum*, *Cooperii*, *agninum*, *tigrinum*, *felinum*, *lingueforme*, *bilidum*, *densum*, *hirtum*, *stellatum*, and *marinum*. Those for hanging over vases, or for pegging down, may consist of *M. polyanthum*, *retroflexum*, *rosaceum*, *emarginatum*, *spectabile*, *diexium*, and *aggregatum*. Among white kinds, select *M. blandum* and *curvifolium*. *Kleinia repens* and *tomentosa* are also good white sorts. *Senecio pyramidalis* reaches a height of eighteen inches. *Crassula Cooperii* and *rosularis* are dwarf sorts; and of creeping kinds take *C. marginalis* and *perfissa*.

Among tall *Cotyledons*, the best are *puerulenta* and *elongata*; and among dwarf kinds, *maculata*, *cristata*, and *Cooperii*. Hardy *Sedums* may consist of *S. glaucum*, *hispanicum*, *dasyphyllum*, and *formosum*, among white sorts; *S. reflexum*, *virescens*, and *acre*, green kinds; *S. pulchellum* and *rupestre*, red; and *acre aureum*, yellow. Among *Mammillarias*, there are *spinosissima*, *rosea*, *rose*; *Parkinsonii*, *nivea eximia*, *stellaris*, white; *auriceps*, *sulphurea*, *stella aurata*, and *densa*, yellow. In addition to these, the following will be found useful:—*Echinopsis multiplex* and *Eryresis*; *Cereus strigosus*, *cinerascens*, and *procumbens*.

Among dwarf *Cacti* there are many which might be used; but these are the freest and most easily obtained. Those who like diversity of height may use *Cereus peruvianus*, *glaucus*, and *variabilis*; *Opuntia tunicata*, *leucotricha*, and *horrida*, which grow one, two, and four feet high. *Aloes* and *Gasterias* should be well exposed before being planted out, and they are best plunged in their pots.

Fig. 1.—Centre, *Echeveria metallica*; ground covering, *Sedum* and *Alternanthera*; next, *Echeveria agavoidea*; then *Pachyphytum bracteosum*; circle, *Sempervivum californicum*; margin, *Echeveria glauca*.

Fig. 2.—Top, *Echeveria metallica glauca*, *agavoidea*, *californica*; angular margin, *E. glauca*; circle, *E. secunda*; centre, *Sempervivum tabulaeformae*; ground covering, *Sedum*.

Fig. 3.—Top, *Agave*; ground covering, *Sedum*; margin, *Echeveria secunda*.

J. CROUCHER.

THE DAFFODIL GARDEN.

I HAVE only known two gardens of this kind that seemed in any way perfect, and they contained no variety, only masses of the great yellow Daffodil. Talk of apples of gold in baskets of silver, doubtless they are very beautiful; but the green and gold of Daffodils is even richer and more satisfying. And they rest not day nor night. The merest zephyr stirs leaf and flower like the gentle ripple of the sea.

There stands a pretty dairy at the end of a long walk, which connects it with a ducal kitchen garden. The walk shoots straight as an arrow to its mark, through tall overhanging trees, and hits the dairy in the doorway. But what is that great globe of green and gold in front of the entrance? Seen from under the shade of the wood it looks like a bright cloud or an enormous golden balloon. Why, that is a bed or garden of Daffodils, glowing brightly through the keen, pure air of March!

There is a second Daffodil garden. Across a green lawn, away through glossy hollies, like the walls of green yews, past masses of Rhododendrons lying on the turf, which they have largely overrun, under silver larches, along a walk running round veritable lines of beauty, slipping down valleys and climbing tiny banks, there lies a Daffodil garden, retreating from the eye till its outer boundary is lost amid the green skirts of the overhanging shrubs. It is large, irregular, natural. Its bulbs are planted in large masses in the turf, and the interstices are filled up with common primroses. The leaves and flowers spring forth amid the tender grass, furnishing a niche in the wood far from other flowers, and the surprise and delight which they afford are unbounded. Such groups in gardens of one common plant illustrate in an extraordinary manner the cumulative effect of mere numbers. One—a dozen, a score, a hundred Daffodils may be seen and admired, and almost immediately forgotten; but a waving sea of Daffodils—never. While thus writing of the beauty of the common sort, I must not be understood as disparaging other varieties. On the contrary, I should like to see niches in pleasure-grounds, shrubberies, and woods furnished with them all on a scale of equal width and grandeur. Then, indeed, will our Daffodil gardens become the sweetest and best of features about a place.

D. T. F.

SHRUBBY CALCEOLARIAS.

ACCOUNTS of failures in the growth of shrubby Calceolarias have often surprised me. When I hear complaints made against Calceolarias, or see, as I sometimes do at planting-time, little stunted bits of yellowish green doing duty for them, I feel sure that the plants have been coddled in a greenhouse or starved in small pots. Give them plenty to eat, keep their heads cool, and they will grow like lettuces.

Where bedding plants are grown by the thousand no doubt the best plan is to appropriate a cold frame to the cuttings in the autumn; but I am writing for amateurs, who, like myself, want but about two or three hundred plants at the most, and who cannot set apart a frame for the special treatment of one class only. My plan, therefore, is to insert the cuttings in eight-inch pots about the end of October. Nearly one-half of the pot is filled with drainage, and an open porous soil is used, leaf mould and road sand in the proportion of about two parts of the former to one of the latter being as good as anything. Each pot holds thirty cuttings. When these have been inserted, a thorough watering is given, and the pots are placed, wherever I can find room for them, amongst the chrysanthemums, which at that time occupy my small orchard house. Water is given during the winter only when the pots begin to get dry, and then enough is supplied to make its appearance at the bottom of the pot. Should the weather prove severe, I generally contrive to move the pots to a place where they will be just safe from the frost; at the same time, fire heat is a worse enemy than frost, for in the winter of 1870-71 my pots of cuttings were frozen through for three weeks or more, and I subsequently had no scarcity of plants for my beds.

As there should be a reason for everything, I may as well say that I recommend eight-inch pots, because they hold sufficient soil to keep moist without wanting perpetual watering, so that the plants do not alternate between extremes of wet and dryness; and I take my cuttings late in October, because there is always at that time an unlimited supply of healthy growth to choose from, and no weak shoots are made in winter, as would be the case with cuttings taken earlier in the season. At the end of the year I do not suppose my cuttings have made a single root, but by the end of January the pots are well filled, very few cuttings ever failing. They are then shaken out and planted in wooden boxes at about three inches apart, where they remain (still in the orchard house) until spring weather sets in. They soon make rapid growth, and are from time to time pinched to keep them bushy.

About the first or second week in April, or earlier if the weather appears settled, they are planted at about nine inches apart in a sheltered corner of the garden. Here they receive no further protection, unless frosty nights occur soon after they are put out, in which case they have some tiffany thrown over them. Were not my beds always full of spring flowers at the time, I think it would be better to plant at once in the positions intended to be "occupied in summer." The plants are kept constantly stopped as they make fresh shoots, and by the time they are wanted they are nearly a foot through.

And now as to soil. I have seen a strong soil recommended, but of such I have no experience. I use, both in my boxes and afterwards in the nursery bed, an open and porous soil, or, if I may so describe it, an elastic soil, composed chiefly of decayed leaves, such as one finds ferns revelling in in woods.

The one fault of the Calceolaria, and no doubt the reason of its being in ill-favour with many people is, that it is apt to flower itself out in a hot, dry summer by August, when other bedding plants are at their best. This may be of more consequence to those who "bed out" elaborate patterns than it is to me. Flowers are as valuable to me in June and July as afterwards, and I can excuse plants taking a rest after giving me, for six or eight weeks, a sheet of bloom. I know my Calceolarias will be bright enough again when the autumn rains revive them. This exhaustion may, however, be in a great measure obviated by placing a good layer of half-decayed leaves or manure in the beds, and giving copious supplies of water in hot weather, and if in addition a situation shaded in the hottest part of the day is chosen, and about

half of the first set of blooming shoots are pinched back before flowering there will be little reason to complain of the plants at any season.

I do not think the Calceolaria is suited for places exposed to a blazing sun, though it will stand a good deal if kept cool and moist at the roots. There is no lack of plants which rejoice in such positions. Calceolarias, especially yellow ones, always look best without direct sunlight, and to my mind yellow should be but sparingly used in the full glare of a summer's sun.

W.

A RAMBLE AMONGST BRITISH ORCHIDS.

A YEAR or two ago I was in Buckinghamshire in March, in a neighbourhood abounding in British Orchids. The first I found was the beautiful *Orchis mascula*, there called Ring Fingers. Arleyford Wood contains thousands of them, and myriads of Primroses. I looked amongst them and saw one, a snow white variety of *O. mascula*, which I dug up with as much earth as would adhere to its roots, brought it home, and carefully potted it. The first season it was magnificent, and kept in bloom for six weeks, a much longer period than the usual purple form would have done; indeed, I am not quite certain that it is not a distinct species. One day I was told that Whittington Park was famous for Orchids, so away to it I went, and there I found *O. Morio* in many varieties, from pure white to the richest purple; and in a piece of sandy bog I met with *Epipactis palustris*, *Listera cordata*, and *O. maculata* in many shades of colour, notably a pure white variety. *Orchis maculata* is a fine thing for pots, and is easily cultivated; so are *mascula* and *Morio*. I found also in this bog the beautiful little *Anagallis tenella*, and in the same field *Spiranthes australis*; over the hedge, in a wet place, was a grand lot of *Chrysosplenium oppositifolium*, and nearer *Epipactis purpurata*. In the adjoining wood I came upon a bog containing a fine grove of *Equisetum Telmateia* and *E. sylvaticum*; and in the wettest places, Buckbean. In this wood I also found a variegated form of *Pteris aquilina*; and *Osmunda regalis* grows there, but I did not see it. *Listera ovata* I also found in great quantities, and one plant of it beautifully variegated; and, last of all, such grand plants of *Habenaria bifolia*. Altogether I do not remember any thing that pleased me more than meeting with these floral gems. Masses of the lovely *Pyrola media*, *Epipactis latifolia*, also abound in that neighbourhood.

In respect to cultivation, I have tried the different methods recommended, such as mixing chalk with the soil; but I find this does not suit. I take equal parts of maiden or hazely loam, sandy peat, and leaf mould, not much decayed, plenty of silver sand, and some broken bits of charcoal; I also crock with charcoal. Dig up the plants any time when you can find them with a ball of earth; when they are taken home, carefully remove all the earth you can without injuring the roots, drain well, and pot carefully and firmly. Plunge the pots under a north wall and in clean river sand; supply them liberally with water during the growing season, and in November remove them into a cold frame having a southern aspect, and you will be surprised at the result. They require to be more generously dealt with under artificial treatment than might be imagined from the position and localities in which they are found. *Ophrys apifera*, *O. muscifera*, and *Orchis pyramidalis* are capital sorts for pot culture. *Gymnadenia conopsea* I found on Ashley Hill, also a beautiful white variegated form of *Epipactis latifolia*; and in the Muntz a lovely variegated *Epipactis purpurata*, with the foliage banded and striped with rose colour, much in the same way as *Tredescantia discolor*; this I have unfortunately lost. I find that variegated forms are very common where Orchids abound. *Neottia Nidus-avis* can be cultivated; I do not think it is the root parasite that some observers have stated. If anyone would collect the whole family of British Orchids, and grow them as they are capable of being cultivated, they would form a *tout ensemble* worth a long journey to see. What a grand bog-plant *Orchis latifolia* is! and what is that *Orchis* so much like it, but with larger flowers, denser spikes, that blooms a month or five weeks later, and in a similar situation? I shall strenuously exert myself to bring these and other rare plants into notice, and then, when the public get familiar with them, no place will be complete without its bog garden. Of late years the great improvement in public taste for variety in decorative plants, has given a stimulus to the cultivation of these our native plants; for many are the undiscovered gems we possess, wasting their sweetness on the desert air, where the windflowers dance merrily in the breeze, where the sundew opens its golden eyes in the depths of our grand old woods, and by the side of the langhing rivulets as they leap from the mountains to the valleys. Verily, does not nature sing an everlasting song, and shall not we rejoice in these the lovely children of the wood and wild?

W. ELLIOT.

THE ROSE SECRET.

AFTER all that has been said about striking rose-cuttings as easily as willows, I wonder that none of your correspondents has made mention of striking them in a way pretty nearly the same as I remember to have struck willow-cuttings when a boy. How this may be done is told in the following extract, which I take from a French work, "La Taille du Rosier," by M. Eugène Forney, p. 69:—

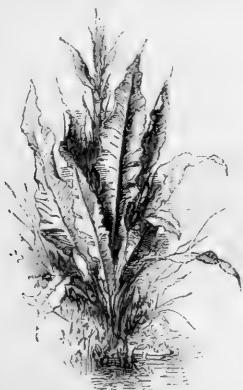

"We are indebted," says the author, "to M. Lucy, of Marseilles, for an ingenious method of striking winter cuttings of the rose, which is easy to perform, and gives perfect results. A piece of stick is laid upon the ground, quite level; on each side of the stick little notches or trenches are taken out with a spade, rose-cuttings of about ten inches in length are made, and bent over the stick, with their two ends lowered into the trenches. The trenches are then filled in with soil, so as to leave only one eye of the cutting upon the top of the stick above ground. It is to be remarked that roots form only at the lower end of the cutting; the other end ultimately withers away up to the young shoot. It is easy to understand that a cutting managed in this way must be certain of success, since its upper extremity, being embedded in the earth, is not subject to dry up in the spring. Hard-wooded kinds, difficult to strike by cuttings, treated in this way, have given excellent results."

I laid after this manner about thirty cuttings of different kinds in October last, and at present they are all in vigorous condition. At the same time I also laid a great number in the ordinary way, and about three weeks ago nearly all seemed flourishing, and likely to succeed. Since then, however, such as were not long and stout, and well buried in the soil, have shown symptoms of dying off, doubtlessly dried up, as M. Forney observes. T. A. C. FIRMINER, Edmonton.

THE GREAT WATER DOCK.

(RUMEX HYDROLATIUM.)

THIS not uncommon native plant is of great value in the picturesque garden; far more so than any exotic we could name as suitable for like positions. It is a very large water-side plant, of a size and habit sufficiently striking to entitle it to a place amongst ornamental subjects by the water-side. The radical long-stalked leaves, which are sometimes two feet

The Great Water Dock.

or more in length, form erect tufts of a very imposing character. The flowering-stem is frequently six feet in height, and bears a very large, dense, pyramidal panicle of a reddish or olive-fawn colour. The plant is most effective in autumn, when the leaves change to a lurid red colour, which they retain for some time. No care whatever is required in its culture. It merely requires a place by the margin of a lake or stream.

FERNs ON THE EASTERN SCOTISH BORDER.

THE following is a list of Ferns to be found around Kelso, and as it is a district often visited by tourists, amongst whom are many Fern collectors, it may be of use in indicating the stations where they are to be found:—

Common Polypody (Polypodium vulgare).—Common on shady banks, rocks, walls, and old trees.

Beech Fern (P. Phegopteris).—Frequent in moist, rocky places on Cheviot and the adjacent hills.

Oak Fern (P. Dryopteris).—This delicate-looking species grows on Cheviot along with the last, also near Hume.

Mountain Parsley (Allosorus crispus).—This elegant Fern is very local in this district; it is plentiful on the west side of Henshaw (a wild glen on Cheviot), also on the Eildon Hills, and Black Hill at Earlston; it appears to like good drainage, as almost every plant I have seen of it is growing amongst loose stones.

Common Prickly Shield-Fern (Polystichum aculeatum).—This and the variety lobatum is not uncommon about Makerston and Melrose.

Mountain Buckler Fern (Lastrea montana).—Plentiful in Bowmont Forest, and the sides of rills on the Cheviots.

Male Fern (Lastrea Filix-mas).—This is the most common species in this quarter, where it varies greatly in appearance, both in form and size.

Broad Buckler Fern (Lastrea dilatata).—This, like the last, is both common and variable; it is most abundant, and thrives best in Scotch fir plantations.

Lady Fern (Athyrium Filix-femina).—This graceful and elegant species is frequently met with all over the Borders; also the variety purpureum. The variety rhacemicum is common on Cheviot; I found a very fine form of rhacemicum in a plantation at Ewart Park, with fronds from four to five feet high.

Forked Spleenwort (Asplenium septentrionale).—This rare little Fern grows on Trap Rocks overhanging the Tweed at Makerston; it appears to delight in sunshine (rather uncommon thing with Ferns, as all the plants I have seen of it face the south).

Alternate Spleenwort (A. germanicum).—This was found at one time near Kelso; but as far as I know it is now extinct.

W. R. F. (A. Rothianum).—Rare about here; but may be found on an old wall near Yetholm, and plentifully on Melrose Abbey and Berwick Walls.

Common Maidenhair Spleenwort (A. Trichomanes).—This is common on rocks and walls about Makerston, Newtonton, Sandyknowe Crags, &c.

Sea Spleenwort (A. marinum).—This handsome evergreen Fern grows sparingly on the coast of Berwickshire; also at Twizel, on the banks of the Till, seven or eight miles from the sea.

Black Maidenhair Spleenwort (A. Adiantum-nigrum).—Found in the same localities along with A. Trichomanes.

Hart's Tongue Fern (Scopelodium vulgare).—This, though common in many parts of the country, is rare here; it grows on the north side of the garden wall at Newtonton.

Hard Fern (Blechnum Spicant).—Common on the hills and moors; it grows very strongly in Bowmont Forest, the fertile fronds being generally upwards of two feet high. I found a plant there with most of the fronds of the normal form, some forked, others the same as in the variety anomalous, and an intermediate form between anomalous and the type, all on one plant.

Bracken (Pteris aquilina).—Abundant on the hills.

Brittle Bladder Fern (Cystopteris fragilis).—This grows luxuriantly at Aichill Linn, and it is plentiful in some of the rocky glens of the Cheviots.

Wilson's Film Fern (Hymenophyllum Wilsoni).—I have a specimen of this moss-like species, obtained from a friend, who got it on the Cheviots, though I have not seen it there myself.

Flowering Fern (Osmunda regalis).—I have heard of two plants of this noble-looking Fern being found in this district, one on Cheviot, and the other on Coldingham Moor. It grows luxuriantly about the canal and damp places in Newtonton Woods, but to these stations it has been introduced.

Moorwort (Botrychium Lunaria).—This is to be found on Cessford Moor, and on the Lammermoors; but it is rare and local.

Common Adder's Tongue (Ophioglossum vulgatum).—Has been found near Melrose.

As the Club mosses are nearly related to Ferns, I may just mention that *Lycopodium clavatum* is common on all our moors; *L. Selago* and *L. alpinum* are also both plentiful on the top of Cheviot.

KELSO.

A. B.

WIGANDIA DISEASE.

I HAVE a plant of Wigandia, one of several attacked by a disease similar, if not identical, with that which attacks the potato. I have seen it in several classes of plants, such as Verbenas, Bouvardias, Pentstemons, Heliotropes, &c., and I have for several years tried many methods to get rid of it. I have applied sulphur alone in a dry and in a moist state, also sulphur and soot, and sulphur, soot, and snuff, as I thought at one time the disease was caused by thrips; but I soon found out that it was not caused by an insect. Then I began to think of my old potato remedy, viz., dusting with lime, which thoroughly answered my expectations.

The disease attacks them in the youngest and most tender part of the stem and leaves. About two months since, I had a plant showing symptoms of the disease, on which I operated, and now it is growing away as clean as it was before the attack. The malady appears almost all at once, that is within twenty-four hours, and attacks the young and tender tops. I find, as in the case of the potato, that it is caused by a sudden change from warm and genial to a cold and damp atmosphere. It also spreads rapidly; and for the future I intend trying lime-dusting on all plants affected that come under my observation.

Wellington Nursery, St. John's Wood.

R. H. BARD.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Iris Kämpferi.—This beautiful little Iris, the varieties of which are so much admired by all who know them, has stood this winter out of doors quite unscathed. Many are not aware that this fine and uncommon plant is hardy.

Palms in Guernsey (see p. 377).—The following have been grown in the open air here for several years past, and do well. They are quite hardy with us, viz.:—*Chamaerops excelsa* and *humilis*, and *Rhapis* *stabiliformis*. *Cordyline australis* and *Banksii* also succeed in the Channel Islands.—JOHN RICH'D. WILLIS.

Single Mauve Primrose.—This beautiful spring flower, sometimes called the Irish Primrose, is now in full bloom in London nurseries, and is a plant worthy of general culture. Another richly-coloured deep magenta single variety, also distinct and beautiful, is likewise in full bloom. These charming early flowers should be seen everywhere, where spring flowers are grown.

Daffodils.—There is a slight error in the interesting notice of Daffodils which appeared in your issue of March 30th (p. 419), respecting the two large varieties distributed by us under the names "The Emperor" and "The Empress." The one with the sulphur perianth was called "The Emperor," whilst the other, with the white perianth, was named "The Empress"—this being exactly the reverse of what was stated by your correspondent JAS. BACKHOUSE & SON.

Myosotis dissitiflora.—This charming early spring bedding plant will not, I fear, stand much frost. I had a nice bed of it here edged with the variegated *Arabis*, and it was in full flower just before the weather changed to its wintry character. Nothing could have looked prettier in the way of a spring bed than it did; but now the flowers look all scorched and dead, and this after two mornings' frosts, on the 22nd and 23rd ult., when 5° and 6° of frost were registered on those days.—WILLIAM TILLERY.

Rock Gardens.—What seeds would answer best to sow in what was formerly a limestone quarry, but which is now prettily planted with trees? The rocks are picturesque.—M.—[You are fortunate in having so good an opportunity of making a noble rock-garden at little cost. The great majority of alpine and dwarf herbaceous plants will thrive well in such a position. To cover the ground and the rock seams, and get a showy bloom soon, you could not do better than begin with all the dwarf bell-flowers (*Campanulas*), and all the good showy cruciferous alpine plants you can get. We allude to the various kinds of perennial rock Candytuft or Iberis, the Alyssums, *Aubrietas*, and *Arabis*, all now easily obtained in nurseries and from seed. Consult "Alpine Flowers" and "The Wild Garden," both of which books deal with such spots as you name.]

THE HOUSEHOLD.

SELECT EDIBLE FUNGI.

THE VEGETABLE BEEFSTEAK (*FISTULINA HEPATICA*).

ALTHOUGH the popular name of "liver-fungus" corresponds very well with the scientific name of this species, yet we consider the name of "Vegetable Beefsteak" (aptly given to it by Dr. Bull, of Hereford) so very much better, both as regards the shape of the fungus itself and its taste, too, that we prefer to keep it here as its popular name. The taste is exceedingly like beefsteak; but it must be confessed, that a well-grown specimen more resembles a great tongue than either a lump of liver or steak; hence it is known in Italy as "*Lingua querina*" or "*Lingua di Castagna*," and in France, "*Langue-de-boeuf*."

This fungus, which resembles a great red tongue protruding from tree-stems, when once known can never be mistaken for any other species. It generally confines itself to old (and often prostrate) oaks; but, in Epping Forest it is not uncommon on the beech. We have also seen it more than once on the ash; and it has been observed on the chestnut, walnut, willow, and other trees. We have tasted it from various habitats, but have never been able to detect the least difference in the flavour. Although

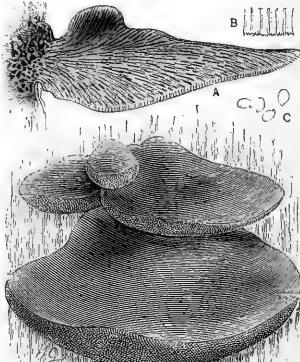

such a large fungus, its growth is very rapid, soon appearing, and again disappearing, on ancient trunks in the autumn.

When cut, broken, or bruised, it distils a copious red juice like beef gravy.

"When grilled," says Dr. Badham, "it is scarcely to be distinguished from broiled meat;" and Berkeley describes it as "one of the best things he ever ate, when prepared by a skilful cook." There is a very slightly acid flavour in the fungus when cooked, which adds considerable piquancy to the dish; it is extremely tender, succulent, and juicy, and resembles tender steak or tongue in a remarkable manner, the juice it distils being in taste and appearance like gravy from an excellent broiled rumpsteak. Of course, it should be gathered when quite young, fresh, and clean, and at once prepared for the table in the following manner:—

Wash and dry, and cut into quarter-inch slices half-an-inch wide, soak in scalding water for five minutes, and stew with butter and herbs; yolk of egg may then be added, and serve hot; or simply stew with a good steak, adding a scallion and parsley, salt, and pepper.

For *Fistulina Ketchup*, slice and macerate with salt, and, says Mrs. Hussey, serve "with a little lemon juice and minced shallots, with a broiled rumpsteak."

BEEFSTEAK FUNGUS (*FISTULINA HEPATICA*).—Upper surface at first pale purplish red, then chocolate; under surface at first cream colour, then yellowish red; height six inches, width, according to species, more or less like beet-root; size, from six inches to two feet in diameter. A. Section through centre. B. Tubes enlarged, showing fimbriated orifices. C. Spores enlarged seven hundred diameters.

Unfortunately there are not many references to fungi in Shakespeare, so that it is extremely difficult to get an apt quotation; but there can be little doubt that Shakespeare was well acquainted with edible fungi, and a certain passage, met with in "As you like it" (Act ii., scene 1, Forest of Arden), if amended as we would suggest, would certainly show that the Bard of Avon was well acquainted with both the habit and edible qualities of *Fistulina hepatica*. The passage we have in view concludes the description of a forest scene, where, no doubt, the *Lingua querina*, or "Tongue of the Oak," bounded.

The lines are, as usually printed:—

"And this our life, exempt from public haunt,
Finds tongues in trees, books in the running brooks,
Scribbled sermons in stones, and good in everything."

Of course, this is so much nonsense; Shakespeare could not have written such lines. Attempts have more than once been made to amend them, but never with any success till now. Without doubt, the following reading is what Shakespeare originally wrote:—

"And this our life, exempt from public-houses,
Finds sermons in books, stones in the running brooks,
Tongues in trees—and good eating!"

And good eating they are—Shakespeare knew it long before Dr. Badham.

W. G. S.

THE LIBRARY.

"THE MOUNTAIN."*

(SECOND NOTICE.)

"THE MOUNTAIN" contains numerous and beautiful illustrations; chiefly of mountain scenery. It is a companion volume to those interesting works "The Bird," and "The Sea," and is devoted to the aspects and life of the mountain and all its children; its lava streams, and its canopies of snow; its torrents, ravines, and forests. It is not technical; though full of pleasant instruction. We do not find so much about alpine flowers as we should like, though most of the subjects connected with mountains are treated of.

To us the Alpine regions seem an earthly paradise; to those who have to live in their terrible wintry solitudes they bear a very different aspect:—

"The mountaineer does not regard his mountain from the same view-point as ourselves. He is strongly attached to it, and constantly returns to it; but he calls it the 'evil country.' The white glassy waters which escape from it, leaping and bounding in furious rapidity, he names 'the wild waters.' The black forest of firs, suspended to the precipices, an image of eternal peace, is his war, his battle. In the roughest months of the year, when all other labour ceases, he attacks the forest. It is an arduous campaign, and full of perils. It is not enough to fell the trees, and start them headlong; their course must be directed. He must watch them on their passage, and regulate the terrible leaps which carry them to the bed of the torrents. The conquered is often fatal to the conqueror; the tree to the woodman. The forest has its mournful histories of orphans and widows. For the wife and the family, a terror full of mourning rests upon yonder heights, whose woods, mingled with snow, mark them out fearfully from afar by spots of white and black. Formerly the glaciers were objects of aversion; men regarded them with eyes askant. Those of Mont Blanc were called in Savoy 'the accursed mountains.' German Switzerland, in its old peasants' legends, doomed the damned to the glaciers. They are a kind of hell. Woo to the avaricious woman—to the hard cold heart which in

Himalayan Mountain Scenery.

winter drives her aged father from the blazing hearth! As a punishment she shall wander, with a hideous black dog, wander without rest in the regions of ice. In the severest nights of winter, when everybody presses close to the charcoal stove, you may see there on high the white woman, faltering and tottering among the sharp-edged crystals. In the diabolical valley, where, every minute, thunders and crashes the avalanche from the summit of the Jungfrau, a host of doomed barons and ferocious knights ever dash and hurtle one against another, and shatter their fronts of iron."

To see the pathways through some high and narrow valley, garnished with frail and rude wooden memorials of those who have perished, is, however, more suggestive of the horror of mountain life in winter than anything to be gleaned from a description. Our illustration shows a scene in the great Indian range, and also the generic affinity which exists between all mighty mountain chains. Differ they may in flowers, forests, and temperature, but the same law everywhere moulds them, and almost everywhere the stately plume of the pine fringes the silent and perennial snows.

"The resinous trees comprehend more than a genus or family; they are a vegetable world, whose various forms record for our behoof the ages which have preceded our human era. Born in the time of the ferns, the cycads, and the equiseta, they continue to imitate them in certain species. For example, the cephala still fashioneth itself upon the equisetum, but by a system of joints attains a greater stature, and instead of foliage is clothed in scales. The resinous giants, such as the araucaria and the sequoia, still astonish the earth as she was astonished in her powerful youth, when her trees were mountains.

"In the southern hemisphere, the life of the resinous trees, which is more concentrated in genial climates, has a very different character.

Set free from the hard task of supporting masses of snow, and enduring the pitiless strokes of the hurricane, they breathe more at ease. The araucaria of Brazil or Chili bears a leaf like that of our tiny holly. The dammaras of Amboyna and New Zealand, reeking with warm waters, may well dilate their lungs. They cast off the thin needle-like form of the conifers, amplify their foliage, and grow in height and girth without restraint.

"The true stoics are our resinous trees of the North. They endure the sharpest trials by their power of self-concentration and their heroic sobriety. It is by such means they have prevailed over both space and time. Useful and beneficent, and greatly profiting the

* The Mountain. From the French of Michelet. By the Translator of "The Bird." With fifty-four illustrations from designs by Percival Skelton. London and Edinburgh: T. Nelson & Sons.

world, they ask from it scarcely anything in return. One is wholly unable to disembarass oneself of an emotion of gratitude and religious reverence when, wandering alone among the elevated pastures of Switzerland, one encounters some of these venerable firs which for ages have been preserved as a refuge and a protection for the herd. One perceives in such localities the importance of the tree's mission. One feels that it is the friend and protector of all life. And well does every creature know it; goats, and sheep, and lambs, and indolent cows, spontaneously resort to its shade to enjoy their repose, each perfectly well acquainted with its own *gazon*—(the name borne by these protecting trees in the Pays de Vaud). There they establish themselves in the summer-time, and are at home. Near at hand the cascade murmurs. At different stages of the lofty tree buzzes and swarms a world of squirrels, insects, and birds."

THE INDOOR GARDEN.

BASKET PLANTS.

THE use of suspended baskets for conservatory decoration has now become so general, that a few remarks on the plants most suitable for their decoration may not be out of place. Formerly the plants grown in baskets consisted almost entirely of orchids, such as Stanhopeas, trailing Dendrobes, and the like; but now Ferns and Lycopods, Cacti, and succulent plants of various kinds are employed for this description of decoration; and why many other similar things are not used in the same way we do not know. No better way of examining the intricate beauty of some of the smaller melo-cacti could be devised, while a basket thoroughly well furnished with plants of Cereus flagelliformis, Mallisonii, and others of like habit, in full bloom, would be a sight worth walking far to see. The night-blooming Cereus, C. grandiflorus, would also be a grand subject for this kind of treatment. Again, for summer gaiety, what could be finer than a mixture of the brilliant orange, scarlet, purple, and silvery-white Mesembryanthemums? Of annuals, take the Portulacas and Clintonias; and for winter and early spring the various kinds of Tropaeolum, especially the varieties of T. lobbianum, and of the tuberous-rooted species, not forgetting our light and elegant friends T. tricolor, T. Jarratti, and the lovely blue T. azureum. If we go to foliage plants, the stove swarms with them—Gymnostachyums, Fittonias, Sonnerillas, Paucium variegatum, and such climbing plants as Cissus discolor, Lindenii, and porphyrophallus, the latter especially delighting in a position where, like the ivy, it can root from every joint. Nothing can look more beautiful than these foliage plants when brought between the light and the eye, the Iresines and the Dracennas being specially beautiful in such a position.

Perhaps, however, the finest examples of basket-gardening are the immense masses of the choicer kinds of Achimenes, as they may be seen in the Victoria house and large conservatory at Chatsworth. These baskets are very large, requiring, when filled with soil, four or five strong men to lift one, and each is stocked with hundreds of plants; so that when fully grown they form one dense mass of bloom, almost perfect spheres from four feet to six feet in diameter, and loaded daily for several months in succession with thousands of flowers. It is singular that the original species, A. longiflora and longiflora major and alba, patens, grandiflora, and Verschaffeltii do the best; the modern hybrids not succeeding at all. The preparation for these baskets at Chatsworth is almost like the preparation for bedding out in an ordinary establishment. The caterpillar-like tubers may be seen by the peck, and after a time dozens of shallow boxes with the young plants growing up like small salading. Still, grand as Achimenes are in their season, there is another tribe of plants, which, blooming—

"When chill November's sultry blast lays field and forest bare,"

is still more effective. This consists of the Epiphyllums; and, though the baskets at Chatsworth have been planted within the last two years, they have already assumed such proportions as to give ample proof that when the plants become fully developed they will form objects of great and novel beauty. The Epiphyllums are particularly suited to this style of decoration, for to realise their special beauty the flowers must be seen upon a level with, if not above, the eye; and the baskets can be raised or lowered, so as to bring out the bright tints of their richly-coloured flowers. The Russelia juncea, one of those plants which, twenty years ago formed one of our most elegant exhibition plants, has fallen almost out of cultivation. It is a free-growing, light, and airy stove plant, not unlike asparagins in its elegance, with long drooping branchlets, tipped in the blooming season with myriads of bright scarlet, slender, tubular flowers, each about an inch long, and not more than a tenth of an inch in diameter; and hence, whether in bloom or out, it forms

a very elegant plant. Its drooping habit renders it peculiarly suitable for basket cultivation, and, though one plant after two or three seasons' growth would form a very graceful mass, it is better for the purpose of immediate effect to plant four or five in a group. Assuming that you have a basket eighteen inches in diameter, and of proportionate depth, line the inside first with live sphagnum, to which may be added some of the smaller Lycopods. Then fill in with a compost, consisting of tough fibrous loam three parts, flaky, half-decayed leaf mould, and any cowdung made sufficiently hot over a fire or stove to destroy insect life and its ova, one part, and a liberal admixture of charcoal and broken oyster-shells, and some gritty sand. Mix the whole intimately together, having it at the time rather dry, and then fill the baskets quite firm. In the centre, however, place a soft porous six-inch pot, with the hole at the bottom stopped up, and this kept constantly filled with weak manure water will be found of great service, especially in the second and after years of the growth of the plants. Taken out and examined, it will be found that the roots of the plants have wrapped round it like a perfect network, and, if sufficiently porous, it is fair to conclude a large quantity of nutriment would be thus taken up. The basket being filled, procure some Adiantums and other small-growing ferns and Lycopods; fill them in as a fringe around the sides, and as they grow they will form a very desirable cover to the basket-work. Then plant your Russelias, placing them equidistant around the circumference of the basket, and cover the surface with a few more dwarf-growing plants.

The temperature of the house should be that of the damp store, 60° to 75° by fire heat, rising to 90°, with plenty of moisture in the atmosphere in bright weather. As the plants get established and the roots active, the syringe must be freely used with tepid water on all sides of the basket; and if sometimes clear weak manure water be added to it, the growth of the plants will be promoted. In the matter of watering plants in baskets, it is necessary that it be done thoroughly, so as to soak the whole mass of soil; and if this cannot be done by simply pouring water upon the surface, then the basket must be lowered into a tub containing sufficient warm weak manure to soak the whole mass thoroughly. For permanent plants this steeping of the soil will be necessary at the commencement of the growth in the spring, and perhaps once a month through the summer and autumn. This, however, will depend much upon the copious manner in which the plants are syringed; the surface of the basket being large, and the air hot and sometimes dry, the evaporation will be much greater than it would be from a pot or tub containing a similar amount of soil.

The branches of the Russelias, as they gain strength will rise to the height of five or six feet, and the branchlets, drooping in the most graceful manner, will form a living fountain of exquisite beauty. To bloom the Russelias successfully it is necessary that the maturing process be properly attended to in the autumn—that is, the quantity of water must be reduced towards the middle of August, the plants be exposed to full light and a free circulation of air, and in that manner the blooming principle is sure to be encouraged. Through the winter keep the plants dry rather than otherwise, but at the same time see that they do not actually flag. When growth commences in the spring, each tiny branchlet will be tipped with flower-buds in various stages of development, so that a succession of flowers will be maintained for a long time. Of course in the blooming season manure water must be supplied; and by copious syringing; sometimes with sulphur water, the plants must be kept clear of red spider, which is a sad pest to them.

W. A.

SUCCULENTS.

If Mr. Croucher's enumeration of Succulents at Kew is correct, I think the collection a meagre one compared with what it ought to be. Mr. Croucher sets Cactuses introduced into England down at about 550. In 1833 I made a collection that contained over 500 sorts, and there were at that time known to me above 150 kinds not in my collection. Prince Salem, of Dyke, Düsseldorf, on the Rhine, one of the greatest of Succulent authorities, told me that his collection of Cacti numbered about eight hundred sorts. Now, I am aware that during these last forty years there has been an immense number of Cactuses added to our gardens. The Duke of Bedford's collection, for example, was rich in many recently-introduced sorts; and many other private collections in England were far ahead of Kew in Succulents. My own at one time numbered 1,600 sorts, and was said to be the richest known in number of species. I had 500 Cactuses, 325 Mesembryanthemums, not including the annuals, of the Teneriffe Sempervivums, and about 20 hardy sorts; Euphorbia, 50 kinds; Aloc, in all its sections, 130 kinds; Stapelia, 80; and the rest were made up of many smaller groups, such as Sedums, Crassulas, &c. In the year 1837-38, I had the management of the Succulents in the Jardin des Plantes, at Paris, where there was a much finer collection under my charge than now

exists at Kew. It should be borne in mind that this was thirty years and more ago, and during that time one would have thought that the Kew collection would have reached at least two thousand sorts. There is a growing desire among cultivators to add these often beautiful and grotesque plants to their collections, and I can say that no tribe of plants presents so many interesting features as these do. A fine collection elicits the admiration of everyone. I have had the curious *Cereus abnormis* seven to eight feet high planted out in a niche, and along with it the singular *Serpentinus*, which grew up and twisted all round its rough partner, and covered it in a mass of beautiful flowers. It formed a truly lovely picture, which was admired by everyone who saw it. But I need not further advert to the merits of this useful tribe of plants. The increasing demand for something in addition to our flat beds of *Geraniums*, &c., is becoming every day more and more urgent, and I know of nothing that can add so much charm to a flower garden as Succulents. The combination of *Geraniums*, *Petunias*, *Lobelias*, &c., with finely-foliated plants, such as *Bocconia*, *Acanthus*, *Eryngium*, *Wigandia*, and the grotesque forms of Succulent vegetation, cannot fail to make our flower gardens objects of admiration. As regards noble plants, the Kew collection, though deficient in numbers, is in many respects unsurpassed.

J. SCOTT.

[In our own day the Paris collection of tender Succulents has always been very inferior to that at Kew.]

PALMS FOR THE GARDEN.

(Continued from page 396.)

MALORTIEA INTERMEDIA (SYN., *FENISTRATA*: CENTRAL AMERICA).—A handsome little plant, with erect palmate fronds; holed at the base, and a free grower, though small; useful for vases or for Wardian

Seaforthia Elegans (10 feet).

cases. This and the following species may be increased by cutting off the shoots that spring from the base, leaving them in the pot until they have become established.

M. SIMPLEX (BRAZIL).—A rather stronger plant than that just named, and without holes at the base of the fronds.

MARTINEZIA CARYOCELOFIA (PERU).—A noble palm, with dark, dense, arched foliage, something like that of *Caryota*, though denser; stem very spiny. An effective plant for the central portions of a stove, where shade is required.

OREODOXA GHIESBREGHTIANA (SYN., *VENTRICOSA*: BRAZIL).—A stately stiff growing plant, with broad spreading fronds.

O. OLERACEA (BRAZIL).—Elegant for furnishing purposes, and for towering up above other plants, so as to cause diversity of aspect. This and *O. regia* occupy a similar position among palms that *Poplars* do among hardy trees. Their fronds, which are slender, stand erect like a plume of gigantic feathers. *Regia*, which comes from Cuba, has narrower leaflets than *oleracea*, and is, altogether, the better of the two.

PHENIX.—The whole of the species belonging to this genus are much alike in habit; the fronds are regularly pinnate, and the base more or less spinose. For table decoration they are rather too stiff, but they make fine plants for stove and greenhouse ornamentation. The greenhouse kinds are *P. daetylifera* (Tropics: syn., *canaerensis*), and *spinosissima* (South Africa: syn., *leonisensis*). Stove sorts consist of *P. acaulis* (India), *P. paludosa* (Bengal), *P. reclinata* (South Africa), *P. rapicula* (India), and *P. sylvester* (India).

PTYCHOSPERMA ALEXANDRE (SYN., *PINANGA SMITHII*: NORTH AUSTRALIA).—A most desirable plant for the ornamentation of warm conservatories, in which its noble arched fronds of a greyish hue have a truly charming effect. A free grower, and when young very useful for table decoration.

P. RUPESTRIS (CEYLON).—A good stove palm, with the habit of an Areca, but with fronds tinted red.

PRITCHARDIA PACIFICA (PACIFIC ISLANDS).—Of all the palms having fan-shaped leaves, this is the finest. The leaves on plants only eight feet high often measure from four to five feet wide; they are flat and abruptly cut; the leaf-stalk being clothed with white scales, and the stem with strong fibre. A capital central plant for a close stove, in which its grandeur of outline could not fail to make it a favourite.

PHYTELEPHAS MACROCARPA (SYN., *ELEPHANTASIA*: TROPICAL AMERICA).—This though not a true palm has somehow been mistaken for one, owing doubtless to its resemblance to a palm. Its leaves are elegantly arched and feather shaped, and when young it is a good stove plant, but when old its appearance is anything but attractive.

RAPHIAS.—These are tall stiff growing palms from Tropical Africa, very fond of heat and moisture; when young they are ornamental, but in a few years they get rough and uninviting. The species are *R. Hookerii* (syn., *longifolium*) and *R. tectorum*.

RAPHIS.—These may be called humble palms; they throw up suckers so thickly as to form dense bushes. In pots, in windows, or in greenhouses, they have a fine appearance when kept to a single stem, which is erect, bearing fronds from eighteen inches to two feet long, nearly round, and cut into segments. All the species in this genus are moderately hardy, and are useful sub-tropical plants. They bear parting well. Of the Chinese *R. flabelliformis* there is a variegated form. *R. Sirotskii* (syn., *humilis*) comes from Japan.

SABAL.—This is a genus in which are to be found some of the largest of all palms, and where these have room to fully develop their fine fan-shaped leaves, that often measure from four to six feet wide, they produce a grand effect; on the other hand there are also in this genus small stemless plants which never grow more than six feet or so in height, as for example, *S. Adamsii* from Carolina, a nearly hardy species, though not a very elegant one. *S. Palmetto*, from the same district, is a tall plant, but not a very ornamental one; while *S. glaucescens* (syns., *grandis*, *principis*), from the West Indies, is a noble palm, with fronds five feet in width, of a glaucous green, and *S. umbraeifolia* (syn., *Blackburniana*), from the same locality, is also a very large plant. All the different kinds of *Sabal* will certainly live in a greenhouse, or even in a frame, if they could be got into it; but if required to grow they must have heat.

SAGUS RUFFIA (SYN., *RAPHIA MADAGASCARI*).—A good erect-growing palm of the pinnate class, with yellowish fronds; succeeds best as a sub-aquatic in a stove.

SEAFORTHIA ELEGANS (SYN., *PTYCHOSPERMA CUNNINGHAMII*: TROPICAL AUSTRALIA).—One of the most useful of all palms for vases when young, or for conservatories. The fronds are spreading, and very elegant. It is a kind that is easily cultivated, and it will keep long in a small pot.

STEVENSONIA GRANDIFOLIA (SYNS., *PHENICOPHORUM SEYCHELLARUM*, *ASTROCARYUM BORSIGIANUM*, AND *AUREO-PICTUM*: SEYCHELLES).—As its name implies, this is a plant with grand foliage, having a metallic hue and suffused with yellow spots. In stoves it is magnificent, especially when associated with ferns and other small-foliated plants. It is very sensitive of cold, and must have plenty of water.

The leaves are wedge-shaped, and its stem is clothed with strong black spines. If kept in heat it is a free grower. A large house and bottom heat suit it best.

J. CROUCHER.

(To be continued.)

REPOTTING AGAVES.

I AM anxious that no succulent-grower should become a convert to Mr. Croucher's mode of repotting Agaves (see p. 369), accomplished gardener though he be. Cutting off the plant below the collar is recommended, allowing it to root afresh, with the view of saving trouble and scratches. Nature seldom supplies us, in the vegetable kingdom, with anything superfluous: and why "crop off healthy roots"? a practice that holds good only when an Agave is "going to pot."

It is always two—sometimes four—persons' work to fresh pot a well-armed plant. Let it and the material in which it grows become dry; then place it on the top of a block, or hand-barrow, on a bright May morning, twist a piece of soft material, bay band or cloth, around the lower leaves, support it upright with this, smash the pot, prick out all the old loam with blunt sticks, cut off all decayed and a portion of the old roots, and leave the young ones (if any) alone. Into a well-drained pot, half filled with each man's favourite compost (who is not proud of his own peculiar mixture?), the plant should be lowered, filled in, and shaken fairly down; place it in the sun, in a few days the incised roots will have healed over, then water freely.

Decapitation may be both "simple and excellent," but it behoves us to be as conservative as possible in the management of such slow-growing plants as succulents. I say, preserve your crown and have mercy on the radicles.

SEMPERVIVUM.

FLYING FLOWERS AND RUNNING WATER.

PERMIT me to thank Mr. Noel Humphreys for his interesting remarks on flowers with wings. Talk of the charm of motion, methinks it will be all motion under glass when the flowers take wing. But they are only butterflies, to which has been given a charming name. They, however, often rival real flowers themselves in beauty of form and colour. What the last touch of the artist is to a work of genius these "flying flowers" may prove in our plant houses; I therefore bid the butterflies hearty welcome. But how are they to be kept in? The ventilating spaces must be netted over, and care must be taken not to let the winged flowers lose themselves in space through the open doors. With proper care this might be managed. Another point occurs: no butterfly that would be likely to prove destructive to choice plants in the larval state must be introduced among valuable plants, as it might be much easier to introduce flying flowers than to extirpate ravenous grubs. There seems no reason why tropical butterflies should not perpetuate themselves in our hothouses; but if not, doubtless a demand for chrysalids of different varieties would soon bring forth a supply; and in many hothouses the glory of tropical butterflies might add to the beauty, richness, and interest of tropical flowers. But there is another source of motion within reach of almost every possessor of a plant house, and that is, running water. The sound of this is one of our most satisfying pleasures; and yet how seldom it is heard under glass! Few sounds can equal in sweetness the liquid music of the droppings of water into a glass basin set on a narrow pedestal, or suspended in the air; and in all forms up from this to a torrent proudly dashing over artificial rocks, scarred and fretted with the wear and tear of the stream, or leaping over a sheer precipice into a dark gulf of boiling spray, running water ever gratifies and satisfies. There could be no great difficulty in having its gentle ripple at least made audible in many, perhaps most, of our plant houses. Thus, with running water seen and heard, and the air stocked with "flowers on the wing," we should be able to reap a richer harvest of pleasure from our glass houses than we even do at present.

D. T. FISH.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

A Simple Plan for Forcing Roses.—To obviate the trouble of keeping up a stock of roses in pots for forcing, we adopt the following plan:—About the end of October, or the beginning of November, we select a number of plants from the rose border (good forcing varieties); these are pruned in close, lifted carefully, and potted in nine, ten or twelve inch pots, as may be needful, potting them firmly in good sound loam. The plants are then set in the coolest house we have got till March, when they are introduced into heat, and pushed on into bloom in March, April, and May. From such plants we have had a display in April that

would not have disgraced an exhibition table. The plan is not so good as keeping a stock in pots, if these are well attended to; but there are many places where there is not time to do this properly.—J. S. W.

Spothy Cyclamens.—Would you kindly inform me by what means I may preserve my Cyclamen blooms from becoming spotted? My plants otherwise look strong and healthy.—D.—[Your frames or houses are possibly too damp for Cyclamens; they cannot withstand a damp or stagnant atmosphere. Where they are grown in the greatest perfection they are kept in houses to which is admitted a continual current of fresh air, and, to counteract its depressing effect on the temperature, a little fire heat is kept up. To some fire heat may appear unnecessary; but, without it, large flowers, pure in colour and plenty of them, cannot be obtained.]

Tacsonia Van-Volkemi.—This Tacsonia is, without exception the most beautiful of all greenhouse climbers we know, while its culture is always satisfactory, from the rapidity of its growth and abundance of its flowers. It thrives luxuriantly in conservatory, greenhouse, orchard house, or, indeed, any cool structure. It will do in a large pot, but it is much the best way to plant it out in a bed of earth, if such exist in the house; if not, it is well worth while making a special little brick pit for it, this pit to be filled with light and rather sandy soil, the plant then put in, and trained over the roof, or over slender arches, or up rafters. It flowers throughout the whole of the summer and autumn months. Wherever the drawing-room opens right into the conservatory—as is frequently the case—it would be well to plant thin that its suspended blooms may be seen from the interior.

Paul's Scarlet Thorn for Forcing.—We potted a dozen young trees of this last spring in twelve-inch pots, and plunged them outdoors. About five weeks ago we introduced six of the trees into a temperature of 55°, allowing a rise of 10° by sun heat. At this date (March 18th) they are coming generally into full bloom, some of the plants better than others, and best generally where the shoots have been pinched during the summer. After being another year in pots I fully expect the plants will force much earlier and bloom more profusely. I can scarcely imagine a more striking or more ornamental plant than the double scarlet thorn for the conservatory in the winter and spring months. In pots it is a plant that promises to force early, and with very little trouble. I have been thinking of potting a number of the common white hawthorn, as a match to the scarlet one. I have little doubt the one would force as well as the other. Who does not like the May? We send boxes of it to London every summer, and find that it is just as highly appreciated as the rarer exotics from the conservatory; and, no doubt, it would be even more appreciated in the dreary winter and spring months.—J. S. W.

Winter-Blooming Begonias.—Many of the Begonias are valuable for their winter-blooming qualities. They are very easily propagated by cuttings, and those who have not plants should lose no time in obtaining cuttings, which, inserted now in a gentle bottom heat, will quickly root, and form nice blooming plants by next winter. There are a great many Begonias that flower during the winter, but we shall confine ourselves to a few—in fact, a select list of the best species only, that may be grown either for the decoration of the stove, or to cut from in mid-winter. Begonia luxuriates in a light and moderately rich compost of turfy loam, peat, and leaf mould in equal proportions, with the addition of a little white sand. If watered with weak guano water, it will assist them in the production of flowers very materially. The following are some of the best winter-flowering kinds, of which descriptions will be found in the nurserymen's catalogues:—

B. fuchsoides	B. erecta multiflora	B. Dregii	B. Weltoniensis
B. nitida	B. Pearcei	B. Duvalii	B. Wagnerii
B. Saundersii	B. manicata	B. Ingramii	B. Scdenii
B. insignis			B.

PLANTING HIMSELF TO GROW.

Dear little bright-eyed Willie,
Always so full of glee;
Always so very mischievous—
The pride of our home is he.

One bright summer day we found him
Close by the garden wall,
Standing so grave and dignified,
Beside a sunflower tall.

His tiny feet he had covered
With the moist and cooling sand,
The stalk of the great, tall sunflower
He grasped in his chubby hand.

When he saw us standing near him,
Gazing so wonderingly
At his baby-face, he greeted us
With a merry shout of glee.

We asked our darling what pleased him,
He replied with a face aglow:
"Mamma, I'm going to be a man;
I've planted myself to grow."

—Mothers' Journal.

THE ALPINE GARDEN.*

CONDITIONS OF SUCCESS IN THE ALPINE GARDEN.

In treating of the culture of alpine plants, the first important consideration is that much difference exists among them as regards constitution and vigour. We have, on the one hand, a number of valuable subjects that merely require to be sown or planted in the roughest way to flourish—the common *Arabis* and *Aubretia* for example; but, on the other, there are many kinds, like *Gentiana verna*, and the *Primulas* of the high Alps, with many of their beautiful companions near the perpetual snows, which we rarely or never see in good health in these islands or elsewhere in gardens. It is as to the less vigorous species that advice is chiefly required. Nearly the whole of the misfortunes which these little plants have met with in our gardens are to be attributed to a false conception of what a rockwork ought to be, and of what the true alpine plant requires. These plants live on high mountains; therefore it is erroneously thought they will do best in our gardens if elevated on such tiny heaps of stones and brick rubbish as we pile together and dignify by the name of "rockwork." Mountains are often "bare," and cliffs are usually devoid of soil; but we must not conclude therefrom that the choice jewellery of plant life scattered over the ribs of the mountain or the interstices of the crag live upon little more than the mountain air and the melting snow. Where will you find such a depth of well-ground stony soil, and withal such perfect drainage, as on the ridges of débris flanking some great glacier, stained all over with tufts of crimson saxifrage? Can you gauge the depth of that narrow chink, from which peep tufts of the diminutive and beautiful *Androsace helvetica*? No; it has gathered the crumbling grit and scanty soil for ages and ages, and the roots enter so far that nothing the tourist carries with him can bring out enough of them to enable the plant to exist elsewhere. And suppose we find plants growing apparently from mere cracks without soil. If so, the roots simply search farther into the heart of the flaky rock, so that they are safer from any want of moisture than if in the best and deepest soil.

Alpine Flowers.

In 1868 I met on the Alps with plants not more than an inch high, and so firmly rooted in crevices of half-rotten slate rock that any attempt to take them directly out would have proved futile. But, by carefully knocking and peeling away the sides from some isolated bits of projecting rock, I succeeded in laying the roots quite bare, radiating in all directions against a flat rock, and some of the largest more than a yard long. We think it rapacious of the Ash, a towering forest tree, to send its roots under our garden walls and rob the soil therein, and are surprised at finding the roots of a tree more than a hundred feet

high descending a fifth or a sixth of that distance into the ground; but here is an instance of a plant one inch high penetrating into the earth to a distance forty times greater than it ventures into the alpine air! And there need be no doubt whatever that even smaller plants descend quite as deep, or even deeper, though it is rare to find the texture and position of the rock such as will admit of tracing them. It is true you occasionally find hollows in fields of flat hard rock, into which moss and leaves have gathered for ages, and where, in a sort of basin, without an outlet of any kind in the hard mountain, shrubs and plants grow freely enough; but in exceptional droughts they are just as liable to suffer from want of water as they would be in our plains. On level spots of ground in the Alps the earth is of great depth, and if it be not all earth in the common sense of the word, it is more suitable to the plants than what we commonly understand by that term. Stones of all sizes broken up with the soil, and sand, and grit, greatly tend to prevent evaporation; the roots lap round them and follow them deeply down. While in such positions, they

never suffer from want of food and moisture, or vicissitudes. Stone, it need scarcely be remarked, is a great preventer of evaporation, and shattered stone forms the dust as well as the subsoil of the mountain flanks where the rarest alpine plants abound. It should also be taken into account that the degradation so continually effected by melting snow water and heavy rains in summer serves to earth up, so to speak, many alpine plants. I have torn up tufts of them showing this in so marked a manner that the remains of many generations of the old plants were seen buried and half buried in the soil beneath their descendants. This would, of course, be effected to some extent

* An illustrated revision of the cultural and structural part of "Alpine Flowers."

by the decaying of the plants themselves, but very frequently grit and peat are washed down plentifully among them, and in such cases where these do not come so thickly as to overwhelm them completely, they thrive with unusual luxuriance.

Now, if we consider how dry even our English air becomes in summer, and that no positions in our gardens afford such moist and cool rooting-places as those described, the necessity of giving to alpine plants a treatment quite different from what has hitherto been in vogue will be fully seen. The only sound principle generally employed is that of elevating the plants above the level of the ground. Naturally protected in winter by a dry bed of thick snow, some of them cannot exist on our wet soils in that season, if not raised well above the level. But this principle of elevation should in all cases be accompanied by the more essential one of giving the plants abundant means of rooting deeply into good and perfectly firm soil, sandy, gritty, peaty, or mingled with broken stone, as the case may be. How *not* to do this is capitally illustrated by persons who stuff a little soil into a chink between the stones in a rockery, and insert some minute alpine plant in that. There is usually a vacuum between the stones and the soil beneath them, and the first dry week sees the death of the plant—that of course not being attributed to the right cause. Precisely the same end would have come of it if the experiment had been tried on some alp jewelled with Gentians and Primulas! Every one of these two brilliant families should have means of rooting a yard or more into a suitable medium. We should not pay so much attention to the stones or rocks as to the earth from which they protrude. There are certainly alpine plants that do not require a deep soil, or what is usually termed soil at all; but all require a firm roomy medium for the roots.

(To be continued.)

THE ARBORETUM.

JEFFREY'S BRITISH COLUMBIAN CONIFERS.

At a recent meeting of the Botanical Society of Edinburgh, Mr. McNab read the following paper on the discoveries made by Mr. Jeffrey and Mr. Brown, collectors to the Botanical and Arboricultural Expeditions from Scotland to British Columbia, between the years 1850 and 1866, with remarks on the cultivation and propagation of certain species:

PIEAS.

From my knowledge of Jeffrey's doings, said Mr. McNab, I am enabled to state that he was the means of introducing nearly as many novelties in the coniferous line as Douglas did while travelling in British Columbia between the years 1825 and 1833. Before leaving this country, Jeffrey was particularly directed to devote his attention to those kinds which were then exceedingly scarce in Britain, such as *Picea amabilis*, *P. grandis*, *P. nobilis*, as well as other genera and species previously introduced by Douglas. The two former species have never been received correctly from any other collector. In 1851, Jeffrey sent home cones and seeds of a tree under the name of *Picea grandis*. The Association, believing it to be correct, took no further notice of it at the time. Of recent years, seeds of this same *Picea* have been sent home by other collectors, named by one *Picea Lowii*, by another *Picea Parsonsii*, and under the former name it is now extensively cultivated. Very few plants of that long-leaved species must have been raised from Jeffrey's seeds, as original seedling plants are by no means plentiful. One raised here has been twice transplanted after being six feet in height, and is now a beautiful tree fifteen feet high, and thirty-six feet in circumference of branches. In its native state, Jeffrey says that it grows to the height of 280 feet, with a stem fifteen feet in circumference. Jeffrey has undoubtedly the credit of introducing this very handsome tree, notwithstanding the discussion which at various times has taken place about the naming of it. It therefore ought to have been called *Picea Jeffreyi*. The cones sent home by Jeffrey under the name of *Picea amabilis* are not the *P. amabilis* of Douglas. After the young plants were of such a size as to satisfy me that it was not that species, I provisionally named it *P. magnifica*. This is a most beautiful tree, perhaps the handsomest of all the *Picea* tribe. One of the original plants in the garden is now eleven feet high, and is easily known by its robust habit, pyramidal shape, and sharp rounded leaves, as well as the delicate bluish-green colour of the new foliage during the summer months, and the perfectly green state during the winter season. The cones of this

species were large, and had a peculiar curve in the middle. They were much destroyed by insects, which was the cause of so few being raised. Not many years ago a large quantity of the seeds of this variety were sent to Messrs Low, also under the name of *Picea amabilis*. The seeds, being good, were soon raised, and extensively sent over the country under that name. They are identical with the variety sent home by Jeffrey, and now called *P. magnifica*. Jeffrey also introduced a *Picea* which was figured and named by the Oregon Association as *Picea lasiocarpa*. This is a very free-growing tree, many of the annual upright growths being above three feet in length, on plants only ten and twelve feet high. These upright shoots afterwards become stunted by the free growing nature of the side branches. The largest plant in the garden is now twenty feet high, the circumference of the branches on the surface of the ground being forty-eight feet. Many of the seedlings recently raised in this country from north-west America, as *Picea grandis*, seem to be identical with the *Picea lasiocarpa* of Jeffrey, and totally different from the *P. grandis* originally sent home by Douglas.

ABIES.

Of the genus *Abies*, Jeffrey was instrumental in introducing three species previously unknown to British gardens; the most prominent being the *Abies Alberitana*, a species somewhat allied to the hemlock spruce. This is one of the most graceful of the tribe, particularly if growing on soils suitable to it, such as a peaty loam. Some of the original plants sent home were planted by the late Lord Justice-Clerk Patton, in what he called the Moor Pine-tree Nursery at the Cairnies, in Perthshire. They are admirable specimens, and must be now upwards of thirty-five feet in height, proving that peaty soil is the most suitable for their growth. The largest specimen in the Edinburgh garden is only twenty-five feet in height, growing in soil of a sandy nature. Notwithstanding that the *Abies Alberitana* is allied to the *A. canadensis* or hemlock spruce, the latter does not succeed here, nor has it the constitution of the *A. Alberitana* when seen growing side by side in situations where the *A. Alberitana* succeeds well. Other allied species sent home by recent collectors under the names *A. Bridgii*, *A. Mertensiana*, and *A. Williamsonii*, do not appear to be specifically distinct from the *A. Alberitana* of Jeffrey. Besides, the *A. Alberitana*, when growing in different soils and degrees of elevation, varies very much, which makes one think that it is identical with the three former named species; such, however, may not be the case when all are seen old enough to produce cones.

Abies Patoniana is another species introduced by Jeffrey, and one previously unknown in Britain. The *Abies Hookeriana* was also sent home by him at the same time. These two species, although somewhat allied in habit, are totally distinct when examined together. The leaves of the former are green on the upper side and whitish beneath, while *A. Hookeriana* has a uniform glaucous colour all over. The leaves also have no proper upper surface, being rounded, and densely set on the branches. The finest specimens of *Abies Patoniana* known to me are to be seen at Glen Almond and the Cairnies, great care having been taken of them by the late proprietor, whose name it bears. At my suggestion (many years ago), the side branches were foreshortened, which has given the plants an upright tendency. Both species are exceedingly hardy, and like the *Abies Alberitana*, luxuriate in soil naturally composed of loam and peat. As these plants have a great tendency to branch on the surface of the ground, instead of cutting them off, I would recommend them to be treated as layers. By doing so a great advantage will be gained by inducing in them an upright growth. The way I find the layering of these plants to succeed best is to bare all the lower branches of their leaves and small side shoots, leaving eight or ten inches at the point undone; then twist a very fine copper wire tightly round the lower portion cleared, and peg the branch down in a mixture of loam and peat, previously prepared and placed round the plant, covering the surface afterwards with a coating of sphagnum moss, and placing stones on the surface to prevent the moss from being blown about, as well as to assist to retain the moisture round the layers. If the layering practice is carried on for a few years, the plants will soon begin to assume an upright habit. I have never succeeded in striking either of these species by cuttings.

Several other species of *Abies* were also received under the names of *A. alba*, *A. nigra*, and *A. rubra*. Whatever the two former species may turn out, the last, *A. rubra*, is a very distinct-looking tree, with pendent branches and soft-pale coloured leaves. A good many seeds of this tree were distributed, but I have not been able to learn of any being planted in peaty soil, like the other species of *Abies* previously noticed. It is well known that most of the *Abies* tribe luxuriate in peaty soils, where the Norway spruce (*Abies excelsa*) is to be seen in its healthiest condition, as also the originally introduced specimens in Scotland of *A. alba*, *A. nigra*, and *A. rubra*.

(To be continued.)

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE SWEET-SCENTED VIRGINIAN RASPBERRY (RUBUS ODORATUS).

This forms a dense upright bush, from four to six feet high, with numerous stems. It thrives well in any good garden soil, flowering profusely in June and July, but more or less until September. It is a native of the Alleghany Mountains and the woods of Canada. It was first introduced into this country in 1700. The leaves are alternate, large, broadly five-lobed, unequally toothed on the edges, green above, more or less viscid beneath, sweet-scented and deciduous. The larger leaves are on longish, viscid, hairy footstalks, while those nearest the flowers diminish in size, are nearly stalkless, and mostly three lobed. The stems, which push up annually more or less from the ground, are erect, numerous and destitute of prickles, but are beset with viscid hairs when young. The flowers are in compound terminal corymbs, large, purplish-red, and nearly circular, consisting of five broad round petals. The fruit, which is seldom produced in England, is velvety, reddish-yellow or amber-coloured. This plant makes a fine display in shrubberies by means of its fine maple-like leaves, and especially in summer, when clothed with its showy corymbs of large purple flowers. The name *odoratus* was given to it on account of the leaves being sweet-scented, not the flowers, as is generally supposed.

THE SHOWY-FLOWERED CHINESE CRAB (PYRUS SPECTABILIS).

This forms a small tree, from fifteen to twenty feet high, which flowers profusely in the end of April or beginning of May. The flowers, which are of a beautiful rose colour, last a considerable time in perfection, and when the tree is loaded with them it forms one of the grandest objects that can adorn the shrubbery or pleasure-ground. It is a native of the north of China, whence it was brought to us in 1780; and no place, however limited, should be without it. The leaves are alternate, oval-oblong, somewhat pointed, regularly serrated, smooth and deciduous. The branches are rather crowded and erect when the tree is young, but afterwards, when it attains age and size, more or less spreading and slender. The blossoms are arranged in many-flowered terminal stalkless umbels, large, semi-double, and when in the bud-state, that is just before they expand, of an intense deep rose colour. The fruit is comparatively small, irregularly round, angular near the eye, on long footstalks, greenish-yellow when ripe, and about the size of a small Siberian or cherry crab. It is not eatable, and is produced but sparingly, owing to the flowers being semi-double.

FAMOUS TREES.

EVERY country possesses vegetable giants, and this, too, from the most different groups of trees. India has its Banyan; Africa, its Baobab; Germany, its Linden; England, its ancient Oaks and Yews; and California, its magnificent mammoth trees, which belong to the natural order Conifera, and which are upwards of three hundred feet in height. A Chestnut tree (of which we have given an illustration, see p. 37) is now growing on the side of Mount Etna, in Sicily, the stem of which is hollow, and one hundred and eighty feet in circumference. It consists, in reality, of several stems, which have grown together at their base, and whose crowns are concealed within one another. It is called by the natives, "Castagna di Cento Cavalli," because a hundred horsemen can find shelter in its interior. The age of this tree is unknown, but its immense size proves its great antiquity. It is indeed a noble tree, which has outlived and sheltered successive generations. By Neustadt, in the kingdom of Wurtemberg, in Germany, stands a Linden tree, which must have been very old in 1229; for an old tradition says that the city, which formerly was called Helmibundt, was destroyed in 1226, and was again rebuilt in 1229, "near the Great Linden." This Linden was so remarkable and well known, that for centuries the Germans were accustomed to speak of Neustadt as the city "near the Great Linden." In a poem written in 1408, it is described as growing near the gate of the city, its branches being supported by sixty-seven pillars. In the year 1664, there were eighty-two, and 1832, one hundred and six of them. They were built

of stone, and erected just as they were required, in accordance with the increase in the horizontal growth of the branches. The oldest inscriptions on these pillars bear the respective dates of 1558, 1562, and 1583, with the name and escutcheons of those who erected them. In the year 1832, the stem of this tree was, at a height of six feet above the ground, thirty-seven feet six inches in circumference. It must, therefore, have been from seven hundred and fifty to eight hundred years old, at the lowest estimate. Since 1832, it has suffered so much by tempests, that it is now almost, comparatively speaking, a complete ruin. Walnut trees, also, occasionally reach a great age. There is one in the Baidar Valley, near Balaklava, in the Crimea, which is at least a thousand years old. It yields annually from eighty thousand to one hundred thousand nuts, and belongs to five Tartar families, who share its produce peacefully amongst themselves.

There are Oaks now growing in England, which were planted before the time of the Norman Conquest, in 1066, and which are therefore more than eight hundred years old.

The Yew trees (*Taxus baccata*) are still older. One of these trees, located at Fountain's Abbey, near Ripon, in Yorkshire, was examined by Pennant in 1770, and was then more than twelve hundred years old; and another, in the churchyard of Brabourne, in Kent, according to the measurement of Evelyn, in 1660, had then attained an age of two thousand eight hundred and eighty years, and consequently is now more than three thousand years old.

The so-called American Cypress (*Taxodium distichum*), found in Florida, in southern Louisiana, and in Mexico, has not unfrequently, at a height of one hundred and twenty feet above the ground, a circumference of forty feet, and must, therefore, be very old. A fine specimen of this tree now grows in the garden of Chapultepec, Mexico, which was of an immense size at the time of the conquest of Mexico by the Spaniards, in 1520, and was then known as Montezuma's Cypress; and in the province of Oaxaca, in the same country, still stands the same Cypress which sheltered the troops of Ferdinand Cortez. These trees are at least four thousand years old; in fact, De Candolle considers them to be much older. But by far the most remarkable trees in the world are found in California. The Sequoia (*Wellingtonia gigantea*), popularly known in the district where it grows as the "Mammoth Washington Tree," was first discovered by the English traveller and naturalist, Lobb, on the Sierra Nevada, at an elevation of five thousand feet, and near the source of the rivers Stanislaus and San Antonio. These trees grow two hundred and fifty and even four hundred feet in height. The bark, which is of a cinnamon colour, is from twelve to eighteen inches thick; the wood reddish, but soft and light; and the stem is from ten to twenty feet in diameter. The branches grow almost horizontally from the stem; their foliage resembles that of the Cypress; yet, notwithstanding the monstrous size of these trees, their cones are only two inches and a half in length, resembling those of the Weymouth Pine (*Pinus Strobus*); whilst the Araucaria, or South American Pine, although far inferior in size to the Sequoia, produces cones of the form and magnitude of a child's head.

The Baobab (*Adansonia digitata*), of which we have given an illustration at p. 241, surpasses even the trees of California in grandeur and antiquity. It is the oldest vegetable monument on earth. Its stem is only from ten to twelve feet in height, but of immense proportions, for it is thirty-four feet in diameter. This colossal circumference is an absolute necessity; because, from its summit it unfolds so vast a leaf-crown, that it can only be supported on such a massive foundation. The main branch rises perpendicularly to a height of sixty feet, and from it branches extend themselves to a distance of from fifty to sixty feet horizontally on all sides; so that they form a noble leaf-crown, whose diameter is more than one hundred and sixty feet, giving to a single tree the appearance of a whole forest. The leaves of the Baobab are palmate, and forcibly remind us of the Horse Chestnut, being divided to the leaf-stalk. It is covered with great Malvaceous-like flowers, which drop on their peduncles. The fruit is about the size of a small gourd. In its native country, this tree bears a name which signifies "a thousand years"; and, contrary to what is generally the case, this name

expresses what is, in reality, far short of the truth. Adanson noticed one in the Cape de Verd Islands, off the coast of Africa, which had been observed by two English travellers three centuries earlier; he found within its trunk the inscription which they had graven there, covered over with three hundred woody layers, and thus was enabled to estimate the rate of the increase of the stem in three centuries. With this measure he succeeded in estimating the number of years' growth of the entire stem, and in ascertaining the age of the tree, which he found to be 5,150 years. These are a few, and probably a very few, of the remarkable trees with which the earth is adorned. The world has not yet been sufficiently explored for us to have become acquainted with all its remarkable trees; and lately we have learnt that some of the colossal gum trees of Australia surpass in size the big Californian trees.

But, although some trees live for thousands of years, yet the life of all must sooner or later terminate; for, to each tree, equally with the lowly plants which grow beneath its shade, a limited period of life has been allotted. This period may vary with the favourable or unfavourable circumstances in which the tree is placed, and depends also on the greater or less amount of life-force with which the embryo was endowed in the beginning; but, nevertheless, the life of all trees has its appointed period, like their form, altitude, and other specific peculiarities.

We close this chapter with the following list of trees, which is designed to show how the age of the same tree may vary. The—

Palm lives from					200 to 300 years.
Larch (<i>Larix europaea</i>) from	.	.	.	263 to 576	"
Chestnut (<i>Castanea vesca</i>)	,	,	,	360 to 626	"

Oak (<i>Quercus europaea</i>)	,	600,	800,	560, 1,000 to 1,400	"

HAROLD COULTAS.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Japan Privet.—This is so conspicuously useful and distinct a member of its family that we do not hesitate to direct attention specially to it, as though it is frequently planted, it is not sufficiently known. With leaves large and smooth like those of a medium-sized orange, and flowers somewhat like those of the white Persian Lilac, and growing from six to nine feet high, it has all the qualities for a first-class shrubby ornament. As a town shrub it has still greater value, because it will grow where most evergreens fail in towns, and may even be tried with confidence in a London "back yard."

Plants that Succeed in the Shade.—I have just taken charge of a place where there are a great many evergreen oaks, some of them very large. The greater part of the ground under them is quite bare. A few Laurustinus—illustrating the "struggle for existence"—and some Butcher's Broom make up the present undergrowth. I am anxious to exchange the bare soil for something more pleasing to the eye. Can you kindly assist me? The Butcher's Broom looks well, and perhaps Ivy would grow.—**ILEX OAK.**—[Try, in addition to Butcher's Broom, the Aucuba, various kinds of Periwinkles, English and Irish Ivy, and Berberis Aquifolium.]—J. BARNES.]

Aucuba versus the Cherry Laurel.—There can be no doubt of the Aucuba being decidedly the harder plant of the two, and admirably adapted for many purposes for which many other faulty things are employed in town, villa, and large gardens. No plant surpasses it in glossy beauty where evergreens run riot in wild places near our shores, while in towns it withstands smut and other detrimental agents better than any other evergreen. These are not only encouraging facts as regards the common Aucuba itself, but much more so when considered in relation to the male plant, and the many fine and striking varieties that have been brought to our gardens during recent years. The Laurel is often used for planting out railings and other objectionable surfaces, whereas over the greater part of the country the Aucuba is by far the better plant of the two.—*Henry Viner.*

Blighted Thorns.—Is the pink thorn liable to be blighted? I have a large specimen which must now be forty or fifty years old, and which last spring, just as it was putting out its leaves, was suddenly struck; the leaves dried up, and from that time to this the tree to all appearance is dead, except, on examining its trunk, and parts of its main branches near the stem, the sap still seems to exist. The whole head of the tree, which is a very well grown one, is, however, quite dead. Some years ago I planted a pink thorn in another part of the garden; this was struck apparently in a very similar manner about the month of June. The tree died off, and remained apparently dead all that year. It was in an out-of-the-way part; I left it to see if it would recover, and, to my surprise, the following year it sprouted and flowered as if nothing had happened, and has done well ever since.—MONTAGUE WILLIAMS.

NEW, RARE, OR NEGLECTED PLANTS.

SILENE PENDULA, VAR. BONNETII.

After the rose-coloured Silene pendula (so well-known from its general use in borders and in groups of spring flowers) we had the white-flowered variety (*S. p. alba*), and then the deep rose-coloured variety (*S. p. ruberrima*). A new variety has just been announced by MM. Vilmorin, Andrieux, & Co., who have named it after its raiser, M. Bonnet. It is a seedling of *S. p. ruberrima*, but is a great improvement on its parent; as in addition to its flowers being of a very deep carmine rose colour, the whole of the rest of the plant (stems, branches, leaves, and calyx) are of a very decided brownish red, which renders it a valuable subject for forming a contrast of colour in groups of other plants. The old *S. p. ruberrima* had the fault of growing in less compact tufts than the common rose-coloured kind; but the variety *S. p. Bonnetii* leaves nothing to be desired in this respect. If required to flower in summer, it should be sown thinly in the flower bed in February, March, April, or May; and for spring flowering, it should be sown in August or September in a nursery bed, and planted out either the same autumn or, in a general way, towards the end of winter.

LILIUM BLOOMERIANUM.

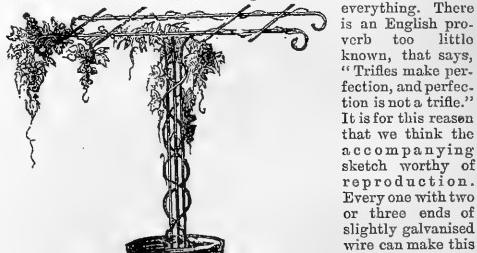

THIS is the most magnificent Lily of the Pacific coast. Its flower stalks are often ten inches to a foot in length, and so widely spread as to be slightly reflexed. Flowers, much more open and flexuous than the *L. superbum*; eight to twelve in number, or, in the most robust specimens, twenty to thirty. This Lily is easily distinguished from all others in any stage of its growth. The bulb is purplish. Its first bud above ground is always purple, which hue it bears in stem, leaves and bracts, in every stage of its growth. The cotyledonoid scattered leaves at the base of the stem perish early, as the proper whorls appear, leaving, however, scars to record their presence. The bulbs are larger than those of any other Californian Lily. It furnishes offsets sparingly, and is not "somewhat creeping," as in *L. pardalinum*, which produces offsets abundantly.

Root, a slightly oblong, broadly conic, scaly bulb, somewhat laterally compressed; scales lanceolate, fleshy, elliptically incurved; two to three inches long; somewhat loosely set; often oblique or progressively developed, but not creeping. Stem terete; very short-pubescent above and somewhat scabrous; purplish, smooth and glaucous below; six to eight feet high. Leaves broadly oblanceolate, acute or sub-acuminate; five to seven—rarely nine—nerved; nerves pubescent underneath; margins of leaves and foliaceous bracts slightly scabrous; waved, varnished above; glabrous and shining beneath; veins anastomosing or reticulate; whorled in verticiles of six to twenty mostly; somewhat scattered above and below. Peduncles alternate; long and widely divaricate—often at an obtuse or depressed angle. Flowers nodding, large, loosely recurved, bell-shaped; claws of the three inner petals short—about one fourth of an inch—and somewhat crested; claws of the three outer narrower petals longer—one half of an inch; light orange-colour, with madder brown velvet-like spots.—Dr. Kellogg, *Trans. Cal. Acad. Sciences*, 1872.

TOOLS, IMPLEMENTS, &c.

A NOVEL TRELLIS.

THE art of displaying plants with taste plays a highly important part in horticulture. It is nothing, and at the same time it is everything. There is an English proverb too little known, that says, "Trifles make perfection, and perfection is not a trifle."

It is for this reason that we think the accompanying sketch worthy of reproduction. Every one with two or three ends of slightly galvanised wire can make this little iron trellis in a very neat manner. It is handier than the commoner kinds of trellis, and the plants suspend themselves from it in a more graceful and airy manner.

EDOUARD ANDRÉ.

NEW PATENTS.

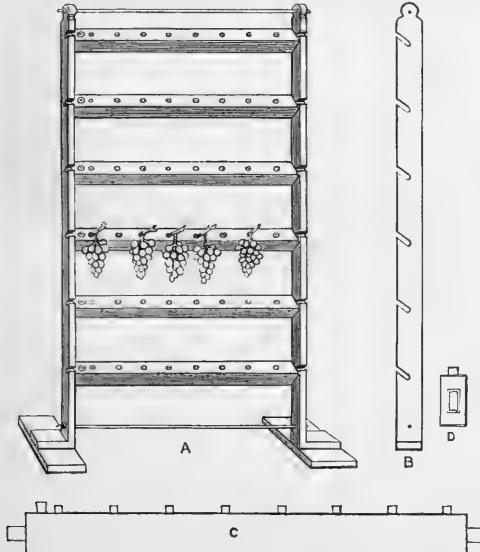

MR. HOUSE, Devizes, has patented an implement for extracting weeds and roots from lawns. It consists of a metal tube three-fourth inch in diameter and two feet six inches long, to one end of which is attached a foot piece or treader, and a short tube three inches long and one inch in diameter sharpened to a knife edge, and fitted with a plunger worked by a rod passing through the whole tube, and actuated by a lever handle. The tube has a cross handle.

MR. TAYLOR, Musseton, Lancashire, has patented an improved apparatus for sowing or distributing seed. It consists of a perforated cylinder driven by the main axle and revolving beneath a seed-box. The surface of the cylinder forms the bottom of the seed-box, and is perforated all over with recesses, each about the size to contain one seed. Above the cylinder a wire-guard lets the seeds pass, but prevents them from bearing heavily on the cylinder.

AN American patents a mode of colouring seeds to distinguish them from the soil, that they may be sown uniformly. The seeds are moistened, then rolled in flour till they are coated. This coating is further stated to aid germination, from its absorption and retention of moisture.

KEMP'S GRAPE RAIL.

WE have much pleasure in engraving a sketch of a new patent arrangement for preserving grapes in water, a practice now becoming common. This contrivance is the invention of Mr. Kemp, gardener at Albury Park, in Surrey, and mainly consists in the substitution of a zinc trough for a series of bottles. We believe it to be handier than the bottles. For the rest the woodcut explains itself. We hope this and similar contrivances may serve to popularize this mode of keeping

Kemp's Grape Rail.—A, front view; B, side view of support; D, end view of trough; C, side view of trough.

grapes, now generally admitted to be a great boon to the gardener. We were as fully assured of its merits when everybody was laughing at it as now when it is being widely adopted. As Mr. Hill, of Keele Hall, says, "There is no question about its being the right course to pursue with late grapes. It not only relieves the vines and allows one to clear the house, and utilise it for any other purpose, but the grapes may be kept perfectly for months."

The Shamrock.—It was some dim conception of the worship due to an adorable Trinity in Unity which led the Persians of old to reverence the threefold leaves of the shamrock as symbolic of a Divine Triad, to whom this plant was consecrated by the sons of Iran for many long centuries ere St. Patrick made use of the same green leaf to exemplify the same mystery to the sons of Erin. We may notice, by the way, that the name of the shamrock, like the idea it symbolises, claims to have reached us from the East; the word being identical in the Arabic.—Miss Gordon Cumming, in "Good Words."

THE PROPAGATOR.

THE ART OF GRAFTING.

(Continued from page 407.)

We have remarked in our garden that in bilateral cordons that is, when the stem divides right and left in the form of a T, the parts join easily enough in grafting by approach or lengthening; but as the sap meets in two opposing currents, the same uniformity of growth is not obtained as with the unilateral cordon.

USE OF APPROACH GRAFTING FOR INCREASING THE SIZE OF FRUIT.—This application of grafting by approach is not very common, as, in the first place, it demands some skill on the part of the operator; and, in the next, success does not always crown his work. We have, however, more than once seen its successful results, and especially with M. G. Luizet, arboriculturist

Grafting to increase the size of the Pear.

at Ecully, who in 1856 exhibited some fine specimens at Lyons at the inauguration of the Pomological Congress. About the month of June a young herbaceous branch is grafted by approach on the stalk of a pear, and bandaged with a woollen thread, which must not be drawn too tightly. If the branch continues to grow vigorously, the end of it is pinched; if it has ceased to increase in length, it is left as it is. The object is to secure a greater flow of nourishment to the fruit. When the fruit has come on the branchlet a feeding scion may be inarched upon the branchlet, in addition to the

Grafting to increase the size of the Peach.

scion on the fruit stalk. We have tried this with success. With fruits which have too short or too slender stalks, like the apple or peach, we must confine ourselves to grafting by ordinary approach, or inarching the herbaceous branch on the fruiting branch as near as possible to where the fruit of the branch will grow. The bandages should be tied so as to be easily opened without cutting.—C. Ballet's "*L'Art de Grefier*."

(To be continued.)

Propagating Camellias, Azaleas, and Epacries.—Could you kindly inform me how I can best propagate these plants?—C. H. P.—Camellias and azaleas may be propagated by inarching, grafting, and budding. The camellias on the single red, and the azaleas on some of the varieties of Phoenicea. Epacries may be increased by means of cuttings struck in silver sand under bell glasses on a slight bottom heat.

THE FRUIT GARDEN.

STRAWBERRY CULTURE.

AMONGST soft summer fruits the Strawberry stands pre-eminent, both in its fresh ripe state, and also as a preserve. It may be cultivated with more or less success in almost any kind of soil. It is, however, perhaps most at home in deep alluvial soils on the banks of rivers, or in a good deep loam resting on a well-drained clay; and though spring frosts sometimes injure the grower's prospects, still, generally under fair treatment, Strawberries are a certain crop.

Deep digging or trenching I look upon as all important; it helps to drain and warm cold heavy clays, and, by deepening hot, light soil, allows the roots to run down to a cool medium, thus enabling them to resist the heat and drought of a dry summer. Where the subsoil is bad, break it up thoroughly in the bottom of the trench, but do not bring it to the surface; simply breaking it up will let in the ameliorating influence of the atmosphere, and the rain will percolate through it more freely, leaving, on its way, the soluble manurial matter carried from the richer surface soil; and thus a gradual, but constant, improvement will take place in its character.

For heavy land, burnt earth or charred rubbish of all kinds may be applied with advantage, along with moderate dressings of lime and liberal manuring; but the manure should be trenched in deeply, and the lime, burnt earth, or a sprinkling of bone dust, spread on the surface after the digging, and be lightly forked in.

In the case of poor sandy soils, they also will be much improved by deep trenching, burying the manure moderately deep; and afterwards, if it can be obtained, spread over the surface at least an inch of clay or marl, and allow it to remain, if possible, exposed to the atmosphere several weeks, when, selecting a dry day, it may be forked in. But clay being the heavier substance, its tendency is always downwards; therefore, it is a mistake to bury it too deeply.

Although I recommend a liberal application of manure to land intended for Strawberries, still, one word of caution may be necessary, as it is for the inexperienced alone that these remarks are intended. It is possible, by using heavy dressings of rank manure only just buried under the surface, to defeat the object which we have in view—it is, in fact, possible to grow magnificent foliage with very little fruit; indeed, over luxuriance, as most people know, is an enemy to fruitfulness; therefore, trench deeply, burying the manure in the middle and bottom. The surface can easily be put right by top dressings, when necessary.

The best time for making new plantations is in August, although, in special cases, they may be made in spring. Such, for instance, as making a new plantation of the best of the plants that have been forced in pots. Such plants invariably do well, and bear an excellent crop the following season; still, in a general way, when young plants are used, August is the best month in which to plant. Let the ground be made firm before planting, and let each plant have room for individual development. There is nothing gained by thick planting, but rather the reverse; as not only is the fruit not so fine but much of it may be injured by the feet of those who gather it.

Plant in rows two feet from row to row, and eighteen inches plant from plant. Many good cultivators allow even more space, but, considering that two, or at the most three, years is the longest time I recommend the plant to remain on the spot, I think the above distances will be found sufficient. Where it can be done, it is best to lay the runners into small pots early in July; but many have not the time or convenience for doing so. It is best, also, to plant in showery weather. But August is frequently a dry month; therefore, when it is necessary to plant in dry weather, and the plants are not in pots, it is a good plan to mix together two or three bushels of damp earth, and short dung in about equal proportions, working them up into a thick stiff kind of paste, and when each plant is lifted, take a little of the plastic material, and place it round the roots, working it into a ball. A handy lad will do this a deal quicker than I can write it, and new plantations may be made in this manner in dry weather almost without a

leaf flagging. Soak the plants well as the planting proceeds, drawing a little dry earth round the plants with a rake, to check evaporation, and, unless the weather is very dry indeed, they will not require much further attention in watering. Always make it a rule to pull up all barren or unfruitful plants as soon as their true character is perceived. There will then be less difficulty in selecting prolific runners.

Unless very strong plants are used, they will not occupy all the land the first season; therefore, if it is desired to make the most of it, a light crop of some kind of vegetable or salad might be taken, without doing any material injury to the Strawberries. The best arrangement of this kind that has ever come under my notice is the following:—

Supposing the Strawberries are planted in August, and the ground hoed over the following March, the rows of Strawberries may be top-dressed with manure, and one drill of onions sown between every two rows of Strawberries in the centre of the space. I have seen splendid crops of onions grown this way without injuring the Strawberries. Make a new plantation annually, trenching up at the same time a corresponding plot of old plants.

Strawberries are, in a measure, surface-rooting plants; therefore, do not permit the spade to be used amongst them but when an intermediate crop of onions has been harvested the first season. After they are removed, and the runners cleared off in September, a dressing of manure may be lightly forked in the spaces between the Strawberries, taking care not to use the fork too close to the plants. Leave on all foliage till March, to protect the crowns during the winter; but in the spring dressing any old foliage that has been damaged by the winter's storms may be cut away, and the plants afterwards top-dressed with manure heavily all over the bed; and before the blooms open, place a layer of clean straw, long grass, or litter, of some kind, to keep the fruit clean. If the weather is hot and dry about the time the fruit is setting, a good soaking or two of water will be beneficial; but deep cultivation and heavy mulching will do away with the necessity for much watering.

The varieties of Strawberries are now becoming very numerous; but some of the best old kinds still retain their hold on public favour—a clear proof that they are not yet beaten. Although I think it is best to place the main dependence upon three or four varieties that have been proved in many situations to be trustworthy, still, at the same time, it is as well to bear in mind that this is an age of progress, and that there is a gradual improvement taking place in most of our cultivated plants. Therefore, I think it would be folly for those who wish to have the best of its class, to ignore new varieties; although, I have no doubt, many new varieties will come and go before some of our old favourites disappear.

In making the following selection, I have enumerated a few of the best old varieties, adding, also, several good new ones that I think may be depended on:—

KEENS' SEEDLING.—This is so well known, that little need be said about it. It is first-class in flavour, ripens moderately early, and the fruit packs and travels well.

PRESIDENT.—Firm, good flavour, bears well; one of the most useful.

BURISH QUEEN.—A well-known old kind, of fine flavour; in deep, warm soils is almost unequalled; rather tender.

CAROLINE SUPERBA.—Hardy, free grower; fruit, large, fine flavour.

TROLLOPE'S VICTORIA.—Strong, vigorous grower; very free bearer, and has the property of swelling off its late fruit almost as well as the first; does well in hot, dry soils.

ELTON PINE.—Large, high-coloured fruit, brisk flavour; one of the best kinds.

VICOMTESS DE HERICAUT DE THURY.—Ripens early, bears freely, fine high-coloured fruit; does well in difficult situations.

MARGUERITE.—Large fruit, of a pale red colour; very free bearer.

DR. HOGG.—Hardy, large, good flavour; highly recommended.

FROGMORE LATE PINE.—Very large pale fruit; rich flavour; good late kind.

If very early fruit is wanted, a few Black Prince may be planted on a warm border, and a few Elton or Frogmore Pine for a late supply of large fruit, in a north aspect, and the Alpine will continue the season till the end of October.

I am surprised that the Alpine is not more largely grown than it is. I know market gardeners, as a class, understand their interests thoroughly; but I have often thought it would pay them to grow the Alpine extensively for market after the other kinds of Strawberries were over.

E. HOBDAY.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Vegetable Crops in the Orchard.—Am I right in proposing to grow vegetable crops in a small orchard of pear trees?—[Perfectly right. We know of no better examples of good culture than some London market gardens, in which rhubarb and other vegetables are planted beneath the orchard trees.]

A Large Peach Orchard.—Colonel Edward Wilkins has now 1,350 acres, with 136,000 trees. The peaches from his orchard (near Chestertown, Maryland) are packed in crates, and sent to Baltimore to one factory, which contracts for the whole crop. In 1869 they netted him one dollar ten cents per crate; last year only thirty-five cents, or seventeen and a half cents per basket; yet, at this price he esteems it more profitable to grow peaches than to grow corn at the rate of sixty cents per bushel for a crop of sixty bushels per acre.

Sham Fruit Syrups.—It appears that a considerable trade is carried on in fruit syrups, which, on the *lucus a non lucendo* principle, contain no fruit whatever, but are artificially prepared from solutions of sugar, flavoured with ether, and coloured with aniline dye. There are, fortunately, various tests for this disgraceful imposture—such as nitric acid, which, when mixed in equal volume with real fruit syrup, causes no change, but turns the imitation yellow. With solution of carbonate of soda, the artificial remains unchanged, and the real becomes blue or green, so that the preventives against making our interior an ethereal dye-house are easily obtained, and put in force.

Freeing Starved Trees on the Quince Stock.—Cut several slits lengthwise (that is to say, vertically) into the back of the swollen part of the stem, at the point where the graft and stock meet. Extend the cuts upwards above the point of junction till they are three or four inches long. A bit of crock, or better charcoal, inserted in each slit to keep it from closing, will tend to the success of the operation. Then heap some good soil above all round up the stem, so as to cover the part operated on. Of course, the tree has never been disturbed during this process from where it is planted. The tree will soon throw out roots from the point of union and above it, and as the pear rapidly tends to outgrow the quince, the pear roots will gradually overcome those of the stock. Meanwhile, the tree will continue fruitful, as there is no sudden shock, but gradual change. It is a capital plan with trees on the quince in very poor dry soil.

THE KITCHEN GARDEN.

THE CUCUMBER—ITS CULTIVATION AND USES.

(Continued from page 437.)

AIR AND MOISTURE.

The necessity for air and moisture cannot be over-rated, for though many years ago some of our learned savans (Knight among the number) considered the ventilation to plant houses unnecessary, it is now established that the sturdy growth of the plant is proportionate to the free access of air, so long as that air is of the necessary warmth, and contains a proper amount of moisture. Dry, hot air is very destructive to the tissue of plants by drying up its moisture; but warm, moist air tends to the distension of the fabric of the plant, and to its performing its functions in the best manner. Plants that are naturally the inhabitants of shady places, and others with tender foliage like the Cucumber, require more moisture than hard-wooded or succulent plants. Plants of that description will not endure full exposure to the sun, except in the presence of abundance of moisture in the atmosphere, not because of an abundant decomposition of carbonic acid, which takes place in the presence of light, is injurious or otherwise than unfavourable to them, but because the epidermis allows the escape too freely by insensible perspiration, and hence they wither and die. In the admission of air into a forcing house—more especially during the prevalence of cold or north-east winds—it is most essential that it should be supplied with moisture before coming in contact with the plants, and if special provision is not made by evaporating troughs at the place of ingress, care must be taken, by sprinkling the paths and walls of the house, that the moisture shall be supplied before the foliage can be injured by it. No plant suffers more from a dry high temperature and a rapid current of air than the Cucumber. Its foliage is so tender that it is quickly dried up. This, in some measure, accounts for the success which attends the cultivation of the plant in dung frames, where it receives a uniform degree of moisture; but supply the same amount to a pit or house of larger dimensions, and success is greater, because there is a freer circulation of air and a larger atmosphere to feed from—for, be it known, plants feed almost as much from the atmosphere as they do through the roots from the soil. Should the plants at any time flag or

drop, they do so from the want of moisture in the atmosphere, therefore do not give more air to cool it, as some would advise, as that will only increase the evil, but immediately close the house or pit and sprinkle it, and, if necessary, shade it for a short time. The plants are suffering from the juices being carried away faster than the roots can supply it, and hence they wither and drop. It will thus be seen that it is by a proper apportionment and combination of light, heat, air, and moisture that success in plant management is secured. We have endeavoured to show that either in excess is injurious, and the same may be said of any deficiency in the quantity required. The careful cultivator will, therefore, so adjust his management as to secure these indispensable requirements in due and proper quantity.

THE CUCUMBER UPON DUNG BEDS.

This, though the original and perhaps not the worst system of management, is attended by so much trouble, and we might add danger, that but few follow it at the present time. Still there are those who delight in Cucumber culture who have no other resource from which to prosecute their favourite hobby. Pits and houses are too expensive for them, so that the Cucumber frame must still be considered one of the institutions of gardening. In years gone by the expense that used to be incurred to cut by means of dung heat a few Cucumbers in February was very great, while those who tried to get them by such means through the winter obtained them at an enormous cost. Most people who want this vegetable in quantity and perfection have their pit or house heated by a fire or hot water, and some of the working men in large towns make considerable sums of money by the sale of their surplus stock.

PREPARING THE DUNG.

The dung for the formation of a hotbed must be properly prepared—that is, it must be reduced to uniform consistency as to its state of decomposition; be rendered somewhat dry, and as free as possible from that rank fermentation by which so much ammonia is evolved. To that end, it is necessary that a quantity of stable litter be procured—say two, three, or more cartloads, according to the size of the bed to be formed. This must be thrown into a ridge six to eight feet wide at the base, and of proportionate height, taking care in the operation to shake every portion with the fork thoroughly out, and to mix the wet and dry portions regularly together. This will secure uniform fermentation; but, should any portion of the fresh dung be very dry, or in what is called a mouldy state, consequent upon being overheated, that portion must be sprinkled and made quite wet with fresh water. As soon as the mass gets to a good heat, which will be in a week or ten days, the heap must be turned again, observing precisely the same rules as to shaking the dung thoroughly out, mixing the dry and wet portions together, and sprinkling any part that may require such an aid to fermentation. To prepare dung properly for a hotbed, it will be necessary to turn it three, four, or, in some cases, more times; in fact, it requires to be turned until such time as it is brought into a state of uniform decomposition, dry rather than wet, and as free as possible from that rank steam which, when full of ammonia brings the tears into your eyes.

A.

(To be continued.)

How to Keep Tools in Proper Order.—Keep constantly in the tool-house a dry cloth and an oiled one. When a tool is brought in, as it is when the day's work is done, it should be cleaned and wiped with the dry cloth. If it is not to be used the next day, the oiled cloth is then rubbed over it. By pursuing this course through the summer, every implement is kept bright and ready for use. In addition to this, hoes, shovels, spades, &c., are kept sharp. All this time use lard-oil; but when the tools are laid by for a long time give them a good coat of linseed-oil. This forms a covering that is impervious to moisture, and the tool is as bright in the spring as when laid away in the fall.—*American Paper*.

Use for Charcoal Dust.—Elijah Low, Bangor, Maine, writes:—"I have a fruit garden of over fifty plum and pear trees, which, as a rule, bear regularly every year, and I have not used stable manure for twenty years. For ammonia (which all fruit trees need largely), I take a hoghead, bore several inch auger-holes in the head, then fill it with charcoal dust; into this I pour all the chamber-water, and not a particle of ammonia will escape. In a few months the dust will be so charged with this valuable fertilizer that in stirring it the effluvium will be nearly as strong as that from an old-fashioned smelling-bottle. This I dig in for my trees."

THE GARDEN IN THE HOUSE.

ON CHOOSING FLOWERS FOR DECORATING VASES.

THERE is, I am persuaded, more art in this matter than in arranging the flowers when they have been selected. It may be that you have leave to go into a well-stocked garden, and cut what you like; it may be, too, that you have a *carte-blanche* to get anything you fancy in Covent Garden Market. It has fallen to my lot on several occasions to be allowed to ransack the finest collections of Orchids round London, and to take away every flower I choose to ask for. These are opportunities on which much discrimination must be exercised; for, whether it be your own, or your friends' garden and houses that you are free to plunder, it behoves you not to take a single bloom that you cannot make good use of; to do so would not only be wasteful or extravagant, but, what is worse, it would be a selfish act, as it would deprive others of the chance of making use of them; and really good flowers are never so plentiful, that no one will buy or accept them. The circumstances under which I have thus far considered the selection of flowers are doubtless exceptional, as the majority of decorators have, as a rule, to exercise their choice of blooms under more or less restriction. In that case you must, in the first place, ascertain clearly what you can have and what you may not have. Go over the collection to be culled from repeatedly; calculate carefully which of the flowers are most suitable for the vases at your disposal, and mentally discard all those for which you have not a vase of the proper form, or that will not look well at the time, or by the time, they are wanted to look at their best, or that require certain foliage which you cannot command. Having thus eliminated what you cannot use, you must next group, "in your mind's eye," some of the remaining flowers, and think which will combine best to make the most effective arrangement for the intended purpose. All this may appear to some to be unnecessary; but they would soon alter their views if they were often asked to furnish a dinner-table with flowers for a few shillings, when to do it well would need the expenditure of as many pounds. It is under such restrictions that the comparative abilities of table decorators are most apparent.

I have often wished that some one would offer a prize, in competing for which the competitors should be restricted to one or more vases of a certain definite form and size, and to a certain specified list of flowers, with an intimation that the foliage was left to the discretion of each exhibitor, and that it was not necessary to use all the flowers mentioned. The list of flowers should include kinds that are unsuitable as well as suitable for the form of vase chosen. Such a competition would afford a better test of skill in arrangement than any prize that has yet been offered. If such a prize were to be offered, the art of choosing flowers would be illustrated by the results produced; and it is not at all improbable that the best effects would prove to have been made with the smallest variety of flowers. W.

CONCEALING POTS UNDER DINING-TABLES.

PLANTS would, I am sure, be oftener used for the decoration of a dinner-table if the difficulty of hiding the pots could be got over. Covering a flower-pot with common fern fronds, which have been stuck round the edge and bent over, is probably the best way of concealing the heavy block of dull red colour. I like this better than any pot covers I have yet seen, be they silver, gilt, glass, china, terra-cotta, or wood. When the plant is a fern of suitable character, it looks well at the apex of a pyramid of moss decorated with flowers; the only objection to this way of hiding the pot is, that the width of the base of the pyramid is often too great for a narrow table.

After trying every scheme that I could hear or think of, there is, I am convinced, no plan so simple and so manageable as that of putting the pot through the table. The expense of arranging the table to do this is very trifling, and the necessary alteration does not affect the appearance of the table when it is not used for this special purpose.

The following illustration shows how easy it is to fix a supporting shelf under the table to receive the pot, which can thereon be blocked up until its rim touches, or nearly touches, the under surface of the top of the table. But it does not show how the stem passes through the table top. This is, however, easily explained. A spare leaf for the table must be made; but as it need not be more than three or four inches wide, and of any common wood, unpolished, this addition to the household furniture will not be a costly one.

This spare leaf is to be cut into two pieces by the removal from its centre of a piece three or four inches long. Then on the table being put together, there will be a square hole in the middle of it, through which a flower-pot can be dropped on to the shelf below, or if the pot is too large to go through the hole, the plant must be placed upon the shelf first, and the leaves of the table afterwards pushed into their places over the pot.

If it be wished to apply this principle to tables which are not to be covered with cloths, the only additional expense will be that of the wood of this extra leaf being of the same kind as that of which the table is made, and of its being polished.

The drawing herewith shows a plant of white Bouvardia passed through a table. The pot was filled up with good moss. The table cloths having been duly arranged, some good fronds of Maiden-hair were stuck into the moss, some lying on the cloth, whilst amongst them were arranged a few blooms of Scarlet Geraniums and cream-coloured Chrysanthemums. The effect of a series of these groups, placed at intervals down a set of long narrow tables in a large room, was very pleasing and much admired.

Some may be disposed to think that they could produce as good an effect without using the plant as I have described, and without a hole through the table. Let them try it, and they will find out that they are wrong, that is if they are not to be allowed to cut up the plant. Of course the same effect can be obtained by sticking branches of Bourardia into a lump of clay upon a plate, and finishing it off as before mentioned; but then the plant is destroyed. On the other hand, by putting the pot through the table, the plant can be used repeatedly all the time it is in bloom, and after blooming is over, it can be saved for use again next year in the same manner. With rare and valuable plants this is an important consideration. T.

AUTUMN LEAVES.

I THINK it was Professor Owen who first divested falling leaves of all pensiveness, by showing that they fell, not because an old leaf had died, but because a new leaf was born. I am sure Mr. Ruskin will excuse me for directing attention to this more cheerful view of the matter; it is in strict accordance with science. The leaf is pushed off by the advance of life—not blasted by the breath of death. The new bud at its base gives it notice to quit. By-and-by that notice becomes so urgent, that it cannot be resisted; the swelling bud becomes so large as to push the old leaf off. Possibly Professor Owen may favour us with his version of the matter in his own words, which would be so much better than mine. This hopeful view of the falling leaf has given me much pleasure, and I wish others to share it. It shows life, not death, to be master of the situation even in winter. This new truth ought to lay the foundation of a new school of poetry. The old is saturated with the fall of the leaf as the symbol of death. On the contrary, it is the proof of life ever pushing onwards, and never stopping until the final terminus—the death of the individual—is reached.

D. T. F.

[We are not aware that Mr. Ruskin took a lugubrious view of the fall of the leaf.]

GARDENING ROUND LONDON.
(DURING THE PRESENT WEEK.)

PRIVATE GARDENS.

Indoor Plant Department.—In conservatories, Hyacinths, Tulips, and Primulas, now nearly over, are being succeeded by such things as Rosas, Azalas, Rhododendrons, Cianthus, Cyrtisus, Heathis, zonal and the earlier-flowering fancy Pelargoniums, that have been brought forward in a little warmth, Imantophyllums, Amaryllises, Acacias, and Salvias; to which are added some of the freer-flowering Odontoglossums, and such stove plants as Begonias, Eucharis, Ixoras, Stephanotis, Torenias, Gardenias, Clerodendrons, &c.; these and the orchids are placed in the warmest part of the house, where they are free from draughts. No fire heat is used now in conservatories or greenhouses if it can be avoided; but in cold weather such houses are shut up early, so as to make the most of the sun heat.

Flower Garden and Shrubbery.—Such spring-flowering plants as Heartsease, Daisies, Iberis, Roman Hyacinths, early Tulips, Narcissi, Alyssums, Aubrietas, Anemone apennina, Periwinkles, Trollius, Corydalis, Doronicums, Fritillarias, &c., are now quite gay; as are also such handsome-leaved plants as Golden Feverfew, Cornsultums, variegated grasses, the dark brown-leaved Ajuga, variegated Arabis, and Polemonium, all of which serve to make beds and borders quite attractive. Violets done blooming are divided and replanted. Hardy annuals, such as Saponaria, Nemophila, Collomias, Alyssum maritimum, Clarkias, Virginian Stocks, Silene pendula, Mignonette, &c., for early summer flowering, are now sown, some where they are to remain, and others on well-sheltered borders for transplanting. Viola cornuta and lutea are lifted, divided, and replanted, so as to make nice plants for summer bedding.

Indoor Fruit Department.—To Pines is given an increase of temperature and moisture. Suckers as fit continue to be taken off and potted. As Grapes begin to colour, the amount of humidity in the air is gradually lessened. To such as are stoning a steady moist temperature is maintained, and care is exercised to guard against cold currents of air. Thinning, stopping, and tying of shoots are operations which at all times receive attention. To Peaches and Nectarines a steady moderate temperature is kept up. Succession houses have their fruit thinned, but too many are not removed until after the stoning period has been successfully passed over, when they are thinned out to the required distances apart. Strawberries for succession continue to be introduced, and the last batch of them is placed on raised boards in frames or near the glass in cold pits; to such as have set their fruit a little manure water is given, but this is discontinued as soon as they begin to ripen. Melons and Cucumbers are timely thinned, which prevents depriving the plants of so much foliage at once. Seedling Vegetable Marrows fit to handle are potted singly, and such as are established are planted out in frames and protected. Endive is still sown in brisk heat and gradually hardened off. Kidney Beans are also sown in frames, in lines about eight inches apart, and where failures have occurred they are made up from parts that are thickest.

Hardy Fruit and Kitchen Garden Department.—Peach trees have some of the least promising newly-formed fruits removed, in order to strengthen those that are better developed. Plantations of Artichokes continue to be made, and established ones to be top-dressed. Seakale is being increased by means of seeds and divisions of the roots. Asparagus seeds are still sown, some where they are to remain, and others on beds for transplanting. Kidney Beans are sown on warm borders, and Windsor Beans are now sown for late main crops. Another sowing of Peas where necessary is also made on deep, well-manured ground. Cauliflowers are also sown, and such as have come up are being picked out four inches apart. Cabbages continue to be planted out wherever room can be found for them. Of Broccoli small sowings are still being made. Round-leaved Spinach is sown between lines of Peas. Of Lettuces new plantations from thinnings are made as required. Sowings of White Dutch Snowball and of Red and White stone Turnips continue to be made. Main crops of Carrots and Parsnips are now sown on deeply-trenched ground. Mustard and Cress are put in in small patches on wall borders, and if necessary have a mat or some other kind of protection thrown over them. Radishes continue to be sown in succession.

NURSERIES.

Indoor Department.—Young hard-wooded greenhouse plants, now that they have started into growth freely, are being pruned back pretty closely, so as to make nice shapely plants for next season. The prunings are used for purposes of propagation. Certain sorts of Heaths are treated in the same way, and where the pruning has been neglected last year they are cut well back into the old wood. Such as are thus cut back have not been reported this

season, but are kept in dry, airy houses; and, if necessary after they have started, they will be repotted. Roses are being raised from cuttings under handlights well shaded. Autumn-grafted Camellias are having their ligatures loosened; and spring "worked" ones are kept close, and well shaded. Acrophilum venosum is, in some places, being raised from seed in gentle heat; as is also Mandevilla sacerolens. Grevillea Banksii also comes pretty true from seeds; as does also Anthurium Scherzerianum; the seeds of the latter are collected as soon as ripe, and the pulpy substance is washed away from them; small pots are then filled to the extent of one-third with drainage, over which, to within three-fourths of an inch of the brim, are placed well-chopped sphagnum and fibry peat, on the top of which is placed a thin layer of finely-sifted peat, mixed with silver sand in equal proportions. On the surface of this the seeds are placed; but they are not covered, merely lightly pressed into the soil. The pots are then covered with squares of glass, and plunged in coco-nut fibre under handlights, in a shady part of the propagating house, where they germinate in less than a fortnight; bottom heat is unnecessary. Roots of tender Nymphicas and other tropical aquatics are being potted and started in stove aquaria. Caladiums which have filled their pots with roots are shifted into larger ones before the roots become matted. Bignonias, Aristolochias, Beaumontias, Clerodendrons, Combretums, Hoyas, Manettias, Passifloras, Tacsonias, Stephanotis, and other stove plants, are being pruned back, and the prunings are being used for cuttings. Grafting the finer kinds of Conifers still continues to be done, after which they are kept closely shaded in frames in gentle heat.

Outdoor Department.—The grafting of stone fruits, such as Cherries, Plums, &c., has in most cases been finished; that of Pears is also nearly finished, but Apples are still being "worked," as are also many of the finer kinds of hardy forest and ornamental trees. Where last summer's buds have failed, the stocks are re-grafted this spring. Where young fruit trees are required for training, they are pruned back to within a few eyes of the old wood; but where they are kept for standards, they have only a piece of the point of their main shoots cut off, and the lateral branches removed. Ground that has become empty is filled with stocks for operating on next year; they are planted as the trenching proceeds. Any empty spaces amongst large trees are filled up with cuttings of Plancs and other trees; or Seakale roots are planted amongst them in lines for lifting for forcing. The main stock of herbaceous plants is now being reported and set outside on north borders, on which a layer of ashes has been spread. Gladioli are being planted in beds. Tulips, Hyacinths, and other bulbs done flowering, are placed in cold frames and outside in shady borders, where they are allowed to ripen.

MARKET GARDENS.

VEGETABLE MARROWS are being sown; some are potted off singly, and others are planted out in frames. The frames are prepared by digging a trench about eighteen or twenty inches deep, filling it up with hot manure, over which is placed the compost; wooden frames are then put into position, and the plants planted, and, should the weather prove severe, a cover of litter is placed over the sashes at night. Vegetable Marrows are also planted in lines about ten feet apart, and six feet plant from plant. Under each plant a hole is dug, and a barrowful of hot dung placed therein, and over which is put the mould. The plants are planted, and a handlight is placed over each, or round vegetable baskets are substituted where handlights are scarce. A little soil is placed around the base of each light or basket to prevent a current of cold air. Between the Vegetable Marrows are Radishes, or the space is filled up with Lettuces. Tomatoes are gradually hardened off. French Beans are sown in lines on sheltered borders, and two lines are sown on the tops of each of the Asparagus beds. Those grown in frames are now up, and deficiencies are made good from a reserve stock by transplanting with a dibber. Between the beds of early Carrots raised in frames, Lettuces or Radishes are sown. Seakale roots that were preserved from those lifted for forcing have been cut up into pieces about the size of a man's finger, and laid pretty thickly on the surface of a bed with a few inches of soil placed over them; they are now emitting eyes and young roots, and are lifted and dibbled in in lines between the rows of Cabbage plants. Some of the finest Cabbages have pegs placed beside them, so as to mark their place as the stock is cut for market, but the stump is retained for seed. Radishes continue to be sown in beds. Sowings of Spinach also continue to be made; and on new Cauliflower plantations a sprinkling of seed is sown broadcast. Cauliflower reared under handlights have some soil drawn up around their base. Mushroom beds in the open air are in good bearing condition; on gathering the surface litter is removed with steel forks into the alley between them, the produce collected, and the covering immediately replaced.

SOCIETIES, EXHIBITIONS, &c.

ROYAL BOTANIC SOCIETY.

卷之三

The ornamental features of this show were collections of stove and greenhouse plants in flower; Anemones, Roseas, Cyclamens, Herbaceous plants, Hardy trees, Biophilous shrubs, and wild life, among which was a gorgeously winged plant of *Desmodium* Radiata.

There were also some good groups of stone plants, conspicuous among which was the lovely Clerodendron Balkanicum. In this class, as well as in that of greenhouse plants, Mr. Ward was first.

In the Americas were very numerous; a group of small plants from M. Van Houtte of Ghent, Belgium, were described; several others were some new kinds of considerable promise. To the author's knowledge there were no new species of *Franseria*, *Glechoma* or *Walsia*, a small annual rose, *Messerschmidia*, double rose, Dr. D. Moore, 1905; Alice, sweet-scented like the last, John Gould Veitch, 1905; the plants of the genus *Hedysarum*; *Cynometra* is becoming more popular; the author has received the seeds of several new kinds; he has also received the seeds of *Psychotria* determined with some difficulty, and *Marcosia* of Lame, the single variety seen so far. A few small plants from Messrs. F. & A. Sander of Düsseldorf possessed good symmetrical flowers; amongst them *Baileya* of Sprengel received a certificate. Messrs. Lane & Sons were due for accolades; and

they also showed well dressed Rhododendrons in pots.
Amaryllis were shown in good condition. Mr. Barron, before the
meeting, took the competition for a group of six Grand tuberous
begonias and again gained by Messrs. Gandy and Clark. Mr.
Wardlow being present with a variety of weaves, and Mr. Clark several
bird nests which in intricate mystery were shown by Mr. Wink, of
London, to whom was awarded a first prize.

Not a few plants of great interest were exhibited by Messrs. Veltma. Among them was a new *Thlaspias*, the flowers of which have a deep reddish tint. To this a certificate was awarded. The same plant was also exhibited under *Crocos*. *Weinmannia* is the species, with yellow leaves, the midribs and edges of which are blushed with red. *Mastostachys* *Eurycoma*, which was exhibited, also received a certificate.

Mr. Fred Nelsonton, from Messrs. Ballou & Sons, a certificate of merit was awarded. This is a superb bird with feathers of a very rich color, dark brown on the back, down on both sides of neck and a white

LITAL HORTICULTURAL SOCIETY.

EDWARDIAN LITERATURE SOCIETY.

The following are the titles and regulations in connection with the
show of dinner-table decorations to be held at Smith's Restaurant May
20th.

- The route for 10 passengers will be 11 feet long, 1 foot 6 inches broad; 3 places will be available for the driver.
- The route for 12 passengers will be 11 feet long, 1 foot 6 inches broad; 3 places will be available for the driver.
- The route for 14 passengers will be 11 feet long, 1 foot 6 inches broad; 3 places will be available for the driver.

IV. Each chamber will have a separate compartment in which crested for the occasion, so that each exhibitor will have a private room to himself, and a separate staircase will be provided for his convenience.

VI. The tables and furniture may be furnished by the school committee or such relatives as said messrs. Day, etc. The Society will supply the rest.

VII. The following appendices are enclosed—namely, the flashes, summary, tables, and other documents sent from time to time.

The competition will be judged as far as distance by daylight, as stamps or certificates are awarded to the first.

The Society will not be responsible for loss or damage to exhibits in the objects. It is the responsibility of the Society to ensure the safety of the objects exhibited, an officer will be present in charge of each separate compartment and the visitors called on the assurance of the Society, but the Society will not be responsible for any loss or damage.

I trust you will agree that £100 are placed at the disposal of the implement committee belonging to this exhibition for appreciation in the shape of five gold medals; one for the best horticultural building, one for the best hot-water apparatus, one for vases, &c., one for garden machinery and tools, and one for wire-work, &c. Now with regard to these awards which come under the three latter headings, I expected that after the question of lawn-mowers has been decided, the judges will experience little difficulty in arriving at a satisfactory selection of each of the remaining mentioned articles as come within these classes; but with respect to the "best" horticultural building I am not so sanguine. By what standard of excellence are these structures to be judged? Is it to be a consideration of size, quantity erected, construction, or variety in design, or good materials and workmanship, or utility, or of interest?

arrangements, &c.? Again, of what is the building to consist? A conservatory, viney, peach house, pinery, orchard house, plant store, pit, or a hand glass? Some instructions on these points should surely be issued, and the buildings classified; otherwise one kind of building will be competing against another of a very opposite character, and this will create much confusion and dissatisfaction.

character, and this will create more confusion and dissatisfaction. As regards the best horticulturist appears, that is really a knotty question. First: Is the apparatus to be working or not? Second: By what test is it to be considered as being the "best"? Third: Is the competition to resolve itself into the long-talked-of trial of "borders"? If so, where are the conditions and regulations to be found? What is to be governed? Fourth: By what special points are the judges to be guided in making their awards? And finally, what are the qualifications necessary to constitute a competent judge, capable of giving a just decision in this important matter? I am of opinion that the judges should be men of scientific attainments in good position, and entirely outside the horticultural world, as engineers, &c. They should, in short, be above suspicion of being influenced by trade considerations or personal interests.

LAW.

FENNEMORE AND OTHERS v. SPICE.

This was an action for alleged injury to crops, hedges, and herbs, arising from chemical works at a place near Egham. The object of the works was to utilize the products of the manufacture of gas. Last year complaints were made by the plaintiffs that the pitch or tar refuse of the works flowed into the ditches, and soon after that a salt plain was sited in the Chertsey County Council. The defendant removed the case into a superior court, and it now came on to be tried, the plaintiff claiming about £150 in respect of loss. For the defence Dr. Voelcker said there were no fumes generated in the defendant's works which were injurious to vegetation; and as to the smoke, it was not in that respect like ordinary smoke, which was more or less mixed with sulphuric mists, very deleterious to vegetation. Furnace soot, he said, was so far from being injurious, that it was an excellent manure, and no amount of the black product at these works could be deleterious, nor was there anything at all produced in the works injurious to the heritage. Acid fumes, he said, always showed their effects unmistakably on the top parts of plants—the tender shoots; but there were no traces in the plants of the effects of such injury.

The Lord Chief Justice, in summing up, said, there was no evidence of injury from sulphuric acid, which it was admitted was injurious to vegetation. Certainly there was smoke accompanied by the deposit of blacks, which gave the vegetation the appearance of being burnt. But then it was only the appearance, the evidence showing that the vegetation was not really burnt up. As to the soil, the scientific evidence showed that it was rather a benefit than otherwise to the soil; and the evidence was, as matter of fact, that where the blacks had fallen the grass had grown more luxuriantly. As to the supposed burning up of the hedges and hortage, according to the evidence for the defence, there was nothing in the works to cause any such injury; and so as to the alleged grievance of allowing ditch and ear to draw into the ditches. On the whole case the jury must say whether the plaintiffs had made out their claim, or not.

The jury consulted together for some time in the box, and then desired to retire to consider their verdict. While the jury were in deliberation, the parties, at the suggestion of the Lord Chief Justice agreed to terms of settlement, a jury being withdrawn.

ANSWERS TO CORRESPONDENTS.

GARDEN

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—Shakespeare.

HOME LANDSCAPES.

GARDEN BEAUTY IN MARCH.

NEVER is a well-planted pleasure garden without beauty of some kind, not even in the depth of winter. Sometimes, during the leafless season of the deciduous trees, the hoar-frost makes them more beautiful than even in their summer leafage, transforming their slight terminal branchlets into the semblance of spangled feathers, more delicate and graceful than the artificially-curled plumes of the ostrich or the weeping wings of the bird of paradise. At other times, snow-laden branches produce a grand and impressive effect; and again, after heavy winter rain, when every branch is dripping with glistening globules, bright as liquid diamonds, the true lover of garden scenery perceives another variety of attraction not less charming. But it is in early March—the first month of spring promise—that garden scenery enters the most attractive epoch of the leafless period.

In March, though the branches of deciduous trees are still unclothed with their many-tinted robes of green, the buds are already beginning to swell. Those of the Horse Chestnut become magnificent in their highly-varnished husks of glowing brown. Ash buds, as they enlarge, become conspicuous by their soft, full black—a blackness deep as that of unpolished ebony. The young leaves of the Lilac, of pale, sunny green, begin to unfold, and at the end of every leading branchlet disclose miniature models of the bunches of flowers that in another month will weigh down many a blooming branch with their rank luxuriance. These signs and prophecies of coming summer impart an infinite charm to the garden in March, and there are many other such; for instance, the grey, silken envelopes which contain the florets of the Willow tribe, and the small rosy cone-blossoms of the graceful Larch. And while many trees are only in a state of forward promise, others have already burst into bloom. The Cherry-plum is covered with a mass of white—a very snow of flowers. And how glorious is March with its Almond trees, whose very branches are hidden with the profusion of rosy-hued bloom! a display which, despite its glorious beauty, is yet compelled to succumb to the dazzling scarlet of the close masses of blossom that crowd every limb of the Cydonia japonica, when deftly trained against some coigne of vantage, or revelling as an untrained bush in some sheltered nook, where no east wind can pay its unpropitious visits, but where the rays of the southern sun have free and uninterrupted access. Surely, this list of beauties is enough to prove that the March garden offers a very charming display of many and various attractions; and even where blossoms, or swelling leaf-buds, brown, and black, and pink, and grey, are absent, many deciduous trees, leafless, bloomless, and budless, have yet a peculiar charm of their own; for their delicate branchlets, in endless variety of characteristic and minute ramification, define each of their terminal fibres against the daily brightening sky with such distinctness, that their curious intricacy of aspect, to a loving observer, recalls the appearances of some exquisite organism seen beneath the lenses of a powerful microscope, rather than ordinary objects seen in the open garden with the naked eye.

The herbaceous and other low-growing plants that bloom in

March must next be named; they are among the most lovely of the year, and, in contrast to the leafless or only budding state of deciduous trees, shoot forth their profusion of bloom from rich clumps of foliage. Hepaticas, red, white, and blue, double and single, form masses of floral jewellery wondrous and delightful to look upon. The hanging bells of the graceful Fritillarias, some speckled, some creamy white, are very charming in the subdued tones of their unpretending beauty; while the whole primulaceous tribe—Primroses, Oxlips, and Polyanthus—are seen in front of the shrubberies in such "lush" profusion, and sweet-scented Violets peepin such crowds from the shelter of their dark-green leaves, that even one untaught to the love of flowers cannot but stand and admire. But the best is not yet told. It is, after all, the Crocus tribe that gives the final touch of splendour to the garden borders all through March, for their "cohorts" are literally "gleaming in purple and gold." And, again, the Daffodil must not be forgotten. It was Shakespeare's favourite March flower, one that he especially marked out as a glorious denizen of the keen and windy month. I saw over thirty distinct kinds during last Ventôse, as the fanciful French reformers of the nomenclature of the months, named the gusty, blustering month of March, and not more than two of those thirty species were known to Shakespeare. Among them, pre-eminent over all the rest, rose the giant species, *Narcissus maximus*, throwing up a flower-stem two feet high, crowned with its splendid nodding bloom of golden yellow.

To this list of floral splendour in March must be added the many-hued tribe of Anemones, varying from pink stained white to crimson, and from a soft, pale lilac, to the deepest purple. Early Tulips, too, gaudy with yellow and scarlet, help to enrich a March garden, as well as Hyacinths, judiciously planted out; while the lawns assume a brighter and fuller green, as though to welcome the arrival of the first gay flowers of the year, many of which I have no space to describe in this hasty sketch.

This picture of horticulture in March was painted almost tree for tree and flower for flower from a very delightful garden at Edgbaston, a favourite region close to the great Warwickshire metropolis, where many a millionaire of Birmingham delights to make his *rus in urbe*, and generally knows how to do it with a rare taste and skill not always found so abounding in the suburbs of the greater metropolis on the banks of the Thames.

NOEL HUMPHREYS.

THE PARRAMATTA ORANGE GROVES.

PARRAMATTA, New South Wales, lies some fourteen miles west from Sidney, and is some sixty feet above the level of the sea. The first impression which fixes itself on the mind of a visitor to Parramatta is the English appearance of the town—the old cottages and pleasant gardens, the lofty trees, and the quaint-looking buildings. Attached to the old Governmental residence, is a park, now thrown open to the public, which is reputed to contain some of the largest Oaks in the colony. The soil in the immediate vicinity of Parramatta, though varied, is for the most part poor, and it seems difficult to understand how a tree like the Orange should flourish and thrive so well in ground apparently so incapable of affording it sufficient nutrition. Yet Parramatta possesses some far-famed Orange groves. In that owned by one gentleman, a military man, some of the trees are really magnificent, being close on thirty feet in height. They were planted nearly forty years ago, and are still yielding most abundant crops. They begin to give a crop after being planted for seven or eight years, and it is astonishing to see in what barren, rocky, unpromising-looking places the Orange thrives. Rock and sand are the characteristics of some of the plantations, and young trees are planted wherever a ledge will hold a little earth that the rains won't wash away. Piled up stones keep the soil together in places, but in many cases it looked as if the trees were growing out of the solid rock. Last year the crop of this particular grove, in a lump sum to a dealer, produced £2,000. This year the money produced will be much larger. Such glorious trees, their glossy green starred with hundreds of golden globes, the boughs tipped with snowy blossoms, and the air heavy with rich perfume, cause a delicious languor to creep over the senses while reclining beneath their cool and welcome shade. The freshly plucked fruit is delicious in temperature and flavour, and, of course, surpasses that which has been handled and packed for transport.

NOTES OF THE WEEK.

— The attention of visitors to the Inner Temple garden during the past few days has been attracted by the fine show of tulips displayed there, and which are now in full bloom.

— AMETENE, which is the product of a Californian tree, the Pinus Sabiniana, promises to take the place of spirits of turpentine in the arts, and to present many advantages over it. Mr. W. Wenzell, in the *American Journal of Pharmacy*, for March, has an exhaustive article on this new hydrocarbon.

— We would remind such of our readers as intend to compete for the prize offered by the Royal Horticultural Society for the best collections of hurtful insects, that the collections must be placed in the hands of Mr. Richards, the secretary of the society, at the offices, South Kensington, by the 1st of May.

— THE Earl of Shrewsbury and Talbot has consented to open the gardens of Alton Towers to visitors this year (commencing on Whit Monday, May 20th) on the following days: viz., for passengers by cheap excursions, on Mondays, Tuesdays, and Saturdays. For passengers by pleasure party orders, on Mondays, Tuesdays, Fridays, and Saturdays.

— THE centennial anniversary of American Independence will be celebrated by an international exhibition, to be opened in Philadelphia, July 4, 1876. Fairmount Park, Philadelphia, one of the largest and finest public parks in the world, has been adopted as the site of the exhibition. The buildings to be erected are to furnish fifty acres of floor space.

— THE Royal Parks and Gardens Bill has been reprinted after the discussion of it in committee. It now contains a clause providing that the park rules to be made by the Ranger or the Commissioners of Works, must be laid before Parliament, and if any rule be disapproved by either House within a month thereafter, such rule shall not be enforced.

— MR. W. J. EVELYN has signified his willingness to allow the towns-people of Deptford to use six acres of ground for purposes of recreation, a nominal rent only being charged. The ground is to the west of Old Sayes Court Farm, and, as it includes the site of the house in which Peter the Great lived while learning the art of ship-building in this country, it possesses some historical interest.

DOCTOR JULES GRAYOT, who died on the 31st ult., rendered great service to the cultivation of the vine in France, and was appointed to explore those departments which are almost entirely devoted to vineyards. His accounts of them, after eight years' experience, have been published, at the expense of the Government, in a work entitled "Study of the Vineyards of France."

— THE Palais Royal Garden cannon—one of the favourite sights of Paris—which on every fine day since 1786 fired off a charge of powder at noon precisely, the sun acting as artilleryman, was taken away two years ago to be repaired, and the nursery-maids and children who frequent the well-kept garden never expected to see it again. It was, however, restored to its place a day or two ago, and attracts as many meridian visitors as ever.

— NEARLY all the boundaries and divisions of land in Sardinia, says a correspondent of the *Times*, are cactus hedges, a mode of separation that could hardly be afforded in a country where land was more valuable and more extensively cultivated, since the cactus bushes push out their huge fleshy, prickly stems in all directions, cumbering and covering a great deal of ground. All the railway hedges are cactus; there are already some 250 miles of them; each one of the little bushes that compose them produces its ten or twelve prickly pears, and this fruit is a source of revenue.

— THE new East End Museum is 182 feet long, and is built in three spans or bays, each measuring fifty-two feet in width between the pillars. The site which it occupies is so ample as to leave not only a convenient space on either side and at the back for light and air at all times, but a handsome piece of ground in front, which is 330 feet long and 187 feet in depth. This land, enclosed by high iron railings—the standards of which are wrought, while the rest of the palisade is cast—will be ornamentally laid out, and will contain as a central adornment Minton's great majolica fountain.

— At a meeting of the London Court of Common Council on Thursday, a report was presented by the Markets Committee on the proposal to build a new market for fruit, flowers, and vegetables, in the City. It was proposed to re-construct Farringdon Market on an extensive scale, the cost of the undertaking being estimated at £150,000; and as there exists great necessity for a good and convenient fruit and vegetable market, the views of the Committee met with considerable support. The report was adopted, and it only now remains for the Committee to receive the sanction of Parliament and raise the sum requisite to carry out the improvements.

— THE 19th of April is especially set apart for tree planting in Nebraska, and the State Board of Agriculture urges upon the people the vital importance of tree planting, and offers a special premium of 100 dollars to the county agricultural society of the county which shall, upon that day, plant properly the largest number of trees; and a farm library of 25 dollars' worth of books to that person who on that day shall plant properly in Nebraska the greatest number of trees. Other States are doing likewise; that of Minnesota appoints the 10th of April as "Arbor Day."

— THE report of the progress of the Ordnance survey of London for the past year has been issued. It states that the plans of London on the scale of sixty inches to a mile are now complete. They are drawn on 326 full-sized sheets of paper, and probably form the largest and most complete plan of a city ever produced. Of these plans, 114 sheets have been engraved and published, and the remainder are in progress. The continual increase in the size of London and the alterations constantly made in it are so great as to make it highly desirable that arrangements should be made for an almost constant revision of the plans.

— SOME who have ascended the Beacon at Great Malvern, says Mr. Edwin Lees, in *Notes and Queries*, may be surprised to hear that the summit of the hill has been recently enclosed, and several ugly buildings erected there by a local speculator and photographer, for refreshment and photographic rooms, &c.; and I am told that even a croquet ground is to be laid out, thus utterly spoiling the natural aspect of the spot. It was always supposed that the greater portion of these noble hills, being included in Malvern Chace, could not be enclosed according to the compact made with the commoners by Charles I., whereby the king was empowered to sell one-third of the lands included in the Chace, and the other portion was to remain unenclosed for the use of the commoners for ever.

— METROPOLITAN Suburban cemeteries thirty or forty years ago were in the open country, but so rapid is the growth of London that there are few of them which are not now surrounded by houses; while some are actually situated in the midst of very populous neighbourhoods. Take, for example, the Tower Hamlets Cemetery at Bow. This already crowded burial-ground was but a few years ago separated from town by fields and market gardens; but London has overtaken it, and now streets of shops and houses surround and even extend beyond it eastward for several miles. The great cemeteries of Brompton, Abney Park, Dulwich, and Nunhead are also already outstripped by the builders; while even Highgate and the classic Kensal Green are manifestly doomed to be thus before long brought practically into town. The question, therefore, of whether the limits defined by the Burial Acts should be extended ought at least to receive the earnest attention of the Legislature.—*Times*.

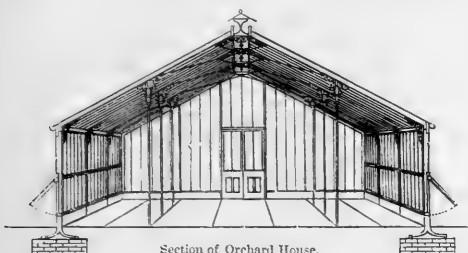

— WHATEVER objections may be entertained towards the appearance of Leicester Square, says the *Pall Mall Gazette*, it cannot be denied that it has one claim to admiration above all the other squares of London, inasmuch as it is the only square which is open to the public. The railings having been broken down in several places, children unattended by nurses, and by no means fashionably dressed, are admitted, or rather admit themselves, to the enclosure at all hours of the day and night, and find it a most convenient playground; indeed in its present condition it may fairly lay claim to be ranked among the "lungs of London"—a diseased lung, it is true, but nevertheless a lung, and one which is much appreciated by the youthful members of the lower classes. It behoves, however, all who use the enclosure of Leicester Square as place of recreation to show by their conduct that they are worthy of being permitted to enjoy that privilege. They should be especially careful to do no "damage" to any of the valuable shrubs and other attractive adornments of that hallowed spot! Above all, the remains of the statue should be treated with the tenderness and respect due to all that is left of a beautiful work of art. We regret to say that some miscreant has so far abused the confidence reposed in the public with regard to this treasure as to take away some of its fragments, which, but for the vigilance and activity of the police, would have been for ever lost. Michael Foley was the other day charged at Marlborough Street Police-court with having about fourteen pounds of lead in his possession, and not giving a satisfactory account of his possession of the same. Indeed, his account was most unsatisfactory, for having been seen by a police-constable to throw down the lead and run away, his defence when captured was that "seeing some children knocking pieces off the statue in Leicester Square, he took up a piece and walked away with it, not thinking there was any harm in doing so." The prisoner was remanded for a week, in order that inquiries might be made respecting him; and in the meantime let us hope that immediate measures will be taken to preserve the battered horse which, minus his rider and part of one of his legs, still prances proudly on his pedestal—a noble memorial of our respect for vested rights.

THE FRUIT GARDEN.

ORCHARD HOUSES.

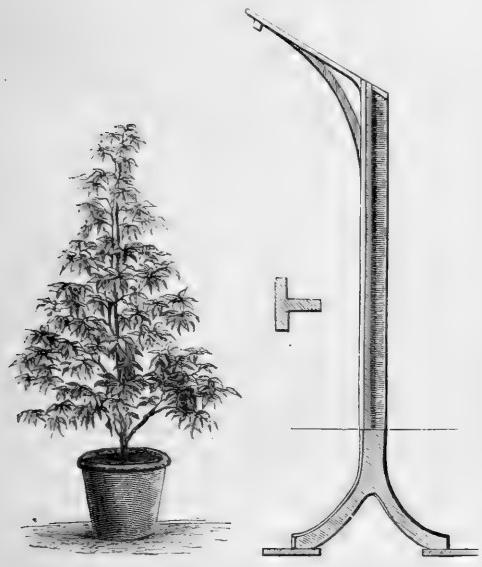

(Continued from page 105.)

In saying that double-roofed houses are as cheap as lean-to houses, I intended to say that a large number of square feet of land can be covered at as little expense by building a double-roofed house as by covering a wall already built. This, of course,

Section of Orchard House.

would not be true in the case of narrow houses. I had in my mind a house from twenty-four to thirty feet wide. A narrow glass case is a covered wall, not an enjoyable house. In calculating whether a house is cheap or not, I ask how much land it covers. This mode would not do for a builder, but it suits my purpose. The above woodcut will give a good idea of one

Young Pyramidal Peach Tree.

Iron Roof Support.

of my houses. The ridges, though a hundred feet long, lift with the greatest ease, by the same means as are employed to open the side-lights, i.e., a similar screw is used. A screw like this would lift a locomotive steam engine; and so easily does it work that lifts one hundred feet long can be opened with the point of the little finger. The house, as will be seen, is divided into four beds and three paths. Such a house is a garden under cover, in which ladies may walk and children

may play; not a low glass shed. All the bricks required in its construction are to form the little square blocks, on which the iron standards are placed. Their having a base of three feet, and standing ten feet from each other, gives enormous strength to the house. No man can shake them, nor can they be seen to tremble in the highest winds. Another great advantage of this mode of construction is that these houses can be made quite movable, instead of being fixtures, a great consideration in building on another's property. Those who want further information had better pay me a visit. With grooved rafters and glass curved on the bottom edge we have almost got rid of breakage from frost and drip. In the most stormy weather my last-built houses are as dry as a room. Nothing adds more to the appearance of such an orchard house than a vine trained up each pillar. Meeting at the top they give a beautiful arch of foliage and fruit; and as the pillars are ten feet apart, the shade is very trifling.

Opposite the openings, between the pillars, i.e., in the centre of the middle bays, standard Peaches and Nectarines are planted, forming two rows of orchard-like trees. Last year some of these produced as many as fourteen dozen fruit each of the finest quality. The rest of the house is occupied by trees in pots. Part of these dwarf trees might, of course, be also planted in the soil; but too many fixtures are a sad nuisance when the house requires painting. In choosing trees in pots, take care they are well formed, with strong bottom branches, or it will be difficult to get them to form such branches afterwards. In commencing with a young tree, called in the nurseries a "dwarf maiden," cut it down to five or six eyes above the graft, and make it grow like our illustration. This is by far the most natural form for the Peach. Any shoots that grow too fast can be stopped, and weak ones be allowed to grow; for nothing is easier than to make them assume this form, the advantages of which are obvious. The top does not shade the bottom branches, or the fruit upon them. If the top be allowed to grow wide, the fruit on the bottom branches is spoilt by shade, and the branches themselves become weak and unhealthy.

To save time, many Peaches are pinched in in the nurseries, and made to assume a pyramidal form before potting. This is a very bad practice. Not only are such trees often deficient in bottom branches, but what lower branches are formed are generally weak; besides which, the main stem of the tree having been formed out-of-doors is generally half-ripened, and often becomes unhealthy afterwards. The best soil for Peaches, and, indeed, for all fruit trees, is a good turfy loam; if of good quality, little or no manure will be required. Pot firmly, ramming the soil well down during the operation. Trees planted out should never have the borders either dug or forked afterwards; a loose soil encourages gross shoots, on which fruit will not set. When the soil of the borders is pretty dry, trample it as firm as a footpath, and keep it so. Nothing is more certain than that many Peach failures arise from loose soil.

I. R. PEARSON, Chilwell.

(To be continued.)

PLANTING OUT FORCED STRAWBERRIES.

WHERE strawberries are forced in quantity, the plants after being forced are planted out, if they are planted out at all, as an auxiliary plantation generally, without expecting either a great or certain return from them in the way of a crop, nor are they treated as if any expectations were entertained of them. The good things are reserved for what are usually called the permanent plantations, which do disappoint us often enough; but plants that have been forced the previous year, if planted out under ordinarily favourable conditions, may be relied upon to a certainty to produce, not only a crop, but a crop which for regularity and abundance will surpass anything that can be expected from permanent plantations. In bad years when strawberries have been a failure generally, I never knew the old forced plants to disappoint us, or any one else who tried them, the first year after planting. They are not to be relied upon a second year.

We have always planted out our forced plants in a systematic way every year, trenching the former year's lot down, and they

have always more than supplied our wants for all purposes. From one piece of ground, about thirty yards long by three yards in width, we gathered of Black Prince last year one hundred pounds' weight of good fruit, and we lost many by the wet, I could not say how many, but the wet weather delayed us getting any fruit for a long while. The plants from which this fruit was gathered were planted out the previous August, after a crop of potatoes had been taken off the ground.

Our usual plan is as follows:—As the forced plants cease bearing, they are moved out of the strawberry house and set in a sheltered corner, where they can be attended to and watered till planting-time. If the pots are needed, the plants are turned out and packed closely together, the interstices between the balls being filled up with any kind of soil at hand. We like to plant them out as soon as possible, but as a general rule, they have to stand as I have described till we begin gathering our early and second early potatoes, and the strawberries follow at their heels, getting them all into the ground by August. Plants which have been forced do not make such luxuriant growth as those which are planted out permanently, so we can afford to plant thicker. Black Prince varieties are allowed about one foot between the plants and eighteen inches between the rows; Prince of Wales and strong growing sorts a little more. In planting the balls of the plants are reduced sufficiently to disentangle the points of the roots, and they are planted as deeply as can be done without covering the heart. All the old leaves are cut off, and the plants always make a new growth.

Such plants always bear a fair crop the same season till late in autumn, if they are attended to, without, so far as I have observed, lessening the next year's crop. In spring the following year we mulch between the rows with old hot-bed manure, generally before the plants come into bloom, and when the fruit is set they receive a sprinkling of guano, which is washed down by the hose at once. After all the fruit is gathered the plants are trenched down, and winter spinach is sown in their place; this completes a routine of strawberry culture, which I have practised for many years.

J. SIMPSON, Worley.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Drainage for Fruit Trees.—It is useless, says an American paper, to talk about "fruit in a frog pond." We might as well expect our children to be healthy with wet, cold feet the year round as to expect fertility in our apple or other fruit trees in such a position. Drainage, either natural or artificial, and protection, are indispensable requisites of a healthy and productive orchard.

Injury to Fruit Crops.—I fear that fruit crops are much injured by the wintry weather which we experienced during last month, although it is too early to say to what extent. Apricots, I think, are gone; Peaches look bad; and also some kinds of Pears. Vines on a south wall here, which had pushed from half to three quarters of an inch, are all shrivelled up; and Goosberries are bad in colour.—W. DIVERS, *Weirton House, near Maidstone.*

Fertility of Oranges.—With regard to the prolific nature of the orange, the crops, more especially in an abundant season, are something really surprising. Twenty thousand marketable oranges from one tree seems almost beyond belief, but, as we have before stated, such is a fact; the branches have frequently to be propped up with wooden supports to prevent their breaking. Rissé mentions a tree growing at Nice in 1789, which was more than fifty feet high, and the trunk of so large a girth, that it required two men with outstretched arms to embrace it; this tree usually bore from five thousand to six thousand oranges.—*Food Journal.*

Thinning Fruits.—We do not thin our hardy and tender fruit nearly enough. Apples and pears are not often thinned at all, which accounts for the glut we have one year and failure the next. Standard trees out-doors are not, however, so apt to suffer from overcrowding as trees on walls and trellises, especially under glass. There is need for reform here, for it is common to see peaches trained so thickly as to thatch the trellis, to the almost complete exclusion of the light from a large portion of the foliage. Vines, again, may be seen with not more than six inches or nine inches between the rods, forming, when the summer growth is upon them, a hopeless thicket. It is the same in pine groving. "I like to have plenty of plants, and then I am always sure of fruit dropping in," is a common expression describing a most fallacious practice. Whether it be pines, vines, peaches, or anything else, the same lesson is taught, that crowding in any form is inimical to the production of good crops; and the same may be said of many other things connected with gardening. "What is worth doing at all is worth doing well," is a maxim which, if carried out in practice, will be found to be specially true in gardening.—S. W.

WALL FRUIT PRESERVED.

The fickleness of our climate has never been more strongly illustrated than within these last few weeks. Up to the end of February we had drenching rains and frosty nights, rendering the whole face of nature in many cases a huge skating ground; then, with the Thanksgiving Day, came a change, and for the first fortnight in March we had May weather; early varieties of fruit trees began to assume their spring garb, some plums in open quarters being a sheet of bloom, and now, the 20th of March, we have sunny days,

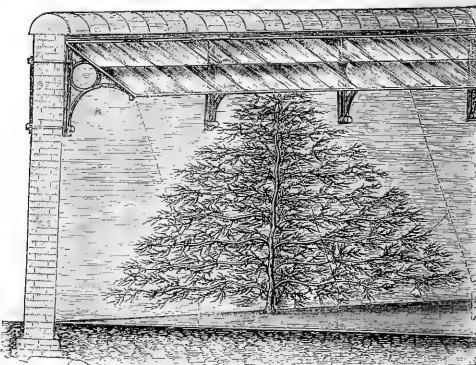

Fig. 1.—Glass and Iron Coping to Fruit Wall.

frosty nights, and dry March winds in all their bitterness. Fortunate is it that such is the case, for a continuance of mild weather, such as we had experienced, would in all probability have ruined our fruit crops. Security in regard to our more tender fruits therefore centres in the word "protection." Schemes of all kinds have been resorted to, from twisted

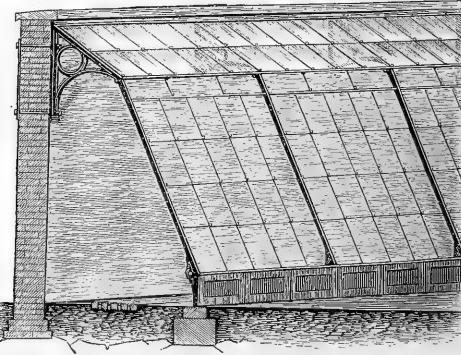

Fig. 2.—Coping converted into a Fruit Hous.

straw-bands, disused fishing nets, bunting of the most forlorn description, heavy copings of wood or masonry, down to makeshift glass shades, which, projecting but a few inches from the face of the wall, are, to say the least of them, most inefficient. What is worth doing at all is worth doing well, and impressed with this maxim, a gentleman noted for the growth of superior fruit applied to Mr. Ayres for assistance in devising some means of permanent protection, which, while it should be sufficient for that purpose, should not be an eyesore in the garden. The result is illustrated in the accompanying

design (Fig. 1), which is calculated to serve both for use and ornament. It will be perceived that it consists simply of ornamental cast-iron brackets bolted through the wall at certain distances apart, and connected together by parlines recessed to receive the glass, which covers it, and is held in position by metallic clips. These brackets project three feet from the face of the wall, over the trees which they are intended to protect; and this it is believed will be found amply sufficient for protection in the most severe seasons and exposed situations. But this is not all. Mr. Ayres' brackets are prepared to receive rafters, as indicated by the dotted line, so fixed on a centre, that should it be desired a house of any reasonable width may be added in the most simple manner. This is called the "expanding house," and as is shown by the dotted radiating lines, it may be expanded to any reasonable width; and not only that, the expanding part, when the crop is matured, may be taken away and used for any other purpose. Fig. 2 shows the addition merely as a glass case; and in Fig. 3 we see the preserver converted into a permanent erection—a fruit-house of the very best description. We need scarcely say this is a capital idea, the general utility of which will be at once apparent. Many may not be able to build a peach house, but most people can afford to fix their "fruit preserver," and if, a few years hence, there is a desire to add the house, there is the satisfaction of knowing that the necessary provision for that has been made.

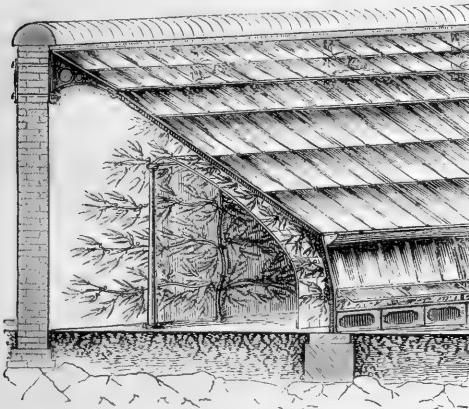

Fig. 3.—Expanding Fruit House.

Nor is this all; for, judged from a practical or scientific point of view, it is fair to infer that a glazed preserver projecting three feet from the face of the tree protected will, under all circumstances, husband sufficient heat to materially affect the early maturation of the crop; thus the house crop and wall crop may be brought closer together; and, by the same rule, the season of the wall crop may be advanced several weeks.

This we regard as an important point in connection with these fruit preservers, as they really appear calculated to answer the purpose intended better than anything hitherto introduced. Frost is said to descend, and if so, give us a wide protector, to prevent its falling upon the trees; but, in point of fact, we have nothing to do with frost. What we want is, to prevent the escape of heat; and as radiation is vertical, the wider a fruit preserver is—that is, the more it projects beyond the surface of the tree—the more likely is it to answer the purpose intended.

As permanent and slight erections, likely to answer the purpose intended, in the gardens of the wealthy, or to secure the cottage thefruit which will pay his rent, we recommend these fruitpreservers to general notice. They are manufactured by the Imperishable Hothouse Company.

THE FLOWER GARDEN.

NATIVE FERNS AND FERN CULTURE IN IRELAND.

The letters of your correspondents, giving accounts of the Devonian and Eastern Scottish Border ferns (pp. 376 and 457), suggest to me that some of your readers may care to have a like experience of the ferns which I have found growing wild in the "level plains of Kildare," and also some account of the ferns in an open fernery here. I shall begin with a list of the ferns which I have found in this county, and an indication of their special localities.

The Bracken.—Abundant everywhere.

Lastrea Filix-mas.—Abundant in all hedges.

Athyrium Filix-femina (*at least three distinct varieties*).—To be found plentifully in many parts, but in glorious abundance, vigour, and variety in the very peculiar locality which I shall describe further on when I come to Osmunda regalis.

Polystichum aculeatum.—Abundant in hedges and ditches.

P. aculeatum lobatum.—Abundant in ditches and hedges.

P. angulare.—Abundant in ditches and hedges.

Lastrea dilatata.—Plentiful on bog edges.

Asplenium Trichomanes.—Frequent on old walls.

A. Adiantum-nigrum.—Abundant in the hilly district towards the county Wicklow, and generally, though more sparsely, scattered through the county.

A. Ruta-muraria.—Abundant on old walls. In my own garden it peeps out plentifully through the peach trees, and is respected.

Ceterach officinaria.—Grows freely on the south walls of the ruined church of Bodenstown, and on several other walls; also on the bridge over the Liffey here.

Blechnum Spicant.—In any quantities on the hilly district towards Wicklow; also on bog edges.

Moon-wort.—I once found a single plant of this fern on a cut-away bog near Prosperous. I brought it home, and it appeared to take very kindly to its new quarters, pushing with great vigour the following year, but it was hardly well over the ground before a vicious slug [attacked it and sucked its heart's blood. I have got plants from elsewhere since, but the slugs seem so perfectly ravenous for this particular fern, that after trying various sorts of fences in vain, I have had to give up the attempt to cultivate it.

Adder's Tongue.—Abundant in moist meadows. I have frequently given plants of it to friends, who told me afterwards that they had subsequently found it in quantities at home.

Polypodium vulgare.—Abundant on walls and stumps of trees.

Hart's Tongue.—Luxuriant and abundant in all shady ditches; often bifurcated, and approaching to crested.

Cystopteris fragilis.—On the bridge over the Barrow at Monastereve.

Osmunda regalis and Lastrea Thelypteris.—I have only found these ferns in one place in this county; the latter I have never seen wild except here. Through a large tract of bog (a branch of the Bog of Allen, between Robertstown and Rathangan) runs a small stream; it has either formed for itself, or taken advantage of, a sort of shallow gorge through the bog of several miles in length, and varying from a few feet to twenty or thirty yards in width. This is cloathed with a coarse tufty grass, with here and there tangles of the bog-loving willows and bog myrtle. Let me one attempt to penetrate it who cares how high the black mud covers his trousers; but if any one wishes to see glorious specimens of Athyrium Filix-femina of very distinct types, the Osmunda growing in profusion, though not in great luxuriance, and the graceful Thelypteris struggling with the grass for mastery on every little tussock that lifts it a few inches over the semi-liquid mud, he will find them all there. I have spent hours in that happy valley.

This closes the list of the ferns that I have actually found growing wild in Kildare; but I have little doubt that Lastrea Æmula and Lastrea montana grow in this county, for I have found both in abundance in the adjoining county of Wicklow. At the Seven Churches of Glendalough, the latter is the fern. In the same county, as also in Donegal, Down, and Kerry, I have found the charming little Hymenophyllum, of both species. I have found this a most difficult fern to get to thrive in captivity; the Killarney fern is child's play to it. In the fernery here, a spray, as like that of a natural waterfall as may be, has been produced for the especial benefit of these two ferns; and the Trichomanes is behaving very decently, but the woodlice appear to take at least as deep an interest in, and to be far more unremitting in their

attentions to the *Hymenophyllum* than I am, the result being that every frond is denuded the moment it shows itself. I have had it do well under glass for several years, but even there it has always ultimately died off, apparently only because it chose to do so.

I cannot say that I have ever *found* *Trichomanes radicans* growing wild, but I have seen it in its native habitat in the Island of Valencia. I suspect that had I lived within a hundred miles I should not have been shown it. It has the name of being a difficult fern to cultivate, but I have not found it so. It is a *very* slow grower, the life of each frond being several years; but moisture, shade, and drainage are all that it requires. It has fructified in the glass case.

Asplenium marinum I have found at Dalkey, near Dublin, and in abundance in Valencia. I have never tried it in the open fernery; but planted on rockwork under glass, and without artificial heat, except for say half-a-dozen nights in the year, it grows luxuriantly here.

Polypodium Phegopteris I found in the Gap of Dunloe at Killarney, and also on the mountains over Tollymore Park, in the County Down.

Of British Ferns which I have not myself found growing wild in Ireland, but which are growing here in luxuriance in the open fernery, I may mention the following:—

Polystichum Lonchitis, *Asplenium viride*, *Polypodium Robertianum* and *Dryopteris*.

Cystopteris montana.—One of the earliest and most beautiful, now just spreading its fronds of freshest green.

Lastrea rigida and *cristata*.

Allotropa crispus I have, but cannot get it to thrive, though I have tried it facing south and facing north, planted in an open situation and almost buried under a big stone. Whether there is something in the position, or in the ingredients of the soil, that it dislikes, I have as yet been unable to discover.

Asplenium septentrionale is another that lived with me for several years, but each year sent up fewer and fewer fronds, till at last they disappeared altogether. Can any of your correspondents, who have cultivated these ferns successfully, give me any information about them?

I have not mentioned any of the varieties, but some of these are so marked as to bear little resemblance to their relatives, such as *Athyrium Filiix-femina Frizelliae*, *Polypodium vulgare cambricum* and *hibernicum*, *Polystichum angulare proliferum*, *Lastrea cristata spinulosa*, &c.

Of foreign ferns that are perfectly hardy, being planted out, and having no protection either winter or summer, I may mention the following:—

Adiantum pedatum.—A very lovely fern, delighting in moisture. *Struthiopteris germanica* sows itself everywhere about.

Onclea sensibilis.—Grown in a regular swamp, runs like a weed, producing quantities of tall showy fronds.

Cystopteris bulbifera.—A very free grower from the bulbs which form on the fronds.

Osmunda cinnamomea, *Lomaria alpina*, *Pteris candata*, *Cystopteris tenuis*.

Lastrea decursi pinnata.—Hardy, but capricious. I am misty about this fern, not knowing whether it is a species or only a variety, and if the latter, of what.

An old tool-house in a corner has had its slates taken off, and glass put on instead; rockwork has been piled up inside, and an abundant water supply provided; there is no artificial heat except one of Hink's petroleum stoves in very hard frost. Here the following British ferns thrive:—

Adiantum Capillus Veneris, *Asplenium fontinum*, *A. marinum*, *Trichomanes radicans*;

besides a host of foreign ones, for which this small amount of protection appears to make all the difference.

Millicent, Naas.

THOMAS COOKE TRENCH.

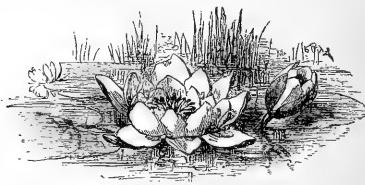

HARDY AQUATIC PLANTS.

THE WATER LILY.

This noble native plant is one of the many hardy subjects capable of producing the highest effects in our gardens, but to which we frequently fail to do justice. It is not enough to grow a plant, or to refrain from exterminating it, if a wild one. If the subject possesses any character, we should always

ask ourselves, is it so placed that we get the full expression of its beauty?

A well-developed plant or group of plants of the queenly Water Lily, floating its large leaves and noble flowers, is a sight not surpassed by any other in our gardens; but when it increases and runs over the whole or a large part of a piece of water, and thickens together and weakens in consequence, and the water-fowl cannot make their way through it without breaking pathways through the leaves, then even the queen of British water plants loses its charms. No garden water should be without a few fine plants or groups of the Water Lily, and

The Water Lily.

if the bottom be too poor to allow of the free development of the plant, scrapings or rubbish might be accumulated in the spot where it was desired to exhibit the beauties of Nymphaeæ. Thus arranged, it would not spread too much. But it is not difficult to prevent the plant from spreading; indeed, we have known isolated plants and groups of it remain almost the same size for years, and where it increases too much, reduction to the desired limits is of very easy accomplishment, either by cutting off the leaves or getting at the roots in the bottom.

The Water Lily is seen to greatest advantage in a small group a few yards from the margin of the water; but, isolated groups or single plants always look well, no matter where they are placed. It should also be remembered that small groups and individual plants always produce finer foliage and flowers when thus isolated than when crowded together. In many artificial waters the only way to get rid of the excessive growth of the Water Lily is by cleaning out the bottom. Where this is done, one can always leave a few roots or groups, and with each a good heap of soil, to encourage their growth.

THE CHILD-GARDEN.

FREBEL, whom we do not hesitate to call the greatest man of the nineteenth century, was not the first discoverer of the land of childhood, but he was the first who made a thorough exploration of it. The younger Fichte has recently declared that no man of this age understands human nature so well as Frederick Frobel. After a lifetime of labour as an educator and a reformer of education, Frederick, the head and leader of the "educating family," as the Frebels were called, founded the Kindergarten in his old age, the ripest fruit of a life wonderfully rich in ripe fruit. It was something very different from the so-called kindergartens in our cities, many of which are taught by persons who do not know what a real child-garden is.

Frobel started with the maxim, "The first work of a child is play." So far from repressing a child's playfulness, the wise man, who recognized God in nature, and God's law in nature's laws, declared that the *first work* of a child was to play. This is the business which his nature sets him about. This is God's ordinance for childhood. This is the supreme law of a child's nature. And it is the violation of this law which makes all our primary schools so pernicious. Play, according to Frobel, is not to be tolerated merely. It is to be encouraged, directed, and above all, laid hold of as the chief means of primary education. And so he devised the "child-garden." His own definition of a kindergarten was a "fore-school employment institution." He called all the employments plays, and all the materials gifts; and until the child was seven years of age he did not teach it so much as a letter of the alphabet. But in the kindergarten a child at seven finds all its perceptions sharpened, all its reflective faculties quickened, all its tempers harmonized, and its memory full of information acquired in a way so delightful that the health has not only not suffered, but the body also has been invigorated by the plays of Freebel.—*Hearth and Home*.

MODERN FLOWER GARDENING.

We have received the following letter from a nobleman resident in one of the home counties, and, as it expresses the sentiments of a good many lovers of gardening nowadays, we give it publicity:—

TO THE EDITOR OF "THE GARDEN."

DEAR SIR,—I havn't a notion of gardening, but am devoted to beautiful flowers. I have lately taken a small place in the country; there was no flower garden when we came to it, so I have had to make one. But, having laid out the beds as I think quite beautifully, I am at my wits' end to know what to put in them. I abhor the formal glaring borders that one sees everywhere, and have a sneaking fancy for what you call the "wild garden," only I don't quite know what it means. I have had the advice of many professional gardeners; but each new one appears to me a greater idiot than his predecessor, as all they can advise is so many thousand bedding-out plants. I hate bedding-out plants, and am sick of them; so I want you, if you will be kind enough, to recommend some one whom you think competent to give me really good advice on the subject.—I am, dear Sir, yours faithfully,

R.

[If you have committed yourself to a formal scheme of beds, a modification of the bedding system, with much variety, and a good deal of "sub-tropical plants" of the most desirable kinds will be best. Wild gardening is only fitted for the rougher and half-kept parts of the place—shrubberies, shady walks, grass walks, spots seldom mown, &c. As you hate "bedding out," endeavour to remove all formal geometrical patterns from the turf near the house, and give yourself an open, verdant foreground. Seek continually for beautiful hardy subjects of all kinds, from tiny bulbs to tall trees; and try to so group and otherwise arrange them, that they may, after being properly planted, prove a continual source of satisfaction. Isolated beds of such noble hardy families as the Lily are usually very beautiful; these will also grow nobly among your Rhododendron masses, if you have any. Pay great attention to Roses on their own roots and pegged down, not only growing these in beds, but boldly isolating strong plants on the turf, and in such a manner that no soil may be seen. Take many choice shrubs, such as *Spiraea Lindleyana*, out of the shrubby, where they are often neglected, and develop them into fine specimens singly on the turf, or group them with such noble subjects as *Yuccas*, *Pampas Grass*, &c. Numbers of fine shrubs are never seen in their best character, from the too common mode of planting them in serried masses. Every family of hardy plants should be searched for embellishments to grace the properly-arranged garden. Such classes of plants as the smaller ornamental grasses, Carnations, Picotees, and Pinks, Clematises, a good collection of climbers and trailers, and rock plants should be in every garden; and a good and properly-prepared mixed border for miscellaneous herbaceous and other plants is also indispensable, not necessarily instead of the more formal flower-beds, but as a charming adjunct them.]

CHAMALROPS EXCELSA.

A HARDY species, with an erect stem, twenty or thirty feet high in its native country, and dark green, erect, fan-shaped leaves, deeply cut into narrow segments. The leaf stalks are from three to six feet long, and are enclosed at the base in a dense mass of rough fibres, and armed at the edges with small, tooth-like spines. This palm is perfectly hardy in this country. A plant of it in her Majesty's gardens at Osborne has stood

out for many winters, and attained a considerable height. It is also placed out at Kew, though protected in winter. On the water-side of the high mound in the Royal Botanic Gardens, Regent's Park, it is in even better health than at Kew, though it has not had any protection for years, and stood the fearfully hard frosts of 1860. If small plants of this are procured, it is better to grow them on freely for some years in the greenhouse, and then turn them out in April, spreading the roots a little and giving them deep loamy soil. Plant in a sheltered place, so that the leaves may not be injured by winds when they grow up and get large. A gentle hollow, or among shrubs on the sides of some sheltered glade, will prove the best place for it.

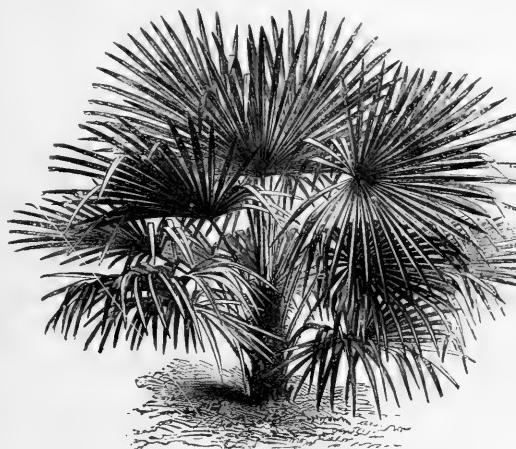

THE ROSE SECRET.

This, like most other secrets, especially gardening ones, is easily solved, and I am almost surprised that so shrewd an observer as my good friend and neighbour, Mr. Hole, should have been hoodwinked and tongue-tied by anything so flimsy. When, some thirty-five years ago, I assisted for a short time in the propagating-house of Mr. Rivers, we considered it no great feat to strike Tea, Bourbon, and Noisette Roses, from single eyes. These, taken off in a fresh kind of half-ripened state, and planted in sand under the usual conditions of a congenial earth heat and moist atmosphere, seldom failed to strike root and make good plants in the course of the season.

At one time, when experimenting upon the power of leaves to produce growing buds I frequently rooted independent rose leaves, but never succeeded in getting beyond that. Mr. Taplin has done a good deal to clear the mist from rose propagation; and to prove that the secret is rather an ancient one, I refer your readers to *London's Gardeners' Magazine* of about forty years ago, where they will find an article on the propagation of *Rosa odorata*, in which propagation from the growing wood in the spring is strongly advocated. As I quote from memory I am not sure who was the author; but if it was not Mr. Archibald Gorrie, of the Carse of Gowrie, it was Mr. Ellis of the Palace Gardens, Armagh. Though I cannot go into particulars, the facts are as fresh in my memory as if they had occurred only a few months ago.

With suitable appliances to strike roses in the early season in the growing state, the same in July and August, and later on in the ripened state, is not a difficult matter. But we must recollect the conditions under which the cuttings have been produced; for to take cuttings from heat to cold would be just as absurd as to take them from the open air and expect them to strike in a strong bottom heat. These are the points, more than any other, upon which inexperienced propagators fail, more especially with plants that are in any way disposed to be hard-wooded. Take cuttings of Roses any time in September, before the frost has touched them, and cutting them into lengths, insert them in loam, either in pots or a cold frame; protect them from severe frost through the winter, and by spring you may fairly calculate that a very large proportion of them will be rooted plants. If, however, quantity, and strong plants in a short time be the object, then bud grafting upon the Manetti stock or briar is the royal road to quantity. Buds can be rooted as independent plants in the soil, but not so quickly and surely as they can upon a healthy, well-established stock. I say nothing as to the desirability of the two systems. Plenty there are who grow the Rose admirably upon its own roots, others are equally successful with the Manetti stock, while I think great Rose-growers themselves pin their faith, for show purposes, to the British briar in its second season, a good deep loam, and no "tightness" in the manure market.

W. P. A.

The Hardy Palm (*Chamaerops excelsa*).

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Dwarf Yellow Wallflower (*Cheiranthus praecox aureus*).—This charming little plant, growing only about six or eight inches high, is now in bloom around London. It is of a compact and stubby habit, very sweet-scented, perfectly hardy, and of a bright yellow colour. It is most valuable for the spring garden, the mixed border, and also for naturalization in rough rocky places with the common kind.

Delphinium formosum, *Phlox Nelsonii*, and *Iris reticulata*.—Two or three little points struck me as I went through your work on "Hardy Flowers"—matters personally known to me. First, *Delphinium formosum* is a garden hybrid, although it reproduces itself from seed as truly as most species. It was raised by the late Mr. C. Moore, nurseryman, East Dereham, in this county. Second, *Phlox Nelsonii* is also a garden hybrid, between *P. frondosa* and *P. nivalis*, raised about twenty years ago by my late father, who was rector of Winterton, also in this county. Third, *Iris reticulata*: my soil may be described as a strong loam, with a brick-earth subsoil not eighteen inches from the surface, and here it thrives amazingly in all positions on the level. A friend gave me about a score of roots ten years ago; I have exchanged and given away since that time more than three hundred, and have now a stock of at least five hundred—all from the original twenty roots. Moreover, I have never seen it do as well anywhere where the soil is lighter and warmer. It does not seed freely with me, though many abortive seeds are formed; but this year I have about twenty seedlings from seed saved last year.—J. G. Nelson, Allborough Rectory, Norwich.

THE PROPAGATOR.

ON PURE HYBRIDIZATION, OR CROSSING DISTINCT SPECIES OF PLANTS.

BY ISAAC ANDERSON-HENRY, ESQ., F.L.S.*

The following are the rules I observe and the means which I take to insure success in my experiments with reference to this subject:—

1st. I long held it to be of vital importance to have the separate plants intended for the parents in the cross, even though both were hardy, put under glass, and I still recommend it; for, by doing so, you heighten the temperature—an important thing—and you can better secure against the interference of winds and insects; and though Darwin holds the former of small account, I have reason for differing from him there. But in the height of summer pollen may be taken from an outside plant to cross an inside one, and vice versa. If the cross is to be made on an outside plant which cannot be conveniently removed, I cover it with a hand-glass or cloche.

2nd. I hold it not enough merely to emasculate the intended seed-bearing flower; I take off every petal, for the petals attract the insects, which seem guided more by their optics than any sense of smell. This act of emasculation in some cases I perform long before the expansion of the bloom; for in many plants—e.g., in the Papilionaceæ, some of the Rosaceæ, and Composite—self-fertilization may, and does, often take place in the unopened flower. This is not all. Isometimes put a gauze bag over it; if I do not, the mutilated bloom may not escape that most troublesome of all insect pests, the humble bee, which in his unwieldy flight, may come across it by pure accident. But for the most part now I make clean work of it, and remove all other expanded flowers on the seed-bearing plant, and allow no kindred one to bear.

3rd. Do not be in a hurry to effect your cross; wait till you find that the stigma is fully developed. In many plants this is shown by a glutinous exudation on the summit, as in the Ericaceæ, the Onagraceæ, &c. In other orders, such as the Geraniaceæ and Malvaceæ, it is indicated by the featherly expansion and recurvature of its separate divisions.

4th. The next thing is to obtain properly ripened pollen grains from the male plant. This is done by carefully watching when the anthers burst, otherwise the insects may be before you; and so active are they, especially on such favourite food as the pollen of the Rubus tribe, that, to get it at all, I have found it necessary to encase the opening blooms in muslin bags till the pollen was ripe, and ready for use. Do not use, as is generally recommended, the camel-hair pencil, which, applied often and indiscriminately, may, and often does, convey, with the foreign, some insidious grains of

* A paper read before the Botanical Society of Edinburgh, and since revised and added to by the author.

native pollen, which, however few, are prepotent, and wholly neutralise the former. Take, where that can be obtained and afforded, the entire bloom of the intended male, and give the slightest brush with all its anthers over the stigma, or all the stigmas, if more than one, of the intended female. I will give my reasons for this by-and-by. You may use for experiment, in some cases the long, and in some the short, stamens. To those of the proper dimorphic form I have made some allusion elsewhere; they occur in the species of *Primula* and in some of the species of the *Linum* tribe (as to both of which, see Darwin's most remarkable papers in the Proceedings of the Linnean Society). Such anthers, at least two long and two short ones, occur in the two orders of the Linnean class Didynamia, on which I may have a suggestion to offer hereafter, for I think something interesting may be worked out of this form. In cases where the anthers are few, as in the Linnean classes Diandria, Triandria, &c., you may use small pincers—a bit of wire so twisted as to form that implement, to carry in the pocket, is by far the handiest. I have used such an instrument all along, and find it better than any other form. In some tribes, the better to secure against invasion by insects, such especially as in some of the Rosaceæ having large discs, a muslin bag may be used, so as effectually to exclude them; I use it constantly in the Rubus tribe immediately after emasculation, taking it off and replacing it after the cross, and keeping it on thereafter till the cross has set.

5th. In some cases it is a matter of some difficulty to procure, and when procured of no less importance to preserve, pollen. In dioecious plants—say the *Ancuba*—a friend may have the male and you have, as we all have, the female in abundance. You would like to store that pollen till your female plant, generally later, comes into flower. Many hold that pollen cannot be preserved in a vital condition for more than one or two, or perhaps three, weeks. In a recent publication which refers to this matter, namely, Max Wichura's "Observations on Hybridization," of which a very lucid abstract, carefully digested and translated from the original German by the Rev. M. J. Berkeley, is given in the January number of the *Journal of the Royal Horticultural Society*, that eminent authority holds it as "a fact of great importance that the pollen of willows retains its potency for some time. In some cases pollen ten days old was efficient, while vitality was still further prolonged by steeping it in a solution of honey" (of which I have doubts). "Pollen," he adds, "of *Salix Silesiaca* eight days old seemed 'almost as potent as ever'; in twenty-eight days the traces of vitality were very slight, while that of *Salix cinerea* had become weak in sixteen days." Now, I am not aware that there is less vitality in the pollen of willows than in that of any other family, and, as many experimentalists hold kindred views to those here enunciated by Wichura, I deem it a matter of some importance to give you one or two instances of my own experience. I have carried in my pocket the pollen of Rhododendron again and again from six weeks to two months and upwards, and still found it potent. Of the Japanese forms of the genus *Lilium* I have kept pollen effective in the same manner for equal periods. In fact, generally speaking, I have found the pollen of most plants to remain good for similar periods. Having last year got the new and beautiful *Clematis Jackmanii* to flower, and anxious to preserve its pollen as long as possible, I collected and stored it in its anthers in a simple pill-box. On the 4th of July 1866, I so gathered and put it into a drawer of a cabinet in my own sitting-room, where it remained wholly away from damp. On the 5th of June 1867, having first carefully emasculated a flower of *Clematis candida*, I crossed it with the pollen, then eleven months old, and from this cross I have this autumn gathered and sown eight well-developed seeds. Now, both parents are hybrids, with a large infusion of alien blood in them, so that here the vitality was put to its severest test. Subsequent experiments satisfy me that the vitality of all pollen may not be so long preserved, for I have found that of the *Ancuba* inert after being stored about six weeks. But as some bits of stems had got mixed, these may, by inducing damp, have destroyed it. I would therefore recommend it to be brushed off pure and stored in silk paper. I notice this result here (somewhat out of place) to suggest the propriety of storing, and, if needful, of importing, pollen, which, if wrapped up in silk paper, might even, enclosed in a letter, reach this country still potent, by the overland route from India, or, after two or three months' voyage, from all parts of South and North America. Let collectors and friends in distant countries be instructed as to this, and we may soon have an improved progeny of the rarest things, even before such novelties from which they are derived have been obtained from their own seeds in this country.

6th. There is another matter of much consequence to be attended to in the crossing of distant species; I mean the times and seasons for effecting the cross; yet not one of those most experienced in the art, from Darwin downward, has touched upon this point. It has been forced upon my attention for more than twenty years. I

have found that I could, on some few propitious days which occur throughout the season, successfully effect crosses I could not effect with all my care at other times. I have adverted to this in the paper I formerly submitted to you, and I again refer to it. There are some crosses which I have effected at such times, and which I would have tried in vain to accomplish at times less favourable. If you have, say, two plants of Rhododendron, one a tiny thing, to cross with a large species, or if you wish to attempt a cross between an Indian azalea and a rhododendron, watch for a propitious time. Such times occur, often few and far between, when there is less of sun than of that latent form of heat, which frequently occurs before thunder, from the air being more than ordinarily charged with electricity. Or they may occur in the spring season, when there is much ozone present, whose influence I have often found to tell most favourably in promoting the germination of long-sown seeds. It was to the presence of ozone, or to some other form of electrical agency, I attributed the almost simultaneous germination of some New Zealand seeds of a shrub which I got from that country under the name of "Black Maupan," a species of Pittosporum, which sprang up together on the morning of the 16th March 1863, after they had lain dormant two years and eight months. Such atmospheric conditions, to whatever cause they may be due, I have found not unfrequently to occur with the east winds of March and April; at which times I have seen many other long-sown seeds spring quite suddenly and unexpectedly. Seize upon all such seasons for difficult crosses. As to the time of the day, you may operate best perhaps from ten a.m. till six p.m.

(To be continued.)

PROPAGATING SOFT-WOODED BEDDING-PLANTS IN SAND AND WATER.

Not recollecting to have seen this mode of propagating bedding-plants notified in your pages, I have thought it might prove useful to some of your readers—amateurs especially—to know that, in comparison with the customary modes of "striking" such subjects in pots, &c., in soil and sand, the way now indicated possesses greater simplicity and despatch, while it also reduces to a minimum the "damping off" contingency, incidental to the old mode. Having now for several years pursued the plan in question with uniform success, more especially with such plants as Verbenas, Petunias, Ageratum, Coleus, Iresines, &c., I can recommend it with the greatest confidence.

My *modus operandi* is to fill with moist silver sand common flower-pot saucers, or other suitable vessels; insert the cuttings thickly with the peg, fill up with water, and place the vessels on a shelf or other suitable site in the propagating pit. Shading from the sun I am not fastidious about, so long as the pans contain a sufficient amount of water. As soon as the cuttings have formed a mass of roots, which only takes a few days to effect, I transplant them into boxes or pans of light soil and leaf mould, replace them in heat for a few days, and afterwards gradually harden them off in some cool structure. The pans of sand may be refilled with cuttings repeatedly *ad infinitum*. WM. GARDENER.

Lower Ealington Park Gardens, Stratford-on-Avon.

MAKE-BELIEVE GRAFTING.

THERE is a Rose tree in the Botanical Garden at Ghent, where it was produced by M. Donkelaar, which flowers extensively each year in the midst of an Oak, which causes it to be called by the uninitiated the Oak Rose tree. On first seeing it, it has quite the appearance of being grafted. We think it may prove interesting to show what extent artifice can be carried. A young Oak was taken, of two or three inches in circumference; by means of a red-hot iron, a hole was bored the entire length of the centre of the trunk, and through this were passed the roots of a young Rose tree. The two plants thus formed into one were potted, and the hole round the extremity of the Rose tree was stopped up. The plant was taken good care of, and it flourished and flowered as though nothing unusual had happened to it. But is this really a graft? By no means, as there is not the slightest union between the two. They are two plants, each having its own roots, struggling and disputing between themselves without ceasing for nourishment, and living not one for and by the other, but separately, the one in the other, until the weaker is strangled by the stronger.—C. Patin.

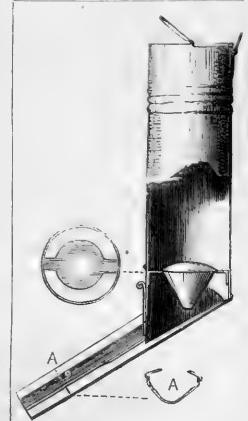

PROPAGATION OF THE IPECACUANHA PLANT.

The following method of propagating this important officinal plant has been communicated to the Botanical Society of Edinburgh by Mr. McNab:—"The Ipecacuanha plant (*Cephaelis Ipecacuanha*) has recently been attracting much attention, from the belief that it will become, like the Cinchona, a profitable plant to cultivate in various districts of India. The *Cephaelis* *Ipecacuanha* is a native of the moist woods of Brazil, and was first introduced into British gardens in 1830. It is a plant of remarkably slow growth. The largest now in the Botanic Garden is scarcely one foot in height, although more than thirty years of age. The method hitherto adopted for propagating the *Cephaelis* (as far as I am aware) is by cuttings, but of those not more than one or two can be got at a time, and at very long intervals. By this slow method of propagating the *Cephaelis* must always remain exceedingly rare. The roots, or rather rhizomes, of the *Cephaelis* are moniliform or annulated. A few of these were taken from one of the plants in the Botanic Garden during the month of August 1869, and after being cut into small transverse sections, they were inserted in a horizontal position over the surface of a pot prepared with drainage and white sand. This pot was placed under a hand-glass in a warm propagating bed and kept moist. A few weeks after, the bits of roots showed buds on the upper side, roots being also sent out from the under surface. The plants are now beginning to grow, each being furnished with two leaves, the largest measuring three-quarters of an inch over. In order to meet the demand which, in all likelihood, will be created for plants of the *Cephaelis*, it is well to know how it can be propagated independently of cuttings, and at the same time without injury to the parent plant."

TOOLS, IMPLEMENTS, &c.

THE SIDNEY GARDEN SEED SOWER.

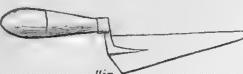

We have had this apparently very useful little contrivance properly engraved in order to show the way in which it is constructed, and also for the purpose of exhibiting a recent improvement carried out by its inventor, Mr. Cox. This consists in the introduction of the little inverted cone in the middle, which prevents largish seeds from forming an arch, and consequent stoppage, at the base of the upright or main tube. Our woodcut indeed explains the matter so clearly that nothing farther need be said in reference to it. All sorts and sizes of vegetable and flower seeds can be sown in drills, or even broadcast, in any required quantity, by regulating the slide. It is useful also for dusting with tobacco powder to destroy aphides; likewise for dusting sulphur over plants to kill mildew. It will, in short, prove a welcome addition to our stock of handy garden tools and implements. The small size is that best calculated for sprinkling tobacco powder, &c., over plants. The Sidney garden seed-sower is made in several sizes.

Sectional View of the Sidney Seed-sower. The Sidney garden seed-sower is made in several sizes.

THE BEST KIND OF GARDEN TROWEL.

The common concave garden trowel is a worthless implement, effective chiefly in wasting time. From its shape the earth clings to it much more than to a flat trowel; it is generally of bad

material, and its concave shape presents no advantage whatever. This shape is given it because it makes a roundish hole; but, as every person with any practice in planting knows, a precise shape

for the hole is of no consequence whatever. The object is simply to make one deep enough and large enough in the shortest space of time, and with the least labour possible. This is best effected by the trowel we now figure, and which we have used for some years; once accustomed to it, one would almost as soon use a piece of an old flower-pot as the common garden trowel. It is of the best steel, and is marked with a crown and W. H. Another reason why a straight form of trowel is preferable, is that the great majority of small plants should be planted against the side of a small cut—a little trench with one firm, straight side, for the making of which the concave trowel is of course much less effective than the one here spoken of.

THE TOOL HOUSE.

The common hoe is perhaps the most troublesome small garden or farm implement to hang up in the tool-room, out of the way when not in use, and still exactly in the way, and so as to be always handy when we want it in a hurry. Vexation is increased at a fearful ratio

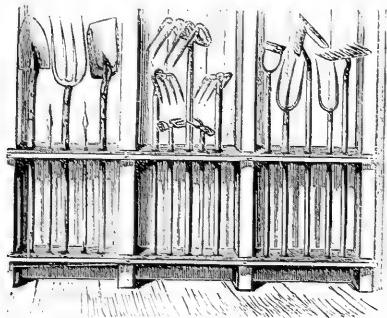

Fig. 1.

if you have a dozen of them. The floor of a tool-room should be kept as free as possible from all obstacles to the sweep of the broom. Very likely in a new room you will hook the hoes over the edge of the plate, or some gilt or horizontal timber in the framework, and

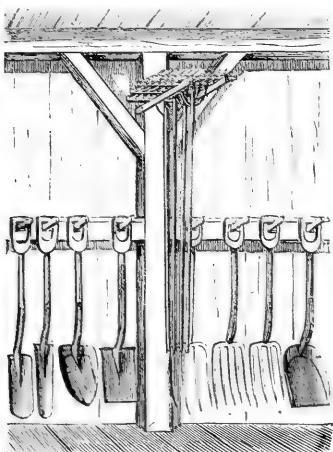

Fig. 2.

think they are nicely fixed. The first time you look for your favourite weapon, two or three others are on top of it, and their centre of gravity is so awkwardly poised that in selecting the one you want you fetch them all clanging down about your ears. A lath

nailed across the upright studding is a little better, but not satisfactory. After many trials I have settled upon this (fig. 1) as the best way to dispose of that large class of implements with straight handles, to which hoes belong.

Upon the wall of the tool-room, within about six inches of the floor, affix a strip of inch-board, five inches wide, shelf-wise. Let this extend twice as long as you think at first you will need, for it is astonishing how the mop sticks, and broom handles, and unfashionable utensils, that you are not quite ready to fling away, will gather upon you when once you have a place to put them. This narrow shelf should have inch-holes, six inches apart, sunk along its centre, through its entire length, bored half-way through the board. Also holes rather smaller may be bored midway, near the edge of the shelf. Above this shelf—say two feet—affix another, six inches wide, with corresponding holes clean through it—the inner ones one-and-a-quarter-inch, and some of them one-and-a-half-inch, for larger handles, the beetle, or the iron bar. If slots are cut in the back edge of each shelf, many things will find a place there, where they will always be in sight and never in the way. The iron wedges, for instance, near the beetle; odd strap hinges and bits of iron or wood, that will be sure some time to be used if where they can be seen in time of need. Such tools as hoes, potato-hooks, garden-rakes, long-handled shovels, spades, forks, and the like drop into their places at once, and they will stay there. The half-hole in the bottom shelf keeps them steady. Shovels, spades, and dung-forks with short handles are well hung, concave side to the wall, upon stout wooden pegs, set in a strip of one-and-a-half-inch stuff cleated to the wall of the tool-room or stable, as shown in Fig. 2.

How to fix pickaxes and mattocks so that a workman coming in tired, with a back-load of tools, would be glad to put them in place,

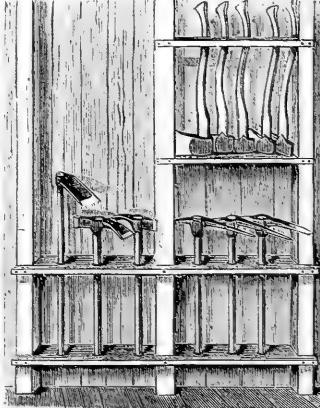

Fig. 3.

did for a while bother me. I finally fell upon the plan described for hand-hoes, making the holes larger, and the upper ones of an oval shape, diagonally, by boring two holes close together with a two-inch auger. Choppers' axes come in well between two studs (fig. 3), resting the head of the axes askew upon a narrow shelf, breast-high, and holding the helms upright by a cleat two feet higher.

Having tools arranged in this way, with variations according to individual fancies or necessities, leads to a precious saving of time and trouble.—*Burton Briggs, in "Hearth and Home."*

THE SOURCE OF GREATNESS.

If we were to be asked abruptly, and required to answer briefly, what qualities chiefly distinguish great artists from feeble artists, we should answer, I suppose, first, their sensibility and tenderness; secondly, their imagination; and thirdly, their industry. Some of us might, perhaps, doubt the justice of attaching so much importance to this last character, because we have all known clever men who were indolent, and dull men who were industrious. But though you may have known clever men who were indolent, you never knew a great man who was so; and, during such investigation as I have been able to give to the lives of the artists whose works are in all points noblest, no facts ever looms so large upon me—no law remains so

steadfast in the universality of its application, as the fact and law that they are all great workers; nothing concerning them is matter of more astonishment than the quantity they have accomplished in the given length of their life; and when I hear a young man spoken of as giving promise of high genius, the first question I ask about him is always—does he work? But though this quality of industry is essential to an artist, it does not in any wise make an artist; many people are busy, whose doings are little worth. Neither does sensibility make an artist; since, as I hope, many can feel both strongly and nobly, who yet care nothing about art. But the gifts which distinctively mark the artist—without which he must be feeble in life, forgotten in death—with which he may become one of the shakers of the earth, and one of the signal lights in heaven—are those of sympathy and imagination.—John Ruskin.

THE INDOOR GARDEN.

THE GOMUTI PALM.

(*ARENGA SACCHARIFERA*.)

This is the Sugar Palm of the Indian Archipelago, where it is very useful to the natives, producing sago from the pith of the stem; and from the flower-stalk is obtained a juice of which sugar is made. The leaves are also found to be useful for thatching, and the leaf-stalks make rafters for huts. From the coarser fibre produced at the base of the stem are made brushes, while the finest is used for studding

The Gomuti Palm.

cushions. It is one of the largest of palms, the fronds being often twenty feet in length. When it has attained its full height, it begins to flower from the top downwards. The male and female flowers are borne on separate plants, and are produced in great quantities. It is a fast-growing palm, and is quite out of place in a small house. There is a fine example of it in flower in the Palm House at Kew. J. CROUCHER.

CULTIVATION OF CACTI.

BY J. CROUCHER.

The majority of Cacti are sun-loving plants, and, as a consequence, the first thing to be taken into consideration is to get your house so situated as to insure the greatest amount of direct light, therefore the best aspect will be due south; a lean-to house is the best, with good clear glass, to which the plants must be as near as possible. The genera Epiphyllum and Rhipsalis are exceptions to this rule, and prefer a little shade in the summer, as they mostly grow in the forests, but in any house there are always some parts more in the shade than others. The plants are not damaged by the sun but will grow more luxuriantly in the shade. It is not easy to get the house too hot for Cacti in the summer, but they will thrive well in a temperature of from 60° to 80° with sun, and in winter the majority will bear a minimum of 40° with dry air; though the genera Rhipsalis and Epiphyllum must be kept at 55° to 65°, or they will protest by looking very yellow. As most of these plants are natives of those parts of America lying south of the equator, they, as a consequence, get their warmest season when we get our coldest, which gives them a tendency to grow during our winter; and a predilection for rotting, if not kept perfectly dry.

POTTING, SOIL, ETC.

As above stated, these plants being American, they should not be repotted in early spring, as is the common practice; which practice seems to have originated from the fact of most plants starting into growth on or about that time. I have often thought, that if amateurs and gardeners were to think more on this subject, they would at once see the folly of supposing that all countries had their spring at the same time as we have in England; it matters little with most persons if the plants come from east, west, north, or south, they must be potted in our spring; and as the plants will not grow out of their season, the soil gets stale, and when the roots do begin to grow, they find the condition unfavourable, and the result is stunted growth, and sometimes death; not through a wrong compost, but unseasonable potting. The potting of Cacti should be left until June or July, when they will be on the point of starting into growth. The best compost is loam, with silver-sand and broken bricks, the quantity of sand must be regulated by the stiffness or otherwise of the loam; the object being to make the whole sufficiently porous for the water to pass through freely; as a rule one gallon of sand to three bushels of loam, and one bushel of finely-broken bricks will suit for the genera Opuntia, Echinocactus, Echinopsis, Cereus, and Mammillaria; for Epiphyllum and Rhipsalis, a mixture of rough peat and loam, with a little sand and rough crocks, is the best. Such as R. Cassutha, funalis, sagittaria, and mesembryanthemoidea may be grown on pieces of fern stems, in baskets or pots suspended the same as orchids, and very interesting objects they make; Cereus flabelliformis and leptipes succeed best suspended in a pot, with the ordinary soil; C. grandiflorus, Macdonaldiae, and the other night-flowering species, grow best planted in the back border of a stove with a tolerable amount of moisture in the air; it is not necessary to give them much soil, as they get most of their nourishment from their aerial roots. When the plants are to be potted, the whole of the small fibres of the roots should be cut off; this is a very particular point in the cultivation of this class of plants, as it enables you to get the plants into small pots, and if left on they decay, and so do more harm than good, by making the soil impure; amateurs, as a rule, are very shy at cutting the roots from their plants, but a good cultivator of Cacti has not the least hesitation about the subject; and it is probable that they lose most of their fibrous roots during the dry season in their native habitats. The soil should be made quite firm in the pot and well drained; taking care to put enough rough pieces of soil on the drainage to prevent the soil from getting amongst it, and so defeat the object for which it is placed there. Manure should be specially avoided, as it will cause the soil to get charged with impurities with the least excess of water, which impurities the plants will take up, and though they may look green and healthy, may some day be found quite dead; some persons recommend manure, but after sad experience, I say away with it. I also know persons who grow their plants in nearly all manure, but they are grown for sale, and their profit consists in the death of the same. Others again recommend lime rubbish being mixed with the soil; which practice has originated from the fact of oxalate of lime being found to constitute a great portion of the substance of these plants; but lime rubbish from the débris of old buildings is very different from that found in the natural soil of the plants, and the effect on the roots is to cause them to become stunted, and what horticulturists call "clubbed"; therefore my advice is, if you want your plants to grow well, don't use lime rubbish.

WATERING, ETC.

When the plants have been potted, they should be kept without water until they show signs of growth; never mind if they don't

ask for it until two or three months after potting; don't give it them until they do, for they always contain enough moisture to enable them to start; and until that start is made, the roots have not begun to grow. When the plants have started into growth they may be watered about once a week for the first month; after that twice, with a good syringing every other evening before shutting the house. This treatment may be continued until the end of August, when the syringe must be laid aside; after September, the watering must not be oftener than once in fourteen days. From October till March, the genera *Mammillaria*, *Echinocactus*, *Cereus*, and most of the *Opuntias*, must be kept quite dry. As the *Phyllocacti* flower in the early spring, they must get water about once a month during the winter. *Epiphyllum* and *Rhipsalis* may be moderately dry; but they will not endure so much drought as their more succulent allies. It is not necessary to pot the plants every season, as they like to be pot-bound; some do well in the same pot for five or six years. Should any plant be found to have lost its roots, or show signs of decay, the infected part should be cut clean out at once, and the plant turned up to the full power of the sun, till it begins to show fresh roots, when it may be repotted, and watered with care. This rule of turning the plants up to the sun should be especially attended to with newly-imported plants, as they require all superfluous moisture cleared from them; their roots should be cut off, as when dead they act like string, conducting moisture to the plants. To the neglect of cutting off the dead roots I attribute the many failures to grow the Turk's Cap cactus (*Melocactus communis*); although this species evidently does not increase in size after forming the cap or flowering point, yet it may be kept alive some years.

MODES OF PROPAGATION.

The genera *Rhipsalis*, *Phyllocactus*, *Cereus*, and *Opuntia* are easily increased by cuttings, which should be taken off in May, and laid in the sun until rooted, when they should be potted and watered carefully, though *Rhipsalis* and *Phyllocactus* may be potted at once, and kept dry about fourteen days, when they will be rooted, and may be watered; *Echinocactus* and *Mammillaria* must be increased by offsets; *Echinocactus* requires the top to be cut off, which must be exposed to the sun until rooted, the old plant will throw out young ones, which may be taken off the next season. As a rule, the *Echinocactus* is slow in throwing offsets, and care must be taken not to let the plant get any water until it shows signs of doing so; patience is a virtue in great demand in the propagation of this section of the order. The slender-growing species are often grafted on stronger and faster growers, though care must be taken not to select for a stock one as celebrated for vigour as the scion is for want of it, or your labour will be in vain. As a stock for the smaller-growing *Echinocacti*, *Cereus tortuosus*, or *colubrinus*, are the best; for the larger, *C. peruvianus* and *geminatus*. In grafting, care must be taken to cut the two ends rather convex than concave, as they are apt to shrink a little, which would cause a separation, and so spoil the graft; the scion must be tied firmly to the stock, taking care that the edges meet, or, at least, one of them; the best plan to insure against accidents is to put three sticks into the pot, and tie them together above the plant, thus causing a continual pressure from above. In grafting *Opuntia clavarioides* you may cut a cuneiform notch in the stock, and cut the scion to fit tightly, keep them firm with a stick on each side and a thorn run through the graft. Some of the smaller species of *Cereus*, as *C. tuberosus*, may be made pointed, with a corresponding hole in the stock; in all cases taking care not to disturb the plant when once grafted. When the operation is finished, the plant must be put into a close frame, or the shadiest part of the house, until it is out of danger. *Epiphyllums* are generally grafted, but not necessarily. The common stock used is *Peregrina grandiflora*, and *Bleo*, but *Cereus speciosissimus* and *triangularis* make very good stocks, these plants being stouter, and more in proportion to the scion, though *Peregrina* stocks are more to be depended upon than *Cereus*. Cuttings of *Peregrina* intended for stocks should be put in in spring, selecting the young straight shoots of the previous season, about six inches long, or according to fancy; about September is the best season for grafting *Epiphyllums*. The scion should consist of one or two joints; cut the outer bark off about one inch on each side of the scion, split the stock about the same length, put the scion in, and tie or pin it with a thorn, according to which stock you use; the plants must then be put into a close frame, and laid on their sides until united, which they will do in about six weeks, when they may be placed upright, and gradually hardened off. Most of the species may be raised from seed, which should be sown as soon as collected, if possible, and put into a temperature of 60°. The young plants grow very slowly at first; when potted off they should be placed near the light; it is best to let them remain in the seed-pot until the following season, as they are very apt to damp if they are potted off too soon. Seed collected

abroad should be left in the pulp, which being its natural protector prevents the air acting on it, and drying it up; packed in a small tin box it may be sent any distance without losing its vitality. The best flowering varieties are *Cereus speciosissimus*, and its varieties, as *C. Ackermannii*, *Jenkinsonii*, *splendens*, and others; these are the forms most commonly grown in cottage windows; the genera *Phyllocactus* and *Cereus* contain many fine flowering varieties.

Hybridization may be performed with ease as the stamen and pistils are so very distinct, and the pollen produced in abundance. It may be preserved for some time if kept in a bottle hermetically sealed. I have not met with any successful attempt to cross *Mammillaria* with *Echinocactus*, or *Opuntia* with *Cereus*, though I know of no cause why they may not be, as the differences in the flowers are not differences of structure, but merely degrees of development; such as a greater or lesser number of stamens and petals, or in the absence in some, and lengths in others of the tube of the corolla, excepting that it may be that the pollen tubes might be too strong for the distance they have to grow from the apex of the stigma, or *vice versa*.

CONCLUSION.

The chief points to be observed in the above directions are, the light, time, and mode of potting, taking special care not to be afraid to cut off the roots. The watering, which should be given with a rose on the pot, should be sufficient to thoroughly soak the soil; it is best to hold the pot as high as you can, so that the water may fall on all parts of the plant, which serves the double purpose of washing and watering at the same time. Be sure to give them a good drying in the winter, upon which depends the success in flowering them the next season.

Some few species, as *Opuntia vulgaris*, and *Rafinesquiana*, and *Echinopsis Erytrea*, are hardy in the south of England; and I have no doubt that many species of *Opuntia* and *Echinopsis* would do very well in cold frames in winter, and the open air in summer. For an amateur, the Cacti are the best plants to cultivate, as they offer the greatest scope for number of species, and require so little attention. In a house twenty feet by twelve feet from four hundred to five hundred species may be grown; in the summer the house can be left night and day with air, and if the owner had no person he could trust, he might lock the house, and leave them a week at a time without fear of harm. In the winter, if he should be obliged to leave home, the only thing would be to get the heat looked after, and his pets would welcome him home with as fresh an appearance as when he left. One often hears the remark from some person who has been disappointed—I bought some in the market, but they soon died; the fact is, these plants are newly potted, and should be treated as advised for fresh-potted plants. Cacti intended for exportation to long distances should be laid in the sun until they begin to shrivel, when they should be packed in some coarse material, as straw, taking care to use enough to prevent the spines of one piercing the other; for if one begins to rot, all will soon become moist, and endanger the whole cargo. Holes must be made in the sides of the boxes, to cause a current of air to pass through, as a safeguard against accidents.—*Student*

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Grevillea Mangelsii.—We strongly recommend this plant to all our readers who have to embellish conservatories and winter gardens. A specimen of it which we saw at Glasnevin was about ten feet high, with a peculiarly graceful habit—quite unlike that of any of its relatives, and having a very enticing resemblance in habit to the Weeping Willow. It will probably do for large conservatories what that fine plant does for our pleasure-grounds. It is abundantly covered with white flowers in spring, but the drooping character of its slender branchlets is its chief charm.—W.

Triteleia uniflora as a Pot Plant.—I noticed at Chiswick the other day a large quantity of this potted in forty-eight sized pots, about eight plants in each pot. They were beginning to throw up flowers, and will doubtless be found useful for the decoration of the conservatory at South Kensington. For borders this *Triteleia* is by no means to be despised; it seems capable of withstanding the hardest frost without injury, and is therefore well adapted for outdoor cultivation. It blooms freely, and the ent flowers can be mingled with others without the unpleasant smell which unfortunately belongs to them being discernible.—R. D.

Hebeclinium ianthinum.—This useful winter-flowering plant appears to be but little known, notwithstanding its being of easy culture and a free bloomer. Its large heads of flowers, which are of a fine purplish mauve colour, are elevated on the points of the branches, well up above the leaves, and thus are shown off to good advantage. An intermediate house suits it best, and it may be grown successfully in a compost of two parts loam, one of leaf mould, one of well-decomposed manure, with a little sharp sand. After the blooming season is past, allow it to rest for a while

then cut it back to within two eyes of the old wood, and place it for a time in a close moist atmosphere.

Salvia splendens.—I have often had plants of this four or five feet high, and as much through, in one season from spring cuttings, and covered with flowers from October till Christmas. Put in the cuttings in February or March; when rooted put off, and grow on in heat till May, then harden off, and plant them out in the kitchen garden or reserve ground about four or five feet apart. If dry weather sets in, mulch with a little coco fibre or short manure, and water them occasionally; sprinkle them overheard in the evening after hot, bright days, pinch in all strong shoots to induce a close compact habit, giving the last pinching about the 1st of August. After this period water more sparingly, but still continuo the evening sprinkling. All the growth made now will be flowering growth, and the object should be to obtain short-jointed, moderately strong shoots. About the first week in September cut round the plants with a spade about a foot from the stems, so as to sever all roots that extend beyond that distance. In a fortnight all may be potted, placing them afterwards in a shady position for a few days, and supply them well with water. In potting lift them carefully with balls. The largest plants will require fifteen-inch pots. Securo the strongest shoots neatly with stakes, as the branches are apt to split off if left without support. House them before frost supervenes, and they will form superb flowering specimens.—E. Hobday.

THE HOUSEHOLD.

THE "WHY" IN VEGETABLE COOKERY.

BY MRS. WARREN.

Why should Seakale never be boiled in plain boiling water, but in milk and water and salt; or, instead of milk, a little bacon fat, butter, lard, or beef dripping?—Because kale requires to be cooked in soft water and be kept of a good colour. Soda would soften the water, but turn the kale black. Equal parts of milk and water may be used, but then milk is expensive, while by using a little fat in the water the kale is equally good, and is not greasy when served.

Why should Celery for sauce or for stewing be boiled in a little milk, butter, and salt, and with sufficient water to very little more than cover it?—Because it requires soft water to cook it in, and the milk and water in which it is cooked will, after the celery is dressed, serve for sauce if it be thickened with one or two tablespoonfuls of corn-flour mixed with a little milk, and adding it to the celery and liquor it is in. It is then converted into a thick sauce, and served as such, or if for stewed celery the latter can remain in the sauce till wanted, then be placed in a dish, and the sauce strained over it.

Why should Carrots not be split for boiling?—Because the flavour is entirely lost by splitting them. They require boiling in soft water; soda would blacken them. Some fat, as dripping or other fat, should be put in the water when it is put on cold; when it boils fast put in two ounces of salt and the carrots whole or cut across, *not split*, and boil them two hours after they have boiled up. These directions are for boiling carrots in winter.

Why should summer Carrots not be scraped?—Because the delicate flavour would be spoiled. They should be washed clean, be put into boiling water with a little fat and salt, be boiled from fifteen to twenty minutes, then be strained and thrown into cold water. With a clean cloth rub off the outside skin, and throw each carrot as it is done into hot water till the moment of serving.

Why should Parsnips not be split for cooking them?—For the same reason as for carrots—splitting destroys the flavour. They should be boiled as directed for carrots, but only for twenty minutes, half-an-hour, or an hour, according to the size—the largest only an hour.

Why should Soda be boiled with greens, cabbages, broccoli, and turnip greens?—Because the oil which all these vegetables contain more or less the soda extracts, and leaves the greens sweet and wholesome; but the water is, after boiling the greens with soda most unwholesome, perhaps poisonous. How wrong then it is to eat greens not cooked with soda. A piece of soda, fiber size, is sufficient for a very large sauceman of boiling water. Turnip greens have scarcely any oil in them, but are nevertheless much more wholesome for eating when cooked with a little soda. From the seed of cabbage the colza-oil is manufactured.

Why should Vegetables be washed in rather warm water first, then in cold, to cleanse them from sand and insects?—The hot water, which must be hotter than tepid, causes the insects and sand to fall out at once. Insects do not always dislike cold water and salt, but the hot water kills them. It must be understood that only a small handful of greens or one head of cabbage at a time must be washed, and then instantly thrown into the cold water, which crisps and thoroughly cleanses them. Spinach, leeks, celery, and seakale are thus rendered very clean, and, moreover, are very rapidly cleansed. It is worse than useless to attempt to cleanse vegetables in salt and water. The hardness which salt creates in the water prevents all

cleansing properties. The salt may kill the insects (it does not always do this), but they stick on hard and fast; the hot water makes them fall out at once, and the cold water crisps and also blanches them.

Why should Savoy Cabbages, white-heart summer cabbages, and cabbages that have been a long time growing, be cut across the ribs of the leaves, and not lengthways?—Because all cabbages that have been a long time coming to maturity have extremely tough fibres; if these are cut lengthways one has to chop the fibres with the teeth in eating them, and, moreover, such cabbages take a longer time to boil, and are often served a tasteless, overdone, watery mass. If such greens be cut across the stems, in circles of two inches in width, be washed in warm water, then in cold, and be boiled in boiling water with salt and a little soda for from fifteen to twenty minutes, not a moment longer, if so long, the greens are sweet and exceedingly tender and wholesome, purifying the blood and promoting health. A dish of badly cooked greens is enough to create a severe fit of indigestion in those who eat them.

Why should the stems of hard white Cabbages be never cooked with the other parts of the cabbage?—Because they take twice as long to cook as the soft parts, so that the latter is an unwholesome waste before the stalks are done, and if they are thrown away either before or after cooking them it is waste. The stems of cabbages that are crisp should have the soft green part cut from them to be cooked by itself; the stems when stripped from the green be tied in small bundles, cooked for twenty to twenty-five minutes in plenty of boiling water, salt, and a little soda, and be served with butter sauce over them. Then a dish of seakale is not more delicious. These cabbage stems may be called "chardloons," and will gratify the palates of all who taste them thus cooked. Young spring cabbages, of course, do not need this treatment.

Why should turnips be cut across the fibre in rings of less than half an inch in thickness?—For three reasons: first, the turnip need only be peeled very thin, instead of in the usual manner, thickly and wastefully; secondly, by so cutting them the fibres are cut across, so that however old the turnip, it is never stringy; thirdly, they require only fourteen minutes to boil in plenty of boiling water and salt, and thus the delicate flavour of the turnip is preserved, also they can be more easily mashed. The thinner the circles of turnip there are, the quicker they cook and the less fibre they will have.—Treasury of Literature.

Tomato Salad.—I give you directions for making tomato salad which I learned from an American gentleman in Switzerland last year. Take well mixed English mustard, salt, and pure Luca olive-oil; put a spoonful of mustard in the middle of a plate, half a salt-spoonful of salt on it, and mix them with a silver fork; on this pour a little of the olive-oil; stir this round and round until the oil is mixed; pour a little more oil, stirring it round as before, keeping it well together to prevent spreading; on this pour a little more oil, rubbing it round and round with the silver fork; and so on again and again, until the mixture becomes about the size of a small teacup standing on its mouth. Remember it should get plenty of quick tidy rubbing with the fork until each addition of oil is thoroughly absorbed. The mixture will be so adhesive that it may be helped with the fork. In this mixture the sliced tomatoes are placed. They should be red ripe, and perfectly fresh. When sliced, vinegar should be poured on them, according to taste, or not, if preferred.—E. E. F., in "Irish Farmer's Gazette."—[Vinegar is not used with a properly-made tomato salad in America.]

Red Peppers—try them.—One day when we were in New York I turned into the Fifth Avenue Hotel, on the prowl for something for my inner man, and, feeling the gregarious instinct strong upon me, went and sat down by the only other occupant of the saloon, a long, cadaverous Yankee, just that sort that Tenniel always puts into his cartoons, with stripy trousers and a starry shirt, to typify Cousin Jonathan. I had come across a good many strange vegetables since we landed in the States, but a dish of reddish somethings, which my gaunt neighbour was devouring with apparent relish, struck me at once as a novelty. "May I ask what they are?" "Red peppers—try them." Innocently I accepted the invitation, and the moment I bit one of the things, felt—how shall I describe the sensation?—well, as if a red-hot poker had been laid on my tongue. Luckily, just before screaming out, I caught the eye of my cadaverous enemy fixed upon me with a queer, amased, half-malicious look, that told its tale in a moment. He was bent on teaching the benighted Britisher a lesson, and it was the benighted Britisher's bounden duty to refuse him that satisfaction. So, by a severe muscular effort, I strangled all outward facial signs of pain, and slowly chewed my agonising mouthful before my torturer's eyes till it was fairly swallowed. At last he said, rather impatiently, "How do you find the peppers, sir?" "A little warm," I answered, calmly; "but, (forgive me the fib!) a nice kind of vegetable, decidedly;" "But you needn't be afraid of the next world, then," he jerked out, and, though evidently disappointed, treated me with decided respect from that moment.—Macmillan's Magazine.

THE ARBORETUM.

THE PLANES.

BY GEORGE GORDON, A.L.S.

The different species of this noble family are natives either of Asia Minor, Western India, the south of Europe, or North America; and are all more or less lofty trees (with the exception of *Platanus cuneata*), furnished with spreading branches, large deciduous palmate leaves, and bark which scales off the stems and main branches in irregular patches annually. None of them, however, attain their true tree-like character or appearance until after being planted about twenty years. The Planes are only valued as ornamental trees or for shade, as their timber is short grained, and soon perishes if exposed to the sun and atmosphere.

The genus *Platanus* constitutes a small natural order called Platanaceæ, which is easily distinguished by its globular catkins or round balls of unisexual flowers produced on long pendent axillary peduncles, sometimes six inches in length, and bearing from two to six balls or heads, which generally

Leaf of the Occidental Plane.—Natural Size 9½ inches by 9½ inches, including Footstalk.

remain on the tree until the following spring, when they break up and scatter abroad the seeds. The seeds when deprived of their down are brown, linear, and smaller than those of the lettuce.

I.—THE OCCIDENTAL, OR GREAT WESTERN PLANE (*PLATANUS OCCIDENTALIS*—LINNÆUS).

This kind is much loftier, more open in the head and has longer stems than any of the other Planes. The stems of large trees are smoother, of a lighter colour, and throw off the bark, sometimes in one part and sometimes in another, in larger and more irregular scales than any of the other kinds.

The Occidental Plane is found over an immense tract of land in North America, comprising the Atlantic and Western States, where it grows, along the banks of rivers and in moist situations, to an enormous size. The elder Michaux, in his "Flora Boreali Americana," says he measured a tree on a little island in the Ohio River, which at five feet from the ground was forty feet in circumference. The younger Michaux also measured another tree growing on the right bank of the same river, the base of which was swollen in an extraordinary manner, and which at four feet from the ground measured forty-seven feet in girth, and only began to ramify twenty feet from the ground; he also states that he saw several old trees which had not a branch within sixty feet of the ground.

Dr. Mease, of Philadelphia, gives an account of an Occidental Plane which he saw in 1836 growing near Howell's Ferry, on the York side of Broad River in South Carolina, which, for its great size and capacity, perhaps surpasses any one in the United States; its circumference was seventy-two feet, with hollow sixteen feet in diameter, and which at one time held within that space seven men on horseback. All the large Plane trees in the London squares are of this kind.

The leaves of the Occidental Plane are large, broadly five-lobed or angled, with a few large acute serrations along the margins, and mostly cordate or truncate at the base, and when they first appear are covered all over with a dense, rusty-coloured tomentum or silky down, which sheds off by the time the leaves are fully developed, when they become glabrous, and bright-green above and paler beneath, with a little tomentum in the axils of the veins and on the principal ribs. The flowers, which appear in May, are in close balls or heads, on long peduncles, bearing from two to four on each, and which balls, when fully-matured, are in general much larger than those of the Oriental Plane (not smaller, as stated by most writers), and at a much greater distance apart on the peduncles, and with the external elevations much larger and quite smooth, except at the base. The fruit or balls are also less thickly covered with bristly points than those of the Oriental Plane; but these points in a great measure disappear during the winter, so that the round balls appear comparatively smooth before they break up in the spring. The seeds are little things in the shape of a round nail without a head. The American names for this tree are Button Wood, Water Beech, and Sycamore.

There are several seedling varieties of the Western Plane enumerated in catalogues, but none of them retain their distinctive characters when the tree becomes large, except the pyramidal and variegated ones; the former of these is desirable on account of its erect habit, while the latter, which is by no means permanent in the variegation, is hardly worth preserving.

[This and many forthcoming articles by Mr. Gordon, will be illustrated by engravings of authentic specimens from his rich herbarium of hardy trees and shrubs.]

FAMOUS TREES.

THE GREAT CHESTNUT OF MOUNT ETNA.

(“IL CASTAGNO DI CENTO CAVALLI.”)

THE Chestnut, in a soil and situation that suits it, often becomes a noble forest tree in this country, and the symmetrical ridges of its peculiar bark render it a very conspicuous and easily recognisable object in our woods. It does not, however, attain its fullest dimensions on the northern side of the Alps; and not till we have passed the mountain chain which separates Spain, Italy, and Greece from Central Europe do we behold the Chestnut in all its glory. On the southern slopes of this mountain chain, much finer trees than any in England, France, or Switzerland already begin to appear, luxuriating grandly in their bright southern aspect; and as the traveller wends his way further southward, he finds this handsome tree still increasing in size and in magnificence of growth; especially in the south of Italy and Sicily. At the base of Mount Etna, and at a certain elevation, commences what the natives call the “Regione Sylvoso,” that is to say, the woody region, consisting of a great ring of forest that girds the entire base of the mountain. Part of this forest girdle was utterly destroyed in 1755 (the year of the great earthquake of Lisbon) by a devastating eruption from the great crater, consisting not of lava, but of boiling water, which proved fatal to every kind of vegetation in its course. The track of the exterminating torrent is still visible, there being no trees of great size in any part of its course, as at other parts of the forest region.

In the lower girdle of wood, Cork trees and evergreen Oak

OLD CHESTNUT ON MOUNT ETNA.

predominate, often growing actually out of the hard lava; but in the higher portion of the woody girdle, at an elevation of between three and four thousand feet, the Chestnut is the principal tree. The elevation and the soil (consisting chiefly of ashes in an impalpable powder) appear to suit it in a remarkable manner, for the trees of that region attain a truly gigantic growth, numbers of them being far above the average size of the largest forest trees of Europe. The "Castagno di cento Cavalli" is, however, by far the most celebrated, and is actually found marked in Sicilian maps published a century ago, while in all modern charts of Etna and its environs it forms a very conspicuous figure. Its aspect on a first approach is, however, disappointing; the trunk becoming hollow, the weight of its branches have rent it asunder, leaving a considerable space in the centre; and the tree, in its severed state, looks much like a group of five distinct trees partially decayed. Many have, in fact, insisted that the five separated portions never could have formed a single trunk. But there are old men now living, grandfathers of the present generation, who recollect the five huge fragments united in one stem, and who aver that it was regarded in their time as the glory of the forest, and visited by travellers from all parts of the world, though it is now but a venerable ruin.

That it was originally one compact and gigantic tree is partly proved by the fact, that on the inner side of the vast segments of trunk that still stand round the large open space that was once the core of the tree, there is no bark; and the original unity of the tree has been further demonstrated by an excavation made a few years ago by the Canonico Recupero, when it was found that at a certain depth below the surface the five separated portions united in one solid trunk; the entire circumference at the surface being found to be 204 feet, giving a diameter of 68 feet.

The Sicilian historian, Carrera, who saw the tree when in all its grandeur, remarked that there was wood enough in it to build an immense palace.

The native poet, Bagolini, has celebrated in tolerably good Latin verse the grandeur of an enormous Chestnut growing on the flank of Etna, which was probably no other than the "Castagno di cento Cavalli;" so called, no doubt, because a hundred horses could be sheltered from the scorching rays of the Sicilian sun beneath its far-reaching arms and dense foliage.

Bagolini's verses may be thus Englished:—

" Of lofty montes, by far the loftiest,
Prodigious Etna, bore a wondrous tree,—
A Chestnut, whose vast hollow may contain
A numerous band of horse, or flocks, or herds;" * &c.

It will be seen that these lines were written after the trunk of the vast tree alluded to had split into segments, and left a considerable space in the centre, similar to that of the tree under description; but whether that special tree be the one referred to, or some gigantic predecessor, is uncertain, and, in fact, matters little.

If some other tree be alluded to, it serves to show, as about to be asserted, that Chestnuts of enormous size were not of unfrequent occurrence in those regions. Massa, one of the most esteemed of Sicilian authors, states that though he had himself seen Oaks, sound and solid, measuring more than forty feet round, he had seen Chestnut trees of far greater dimensions; trees which were, in fact, of such a size as almost to exceed belief. One in particular is mentioned by him, the hollow of which was capable of holding three hundred sheep.

There are, indeed, great Chestnuts at the present time in a sound growing state in the Etna Forest, which are of extraordinary size. The largest of these is about a mile and a half higher up the mountain than the celebrated old tree, and is called "Il Castagno del Galea." It rises on an erect and solid stem to a considerable height, when it spreads forth great arms of enormous size, and is, in fact, a much finer object than the venerable ruin of the *cento cavalli*. Two feet from the ground it is seventy-six feet in girth, and twenty-

five feet four inches in diameter; the spread of the massive branches being of fully corresponding extent. Another great tree, of nearly equal size, is known to the Etna guides as the "Castagno del Nave." Both of these, and many others of but slightly inferior dimensions, grow in a deep rich soil formed by the ashes thrown out of the volcano, and are found at an elevation of about four thousand feet; below three thousand feet the heat being too great to permit of the luxuriant vegetation of trees of this class. In our engraving the venerable Chestnut of "the hundred horses" is represented to the left, and towards the centre and right is shown the neighbouring portion of his forest brethren. Near the top, to the right, is the summit of the mountain, with a faint cloud of smoke issuing from the great crater.

H. N. H.

EFFECTIVE TREE-GROUPING.

It is one thing to plant, and almost anyone may in some way accomplish the task; but it is another thing to plant effectively; for it needs a true artist to do this successfully. A wide range of acquaintance with the aspects, habits, and dimensions of plants, their development of special features, times of flowering, alteration of tint, the positions best suited to bring out their beauties, or to be beautified by them, are all matters of importance, and calculated to tax the skill and taste of the most experienced and accomplished.

Grouping is a department of ornamental planting at once the most effective and the most difficult. There is a wide difference, let me observe, between a group and a clump. The latter is usually a mass of planting, formal and monotonous in aspect; whereas, the former should present an infinite variety of form and outline, all the material of which it is composed retaining a certain amount of individuality, and yet blending in happy and graceful unison, free from trim formalism, as also from absurd incongruity; and he who would accomplish the art of thus planting, cannot do better than become an earnest student of nature herself, gleaning his lessons from the sky-line of the mountain, the swells and hollows of the forest, and the meanderings of the watercourse. As a rule, groups should be bold and dense; anything like thinness has a mean and poverty-stricken aspect, which should be carefully avoided.

The outlines of groups, both on the ground and against the sky, should be carefully designed; the ground lines should be easy and flowing, free from false curves and anything approaching to rigidity; the sky-line widely diversified, but ever harmonious—here rendered striking by the upshooting of some plant of distinct character, anon merging easily and naturally into lines of smoothness, graceful as those of nature herself. Thus will be secured those exquisite effects of light and shade so full of charm and beauty to the eye capable of their appreciation. These features are of the greatest importance in the immediate vicinity of water, where shadows and reflections are ever changing and ever new. Again, park and other like groups should always be accompanied by a few irregularly-planted trees, such as thorns, &c., especially at their salient points; this happily removes all stiffness, and gives a natural expression to the whole.
